THIS work was prompted by the following chance observation While examining acid-base metabolism in the turtle, *Pseudemys scripta elegans*, a series of measurements of plasma *p*H and carbon dioxide tension was performed on a group of turtles in Pittsburgh, Pennsylvania As shown in Table 1, control values of *p*H averaged 7 49 and of carbon dioxide tension averaged 41 mm mercury However, measurements of these parameters in another group of turtles of the same species performed in Salisbury Cove, Maine, showed an average *p*H of 7 72 and an average carbon dioxide tension of 20 mm mercury The only obvious difference between the two groups was the ambient temperature of each group Turtles in Pittsburgh were maintained indoors at a temperature between 26° and 28° C Turtles in Salisbury Cove were stored out of doors at an average temperature of 16°–18° C It seemed of interest to investigate the relationship between temperature and plasma carbon dioxide tension and *p*H

Table 1 A COMPARISON OF PLASMA *p*H AND CARBON DIOXIDE TENSION IN PITTSBURGH AND IN SALISBURY COVE IN THE TURTLE

	No of measurements	Mean plasma *p*H units	Mean plasma CO_2 tension mm Hg
Pseudemys scripta elegans (Pittsburgh)	5	7 49	41
Pseudemys scripta elegans (Salisbury Cove)	34	7 72	20

A group of 11 turtles (species, *Pseudemys scripta elegans*) weighing 0 5–1 0 kgm was studied Each turtle was exposed to temperatures of approximately 10°, 24° and 37° C The length of exposure at each temperature was approximately 24 hr The order of exposure was varied among the turtles so that all three possible orders of exposure were represented At the end of each 24-hr period, heparinized blood for analysis was obtained anaerobically by means of direct intracardiac puncture through a hole drilled in the plastron Between cardiac punctures, the hole in the plastron was filled with bone wax *p*H measurements were performed anaerobically by means of a standard glass electrode using an Instrumentation Laboratory *p*H meter These measurements were performed at each ambient temperature (presumably this represented the internal temperature of the turtle as well[1]) that the animal was exposed to In some animals whole blood total carbon dioxide contents were measured in a Van Slyke apparatus by the technique of Van Slyke and Neill[2] and carbon dioxide tensions calculated by means of the Henderson–Hasselbalch form of the mass action law from the plasma *p*H, the total carbon dioxide content of whole blood, the hæmatocrit, the temperature-corrected *p*Ka′ (ref 3) and a temperature-corrected carbon dioxide[4]. In other animals, carbon dioxide tensions were measured directly at the given ambient temperature by means of a Severinghaus electrode[5]. In these animals, plasma bicarbonate concentration was calculated by the Henderson–Hasselbalch statement of the mass action law using a temperature-corrected pKa' (ref. 4) and temperature-corrected carbon dioxide[5]. Comparisons between directly determined carbon dioxide tensions and calculated carbon dioxide tensions were performed on 5 bloods at the three temperature-ranges and were not significantly different.

The *in vitro* influence of temperature on turtle plasma *p*H, carbon dioxide tension and bicarbonate concentration was studied as follows. Blood was obtained from seven animals by intracardiac puncture in the usual fashion. Plasma *p*H's and carbon dioxide tensions were determined successively at 37°, 24° and 10° by direct measurement. Plasma bicarbonate concentrations were calculated as described here.

The *in vivo* data concerning the effect of temperature on carbon dioxide tension, *p*H and bicarbonate concentration are summarized in Tables 2, 3 and 4. It can be seen that, invariably, an increase of ambient temperature results in an increased plasma carbon dioxide tension. There is, on the average, an approximately three-fold increase in plasma carbon dioxide tension between 10° and 37° C. Corresponding changes occur in plasma *p*H so that plasma hydrogen ion concentration increases with exposure to higher temperatures. However, the fall in *p*H does not occur invariably in every animal. The changes of *p*H at 10° C and at 37° C and at 24° C and at 37° C are statistically significant at a $P < 0.001$ level. Those between 10° and 24° are significant at a level of $0.1 > P > 0.05$. The failure of *p*H to change to a greater extent between 10° and 24° in some animals probably reflects more effective renal compensation.

The mean changes in bicarbonate concentration are in the expected direction with the highest average plasma bicarbonate concentration being found in the animals at 37° C and the lowest in the animals at 10° C. There is considerable individual variation in this relationship again presumably reflecting different degrees of renal compensation.

11	23.2 (*c*)	31.6 (*b*)	30.2 (*a*)
Mean	30.0±6.4	33.8±6.0	36.0±4.6

$0.1 > P > 0.05$ for values obtained at 10° and 24°; $P < 0.05$ for values obtained at 10° and 37°; $P < 0.2$ for values obtained at 24° and 37°. *a*, *b* and *c* indicate order of exposure as in Table 2.

The *in vitro* data are summarized in Table 5. An increase of temperature invariably results in an increase of carbon dioxide tension and a fall in *p*H. The mean values of bicarbonate concentration are essentially the same at all temperatures. The individual calculated bicarbonate concentrations at 10° tend to show relatively poor agreement with the values calculated at 24° and 37°. This poor agreement is probably related to the relative inaccuracy of the assumed α carbon dioxide at this temperature and on the fact that small inaccuracies of *p*H and plasma carbon dioxide tension will produce large differences in calculated bicarbonate concentrations.

The relation between temperature and acid-base metabolism is of considerable theoretical interest. The magnitude of temperature change in this study is probably not significantly different from temperatures that the turtle is subjected to during the course of ordinary existence since, during the winter, ambient temperature may be as low as 10° C and during basking in the Sun may probably come fairly close to 37°.

The obvious mechanism for the changes is the effect of temperature on the solubility of carbon dioxide gas at various temperatures, and the increase of H^+ activity that occurs with increasing temperature. An increase in temperature results in an increase of partial pressure of most gases in aqueous solution.

That this is indeed the basis of the observed changes is indicated by the results obtained, *in vitro*, in isolated turtle blood, which show that an increase of temperature is invariably associated with a rise in carbon dioxide tension and a fall in *p*H In the isolated closed physical-chemical system (the blood manipulated outside of the turtle), the direction and magnitude of the changes are strikingly consistent and predictable In the more open and complicated physical-chemical system (the blood inside of the manipulated turtle), there is more variability because of the large number of additional mechanisms besides temperature which produce changes in carbon dioxide tension and *p*H But the fundamental importance of body temperature in establishing a given level of carbon dioxide tension and *p*H in both systems seems clear As a matter of fact, the effect of temperature on gas solubility applies broadly to all biologically important gases and must therefore be a factor in regulating the value of carbon dioxide tensions in all biological systems However, its operation in homotherms is difficult to demonstrate for two reasons (1) Changes in temperature in such animals are small in magnitude (2) Homotherms regulate carbon dioxide tension and *p*H by varying external ventilation in such a way that a constant carbon dioxide tension is maintained Such control is usually neurally regulated

Since the turtle does not maintain a constant *p* carbon dioxide when temperature of the body is varied, it seems likely that the regulation of ventilation in the turtle does not depend on the carbon dioxide tension or *p*H of extracellular fluid Little is known concerning the regulation of ventilation in reptiles, but the turtle does not overtly hyperventilate when placed in an atmosphere enriched with carbon dioxide (unpublished observations), and appears to breathe erratically rather than regularly under basal conditions, and can spend considerable time under water without manifest external ventilation

In a number of mammals, the central regulation of temperature and of ventilation appear to be closely related[6] If the relationship between temperature and carbon dioxide tension applies not only to the turtle but generally to poikilothermic animals, it may well be that the regulation of carbon dioxide tension and *p*H within narrow limits is, from the evolutionary point of view, a temperature-dependent function

It seems clear that the maxim that 'life can only exist within a relatively small *p*H range' is not applicable to the turtle and may only be true of homothermal animals

RELATIVE IMPORTANCE OF DRY- AND WET-BULB TEMPERATURES IN CAUSING HEAT STRESS IN CATTLE

By Dr. W BIANCA

Department of Physiology, Hannah Dairy Research Institute, Ayr

THE two principal climatic factors which determine the stress imposed by a hot indoor environment are the dry-bulb and wet-bulb temperatures In man, wet-bulb temperature has been found to be far more important than dry-bulb temperature Indeed, wet-bulb temperature alone has experimentally been shown to be a useful indicator of heat stress[1] Where dry- and wet-bulb temperatures have been used in combination, wet-bulb temperature has always been regarded as being 5–10 times more important than dry-bulb temperature Recently, Provins, Hellon, Bell and Hiorns[2] obtained a clearly defined curve when plotting tolerance times of subjects resting in hot environments against the weighted scale dry-bulb × 0 15 + wet-bulb × 0 85

In cattle it is generally recognized that a high wet-bulb temperature causes more stress than a high dry-bulb temperature, but the relative importance of the two has not been defined An attempt has therefore been made to find what weighting factors for dry- and wet-bulb temperatures would be appropriate in cattle

Four Ayrshire bull calves, 9 months old, were simultaneously exposed in a climatic room to nine different environments (Table 1) The environments numbered 1–5 ranged from 30° to 50° C dry-bulb temperature at a constant dew-point temperature of 17 5° C The environments numbered 6–9 were at constant dry-bulb temperature of 40° C , that is, at approximately body temperature, with the dew-point temperature ranging from 8 3° to 30 6° C The corresponding wet-bulb temperatures are given in Table 1 Each animal was exposed three times to each of these environments for 5 hr at a time The resulting strain was expressed in terms of the rectal temperature recorded at the end of the 5-hr period and the mean values obtained were plotted against the weighted scale dry-bulb × 0 15 + wet-bulb × 0 85

Table 1 DRY-BULB (DB), WET-BULB (WB) AND COMBINED TEMPERATURES OF THE NINE EXPERIMENTAL ENVIRONMENTS

Environment No	DB °C	WB °C	DB×0 15+ WB×0 85 °C	DB×0 35+ WB×0 65 °C
1	30 0	21 5	22 8	24 5
2	35 0	23 0	24 8	27 2
3	40 0	24 4	26 7	29 9
4	45 0	25 7	28 6	32 5
5	50 0	26 9	30 4	35 0
6	40 0	20 4	23 3	27 3
7	40 0	25 1	27 3	30 3
8	40 0	29 1	30 7	32 9
9	40 0	32 5	33 6	35 1

It is evident from Fig 1 that the two sets of conditions, namely the environments 1–5 (which will be referred to as *A*) and the environments 6–9 (which will be referred to as *B*) gave divergent results There was good agreement between the rectal temperature responses to the environments 3 and 7, which were at the same dry-bulb temperature and at only slightly different wet-bulb temperatures The average rectal temperature attained after 5 hr in these two environments was 39.56° C and corresponded to 27° C on the weighted scale. However, below 27° C the curve for the responses to the *A* environments was below that for the responses to the *B* environments, above 27° C the situation was reversed. The two divergencies were almost symmetrical.

This finding indicates that the dry-bulb temperature had a much greater effect on the animals than was commensurate with a weighting factor of 15 per cent. In other words, a weighting of 15 per cent dry-bulb, 85 per cent wet-bulb temperature underrated the effect of dry-bulb temperature and overrated the effect of wet-bulb temperature.

Other dry-bulb–wet-bulb temperature combinations were therefore investigated, and it was found that with a weighting of dry-bulb × 0.35 + wet-bulb × 0.65 the rectal temperature responses to the environments *A* and *B* corresponded most closely (Fig. 2).

This means that whereas in man the effect of the wet-bulb temperature is almost six times as large as that of the dry-bulb temperature, in cattle it is only about twice as large. This difference could reflect species differences in the capacity for evaporation. According to Brody[3], on exposure to an atmosphere of 40.5° C, man can dissipate by evaporation of moisture about 190 per cent of his metabolic heat production, whereas European type cattle can dissipate only 105 per cent. Furthermore, in man evaporation occurs almost entirely from the skin, but in cattle it occurs from the respiratory tract as well as from the skin. Of these two modes of evaporation respiratory evaporation is less affected by a high air humidity than skin evaporation, because the air in the respiratory tract is normally warmer and therefore has a higher saturation vapour pressure than the air in contact with the skin. Indeed, moisture can be evaporated from the respiratory tract even in a saturated atmosphere, provided the temperature of the air surrounding the animal does not exceed the temperature of the air in the respiratory tract.

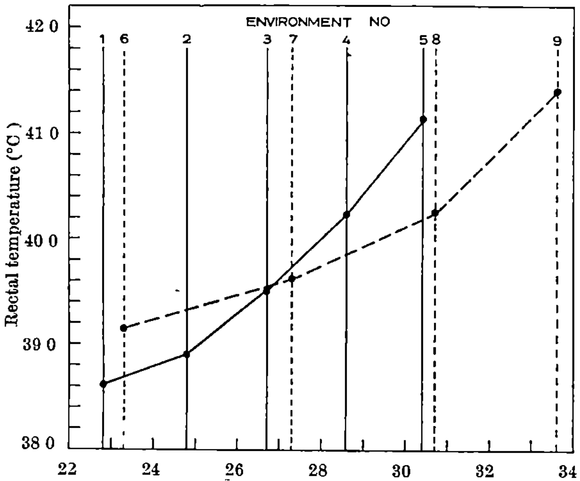

Fig. 1. Rectal temperatures of the calves after exposure to heat for 5 hr plotted against the weighted scale dry-bulb (DB) × 0.15 + wet-bulb (WB) × 0.85. Each point represents the mean of 12 readings.

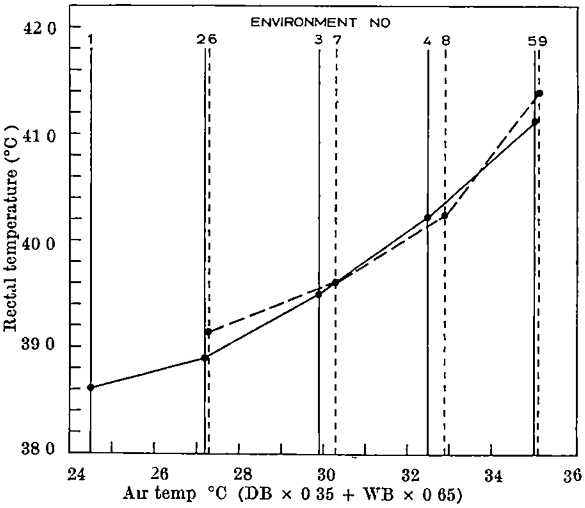

Fig. 2. Rectal temperatures of the calves after exposure to heat for 5 hr plotted against the weighted scale dry-bulb (DB) × 0.35 + wet bulb (WB) × 0.65. Each point represents the mean of 12 readings.

The weighting factors for dry- and wet-bulb temperatures arrived at in this work could become of practical value for predicting the heat strain imposed on cattle by various combinations of dry-bulb–wet-bulb temperatures. It would, however, be necessary to collect more data for the establishment of fiducial limits.

TWO OPPOSITE BEHAVIOURAL EFFECTS OF THE ELECTRICAL STIMULATION OF BRAIN STEM STRUCTURES IN FREELY MOVING MONKEYS

By Prof. JUHN A. WADA and JOHN WRINCH
Kinsmen Laboratory of Neurological Research, University of British Columbia, Vancouver

RAPID repetitive stimulation of the reticular core of the brain stem in freely moving animals has been reported to result in certain changes of behavioural state as well as electrocortical arousal. Such behavioural changes may range from awakening from natural sleep through the development of alert attitudes, to cowering or even frank flight[1]. Besides such global behavioural arousal, optimal stimulation may also produce a marked improvement in visual perception and motor reaction in tachistoscopic discrimination[2]. Entirely opposite effects, such as impaired performance of a learned task[3] or arrest of existent behaviour[4], have also been reported, and there is some evidence that 'a soporific effect on behaviour' may be obtained by electrical stimulation of certain points in the same functional system[5-7].

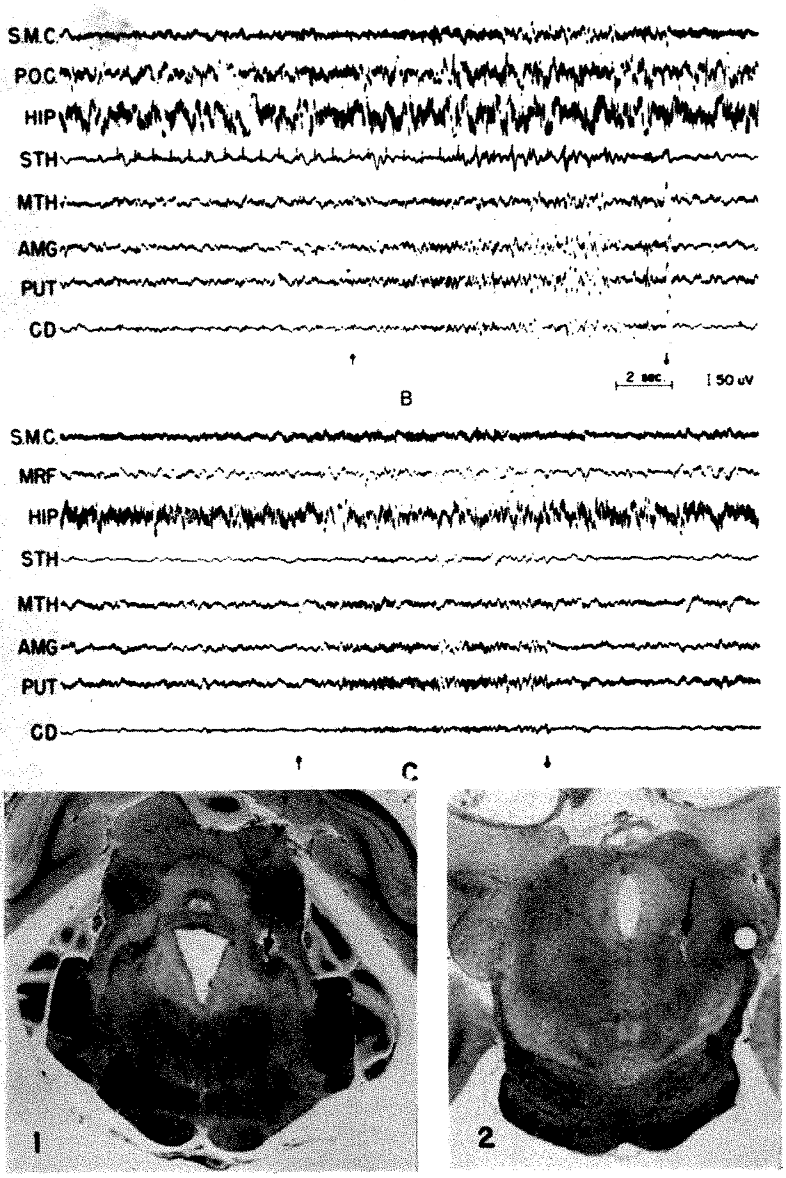

Fig. 1. Monkey "Goro". *A*, Behavioural sleep induced by reticular stimulation 4 V., 0·1 msec., 1·5 p.p.s. *B*, Spontaneous sleep. ↑ Closure of eyes after assuming sleeping position. ↓ Opening of eyes. *S.M.C.*, Sensori-motor cortex; *P.O.C.*, parieto-occipital cortex; *MRF*, mesencephalic reticular formation; *HIP*, hippocampus; *STH*, subthalamus; *MTH*, mid-line thalamic structure; *AMG*, amygdala; *PUT*, putamen; *CD*, caudate. *C*, Sites of stimulation. (1) "Goro". Electrode tip in the superior cerebellar peduncle. (2) "Saburo". Electrode tip in the lateral reticular formation

The frequency and nature of the electrical stimulation, as well as the environmental situation, seems to be important in obtaining the latter effect. Recently, we have been able to induce two distinctly opposite behavioural patterns by stimulating the same locus in the brain stem structures of macaque monkeys[8]. This communication is based on more than 100 observations on two monkeys during the last 10-month period. Each animal had multiple electrodes ('Teflon' coated bipolar platinum iridium wires separated 0·5 mm. at the tip) permanently implanted and was kept continuously in the observation box[8,9]. The behaviour was monitored through a one-way mirror system and the electrical activity was followed on a type 111*D* Grass electroencephalograph (EEG) and a DuMont type 332 oscilloscope. The EEG and behaviour of the animal were continuously and simultaneously cinematographed for later analysis. Electrical stimulation was delivered through the isolation units with two Grass type *S*4 stimulators using 1–200 p.p.s. at 2–8 V. and a 0·1 msec. square wave pulse duration. Electrode tips yielding the effects reported here were located in the lateral reticular formation (left) of one monkey and near the superior cerebellar peduncle (left) of the other (Fig. 1*C*).

(*a*) *Heightened Behaviour.* Behavioural arousal, ranging from alerting to a state of panic, followed repetitive high-frequency stimulation of the electrode sites shown in Fig. 1*C*.

The animal may be aroused from a natural drowsy state by 2 V., 0·1 msec., 200 p.p.s. If the same threshold stimulus was applied while the animal was awake, the only effect, and one consistently found, was that the animal raised its left hand and placed it on the edge of the collar plate. There was a few seconds latency for this action under the 2-V. stimulus, but this latency was practically eliminated when the voltage was raised to 2·5. Such stimulation by higher voltages was followed by a lifting of not only the left hand but also the right as well. When the left hand was occupied, as, for example, in holding a food pellet, the animal lifted its empty right hand. Since both animals were predominantly left-handed, it was easy to reproduce this last effect by offering them a piece of food immediately prior to the onset of brain stimulation. If the threshold brain stimulus was applied while the animal was engaged in eating from his left hand, his right hand was promptly raised and placed on the plastic collar, while the left hand remained unmoved or was lowered to the floor. Exactly the same behavioural patterns were repeatedly noted when the animal was alerted by an accidental noise. These findings seem to indicate that the lifting of the hand is not an involuntarily evoked motion but is an integral part of a voluntarily organized behavioural response in an alarming situation. As the voltage of the stimulation was further increased to 3·0, this 'prepared' behaviour was disorganized and replaced by sudden standing, rotation, aimless searching behaviour and other unmistakable patterns of panic. It seems possible that the stimulation of these electrode sites mobilized some neuronal system involved in the organization of patterned behaviour. This was evidenced by an appearance or disorganization of such behaviour depending on the intensity of stimulus applied.

(*b*) *Behavioural repose.* Low-frequency suprathreshold stimulation (6 V., 0·1 msec., 1 p.p.s.) of the same electrode sites where heightened behaviour was produced by high-frequency repetitive stimulation produced a slight twitching of the ipsilateral face and jaw following each stimulation. If the voltage was raised to 7, the jerking became so violent as to produce a noise of teeth cracking. When such a supramaximal stimulation was continued for more than 30 sec., the animal frequently began yawning. At this stage the animal kept its mouth wide open and thus minimized an annoying effect of the stimulation. Although the animal appeared to relax, sleep or a drowsy state never developed under these conditions (even if the stimulation was continued for more than 15 min.). A prolonged low-frequency, subthreshold stimulation of the same area, on the other hand, made the animal yawn, relax, assume sleeping position, close its eyes and finally go to sleep. The optimal stimulating conditions for evoking this reaction were found to be 4–5 V., 0·1 msec., 1·5–2 p.p.s. The onset of a relaxed behaviour progressing through drowsiness to sleep was accompanied by an electrographic pattern typical of similar states occurring spontaneously (Fig. 1*A*, *B*). Thus, the 30 c.p.s. fast activity in the depths as well as the surface usually observed at the onset was followed by rhythmic 3–5 c.p.s. slow wave bursts in the depths, the appearance of 10–12 c.p.s. high-voltage spindle bursts in the anterior cortices and the disappearance of lambda waves in the posterior cortex. Although this behaviour and electrographic state was repeatedly produced by stimulation of the brain, it could only be obtained if the environment was quiet. If a distracting stimulus was present, the animal did not sleep or relax. Furthermore, even after the animal closed its eyes and assumed a sleeping position, it could easily be aroused despite continued stimulus. The animal could also be awakened by simply changing to high-frequency repetitive stimulation after the animal had fallen asleep under low-frequency repetitive stimulation.

Sleep episodes commonly lasted 10–30 sec. in animals under low-frequency repetitive stimulation and, although repeated episodes could be induced, it has not been possible to make the animal sleep continuously. This finding suggests that the induced state of repose described here is probably due to facilitation of the mechanism of the onset but not the maintenance of sleep. It is possible that such brain stimulation, although unable by itself to affect overt behaviour, may, by its monotonous, repetitive nature, activate a process of inhibition similar to that of Pavlovian sleep. That such a process may involve more rostrally situated deep structures is suggested by the initial appearance of 30 c.p.s. fast activity in the prosencephalic structure. This assumption is in keeping with a recent disclosure that the caudate nucleus and its 'loop' serves as an integral part of inhibitory mechanism[10].

This work was aided by Federal Mental Health grant No. 609–5–129, the Provincial Mental Health Services of British Columbia, and the U.S. National Institute of Neurological Diseases and Blindness research grant No. *B*–2812. We thank Mr. Finn Bauck for assistance.

MENTAL STRESS AND ACUTE DENTAL CARIES

By Dr. PHILIP R. N. SUTTON

Dental School, University of Melbourne

AN indication that a period of severe mental stress may be followed by the development of acute dental caries, in adults, is suggested by results obtained recently.

This observation links with those of Findlay[1] on psychosomatic gingival conditions, associated with the progestational and menstrual phases of the cycle in young females, and with those of Robertson[2] on psychosomatic stress and pregnancy sickness.

Acute dental crown caries is a severe condition which causes rapid destruction of the hardest of all the body tissues—the teeth. The signs of this form of caries are considerably different from those seen in chronic caries, and include the presence of a white halo around the cavity and soft, yellowish-white carious dentine. Bodecker[3], in his classification of types of caries, said that acute caries is active "during childhood and up. Fifteen to twenty-five years". He stated that the clinical data in that classification had been approved by L. R. Cahn, H. Holliday, H. J. Leonard, E. C. McBeath, A. T. Rowe, L. M. Waugh and D. E. Ziskin. Thoma and Goldman[4] made a similar statement.

Attention was attracted when, within a four-day period, acute caries was observed in six patients who were more than forty years of age. Five of them, judging from their remarks, had recently been through a period of severe worry, and the sixth complained of severe overwork. Following this observation, during the examination of all patients who were twenty-five years of age or more, an endeavour was made to find out whether, during the preceding year, the patient had been ill, worried or overworked, and all cases of acute caries were recorded. None of the subjects disclosed any major changes in their dietary patterns or in their oral hygiene procedures.

Data were recorded for each of the 661 non-edentulous patients, of twenty-five years of age or more, who were examined, on one or more occasions, during the period July 5, 1957–December 31, 1960. Acute caries was observed in 169 subjects, and 175 subjects admitted having recently undergone severe mental stress. The circumstances given by them as the causes of their stress were as follows (the frequency with which each was reported is shown in parentheses): (1) Severe illness of (*a*) husband or wife (16), (*b*) child (14), (*c*) parent or other close relative (28). (2) Worry regarding own health (36); the descriptions given were—'nerves' (7), 'nervous breakdown' (2), hypertension (5), suspected cancer (3), migraine, arthritis, hyperthyroidism, failure of eyesight, recent operation (each two cases) and one case of each of nine other conditions. (3) Severe business or financial worries (29). (4) Changes in, or unsatisfactory, employment (15). (5) Housing or building worries (10). (6) Other reasons (35). (7) Stress admitted but cause not disclosed (23). (8) Twenty-seven patients complained of mental stress as a result of having been very overworked for at least a three-month period.

Forty-eight subjects reported two causes of stress and five disclosed three causes. 17 per cent of the women, but only 7 per cent of the men, did not disclose the cause of their stress, and, as would be expected, the proportion of men having business and financial worries (26 per cent) exceeded that found in these women (16 per cent); and whereas 54 per cent of the women who had recently undergone stress attributed it to illness (of others or of themselves), only 35 per cent of the men who had been under stress admitted worry of this nature.

In ten subjects acute caries was observed during examinations conducted several months apart. In each case the patient reported a prolonged period, or a resurgence, of stress. The onset of the period of worry or overwork preceded the detection of acute caries by periods varying from eleven to only two months. In most cases the stress was said to have been of several months duration; acute caries was not seen to follow periods of stress which lasted only a week or two.

In order to consider variable factors which may influence this comparison, the data were divided into sixty-four categories. Each of the two main groups of subjects—those showing and those not showing acute caries—was separated into two divisions according to sex, and each of these into four age groups (25–34, 35–44, 45–54 and 55 years and more), and each of these groups into four parts according to the number of natural teeth present in the mouth of each subject (1–14, 15–20, 21–26, 27–32).

In each age-group the incidence of acute caries was similar in both sexes (differences not statistically significant). In view of the opinion of Bodecker[8] that acute caries "affects principally children and young adults up to about the age of 25 years" it would be expected that the incidence of that condition would be highest in the youngest age-group. However, the highest incidence, 33 per cent, was in the 45–54 years age group. It was 27 per cent in the 25–34 years group and 20 per cent in both the 35–44 and the 55+ years groups. The incidence in the 45–54 years age group was greater (just significant at the 1 per cent level) than that of the combined data of the other three groups and significantly greater (at the 0·1 per cent level) than that seen in the 35–44 years and the 55+ years groups.

The mean number of natural teeth present in the mouths of those with acute caries and those without that condition were, respectively, in each age-group 25–34 years 24·9, 23·0 (difference just significant at the 1 per cent level); 35–44 years 23·3, 20·7 (difference significant at the 1 per cent level); 45–54 years 18·9, 19·7 and 55 years and over 14·5, 16·1—neither of the last-mentioned two differences being significant.

The unexpected result was obtained, in each age-group, that there was only a slight suggestion (not significant) that the incidence of acute caries was related to the number of teeth present. Therefore, the slight differences which have just been mentioned, in the two youngest age-groups, between the number of teeth present in those with and those without acute caries, are unlikely to affect the comparison.

The results obtained are shown in Table 1.

Table 1. INCIDENCE OF ACUTE DENTAL CARIES IN SUBJECTS AGED TWENTY-FIVE YEARS AND MORE WHICH WERE EXAMINED DURING THE PERIOD JULY 5, 1957–DECEMBER 31, 1960, SHOWING THOSE FROM WHOM A HISTORY OF RECENT MENTAL STRESS WAS ELICITED

The four figures shown in parentheses give the totals that would be expected if there were no relationship between acute caries and mental stress

Recent stress		Elicited							Not elicited			Totals
Acute caries		Illness of others		Illness of self		Other worry or overwork		Totals			Totals	
	Sex	M	F	M	F	M	F	M+F	M	F	M+F	M+F

Totals		13	38	7	26	37	54	175	198	288	486	661

Not merely when the data shown in Table 1 are considered as a whole, but also when those of each of the four age-groups in each sex are assessed separately, it is obvious that there is a strong suggestion that there is an association between mental stress and acute caries. However, these results are open to criticism on several grounds: (*a*) Although all patients, twenty-five years of age and more, presenting for examination were included in this investigation, the sample cannot be said to be a random one from the general population. (*b*) Despite the fact that the signs of typical lesions of acute and chronic caries are considerably different, there is no unmistakable line of demarcation between the two types. (*c*) There is considerable difficulty in assessing the presence of mental stress and reliance had to be placed on the statements made by the subjects. However, of those who admitted stress, almost half (81) said that this was due to, or accompanied by, illness that was receiving medical attention. The fact that the majority of these subjects have demonstrated some degree of confidence in the examiner, almost half of them having returned for treatment for ten years or more and an additional 28 per cent for more than four years, may be considered to reduce the likelihood of undue reticence on their part.

In those with acute caries, 96 per cent admitted recent severe mental stress, but in only 2 per cent of those considered to be free from acute caries was the presence of recent stress elicited. The former percentage is unlikely to be too high, for there would appear to be no reason for pretending that stress had been experienced, and all except 23 of the 163 subjects with acute caries and stress disclosed the cause of their stress. It is more likely that some of those without acute caries may have recently experienced stress but did not admit this fact. However, in the very improbable event that these subjects—

if there were any—numbered as many as 400 (that is, that 412 of those without acute caries had experienced stress), there would still be a strong suggestion that mental stress was associated with acute caries in the subjects studied. Nevertheless, because of the difficulties and shortcomings that have been noted, it cannot be said that the results in Table 1 establish a causal relationship between mental stress and acute caries in adults.

Further investigations will be undertaken, for it is considered to be highly probable that these two factors are associated, and, at least in some adults, that severe mental stress predisposes to the development of acute dental caries.

I thank Sir Arthur Amies and Prof. James Aitchison for their suggestions, Mr. P. D. Finch for advice on statistical matters, and the University of Melbourne Research Fund.

DIFFERENCES IN THE DEPOSITION AND PERSISTENCE OF PESTICIDES ON THE UPPER AND LOWER SURFACES OF LEAVES

By Dr. D. P. PIELOU, K. WILLIAMS and F. E. BRINTON

Entomology Laboratory, Canada Department of Agriculture, Summerland, B.C.

IN work on the deposition, persistence and effectiveness of pesticides on foliage in the field it is desirable to be able to determine the relative distribution of the chemicals on the upper and lower surfaces of leaves. The method devised by Rayner[1] allows the quantitative determination of certain fungicides on one side of a single leaf but, in the process, the deposit on the other side is destroyed.

An apparatus has now been devised by one of us (F. E. B.) which allows the separate and independent removal of certain pesticide deposits from the two surfaces of the same leaf (Fig. 1). Four compression springs (*CS*) hold together two square brass base plates (BP_1, BP_2). One of these plates is larger than the other. Each base plate has welded to it, and is penetrated by, a brass tube, 4 cm. in internal diameter, which acts as a solvent vessel (*SV*). These vessels can be closed at their outer ends by threaded brass caps (*C*) with polythene liners. In order to force apart the two halves of the apparatus, the larger base plate is placed on the support shoulder (*SS*) of a cradle. A lever device, with a forked arm (*FA*) which straddles the cap of the lower vessel, is then actuated so that the lower unit is forced down. A leaf (*L*) is inserted between the lips of the two vessels and the spring pressure is restored. The springs have been previously so adjusted that leaves will be in solvent-tight juxtaposition with the lips of the vessels but with pressure not so great as to perforate the foliage. A known amount of extraction solvent is placed in the upper vessel, which is then tightly capped. The apparatus is inverted and solvent is placed in the other vessel. The apparatus is then removed from the cradle and placed horizontally on a shaking machine.

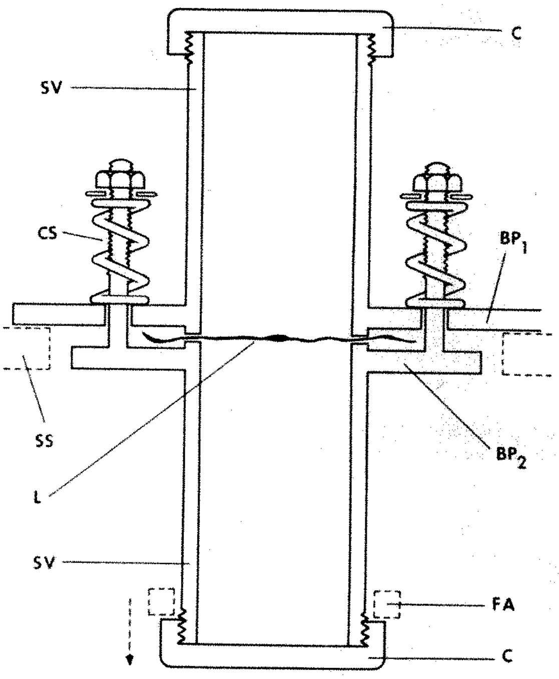

Fig. 1

Using 'Sevin' (1-naphthyl *N*-methylcarbamate) as an insecticide, and chloroform as an extraction solvent, agitation for 30 sec. was sufficient for recoveries of known deposits, from cherry and apple leaves, not significantly below those obtained by standard methods. In this period there was no translocation through the leaf by solvent action. This point was demonstrated by applying 'Sevin' to one surface of a leaf, placing chloroform in the vessel in contact with the opposite surface, and analysing for the presence of the insecticide in the solvent at intervals during agitation. With periods of up to 5 min. no transfer was detected. The method is speedy; extraction of 'Sevin' from both surfaces of 100 individual leaves can be carried out in 8 hr. A more detailed account of the construction and use of this apparatus and its effectiveness with other insecticides and other solvents will be published elsewhere[2].

Extensive use of this apparatus has shown that insecticides tend to be deposited more heavily on the lower surfaces of apple and cherry leaves than on the upper surface; and that weathering processes afterwards tend to accentuate this difference in distribution. For example, 'Sevin', 50 per cent wettable powder, was applied to cherry trees at the rate of 1 lb. per 100 imperial gallons until there was copious run-off from the leaves. Immediately after drying, 100 leaves were analysed; 75 of these had a higher deposit on the lower surface than on the upper. The mean deposit on the upper surface was 1·65 μgm./cm.^{2}; on the lower it was 2·38 μgm. or 1·44 times greater. Dwarf apple trees treated in the same way showed 130 leaves out of 144 as having heavier deposits on their undersides; the mean lower surface deposit was 1·84 times that of the upper. Essentially, similar results (ratio of lower to upper deposits, 1·75) were obtained with concentrate 'air-blast' spraying in which run-off of spray fluids does not occur. All these differences are statistically highly significant.

These findings cannot be explained in terms of the lower position of the operator with respect to the bulk of the tree because the small dwarf apple trees were sprayed as much from above as from below. It is highly likely, therefore, that the increased deposit is the outcome of some difference in structure between the two leaf surfaces. The difference may be related to the ultra-structure of wax on leaves that is revealed by electron microscopy of carbon replicas[3]. It is of interest to note the relative distribution on the two surfaces (but not the absolute amounts) was not significantly altered by the addition of 'Plyac', a film-forming surface-active agent of the polyethylene type (Allied Chemical Corporation, General Chemicals Division, New York, 6).

There was a clear indication that this difference was further enhanced with time. Deposit decline was somewhat more rapid on the upper surface even in the absence of rain. Thus, after 16 days the residual deposits on the lower surfaces of cherry leaves were 6·63 times those on the upper; the absolute values of both had, of course, fallen greatly from the initial values. It has been shown previously[4] that if rain, or water from overhead irrigation sprinklers, is present, deposits of 'Sevin' decline rapidly. This loss now appears to be primarily due to a reduction of deposit on the upper surfaces. Dwarf apple trees were irrigated, by overhead sprinklers, for 5 hr. with the equivalent of 2·1 in. of rain. Immediately before irrigation analysis showed that deposits on the upper and lower surfaces averaged 1·47 and 2·75 μgm./cm.^{2}, respectively; afterwards the values were 0·05 and 1·62 μgm./cm.^{2}, respectively.

The biological importance of these facts is obvious in the control of pests and diseases which predominate on one of the surfaces of a leaf, or for insects and mites that move freely from one side of a leaf to the other and show behaviour responses to insecticide deposits. Efforts are now being made to find adjuvants for pesticide formulations that will minimize the initial uneven distribution of deposits and reduce the rapid weathering from the upper surfaces of leaves.

OBSERVATION OF SEX DIFFERENTIATION IN *SORGHUM* BY USE OF INDUCED MALE-STERILE MUTANTS

By Dr. Z. BARABÁS

Agricultural Research Institute, Hungarian Academy of Sciences, Martonvásár

MALE sterility has been reported in many species of plants which is derived, almost without exception, from spontaneous mutations or crosses[1,2]. Those deriving from crosses may in the final issue likewise originate from spontaneous mutations. Induced male-sterile (*ms*) mutations have been so far reported, to my knowledge, only in the tomato[3], in which, however, the frequency of spontaneous *ms* mutants is also rather high[4]. Theoretically, the artificial *ms* induction is important from a genetic point of view of evolution and practically in the utilization of heterosis effects in plant breeding. In connexion with these problems, as a part of a larger programme[5], the following experiments were conducted.

During the past 30 years three genetically analysed cases of male sterility in *Sorghum* have been described[6–8]. During seven years 35,000–40,000 plants were examined yearly in our nursery, but completely pollen-sterile spontaneous individuals were never found. From these results it may be concluded that spontaneous mutants are very infrequent. The monogenic *ms* Day *SA* 380 (No. 1) and the cytoplasmic Combine Kafir *SA* 6062–1–8–4 (No. 2) described by

‡ 0–3 stigmas per ovary.
§ Sterile flowers in sectors on the panicle.

Stephens *et al.*[7,8], were the first *ms* forms of practical value. Mr. Stephens and Mr. Quinby kindly sent me three lines in 1955.

Homogeneous inbred strains of sorghum (*Sorghum vulgare* Pers. syn. *Sorghum* sect. *Sorghum* var. Rancher), which as a test object is endowed with a number of good qualities[9], were treated with doses of 10,000–35,000 r. X-rays in air-dried seed condition, and with 0·2–0·5 per cent aqueous solution of 0·1 per cent colchicine respectively injected in the scutellar node at the seedling stage. Colchicine was suggested, as gene-mutagen, by the results obtained by Franzke and Ross[10].

From the fertile Rancher strain three *ms* forms were obtained (Figs. 1–4, Table 1).

Male-sterile (*ms* 1645) Roentgen mutant attains about 60 per cent the height of the Rancher, its flowers are smaller, but its fertile sibs are of the same size. Its vitality is good, and seed setting complete.

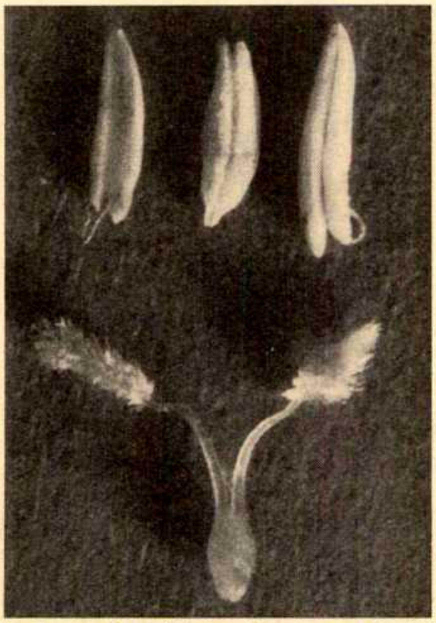

Fig. 1. Rancher, original variety, stamen and pistil

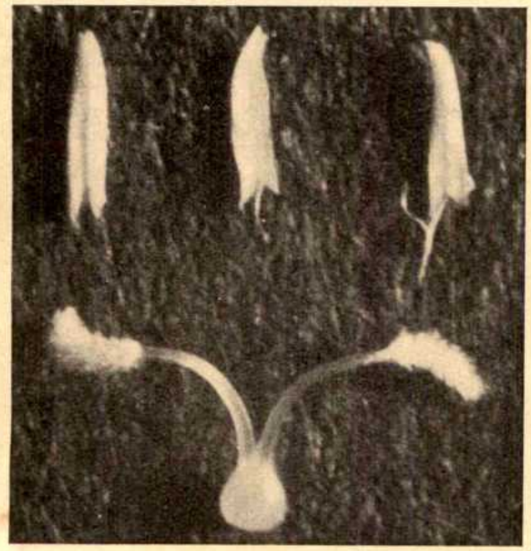

Fig. 2. Male-sterile mutant (*ms* 1645)

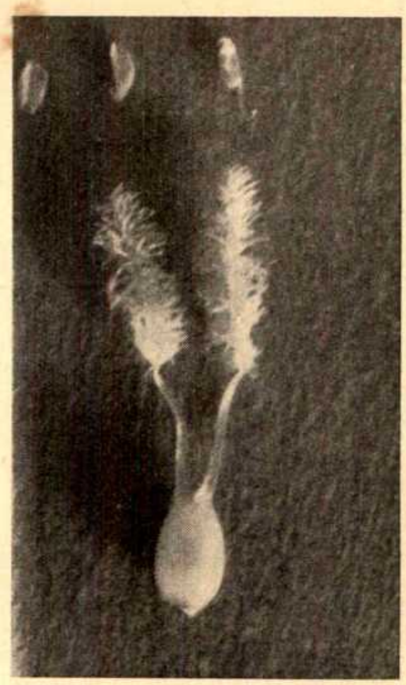

Fig. 3. Microanther mutant (*mth* 1916)

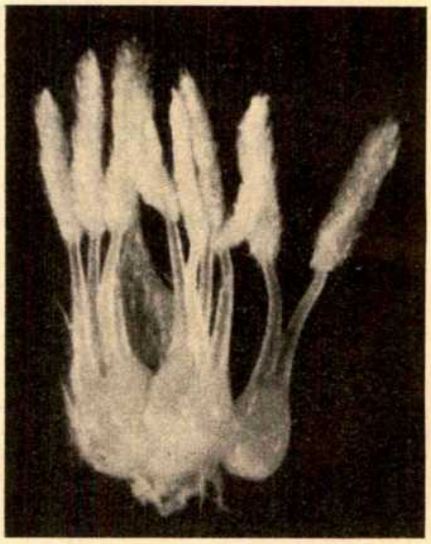

Fig. 4. Polygynæceous mutant (*pg* 2164)

Under short-day conditions it produces 1–2 per cent stainable pollen, but seed setting cannot be obtained from it. The constitution of the flower is similar to No. 2, but genetically different from it. This is shown also by the formation of F_2 and by the fact that F_1 is completely fertile when crossed with the counterpart of No. 2.

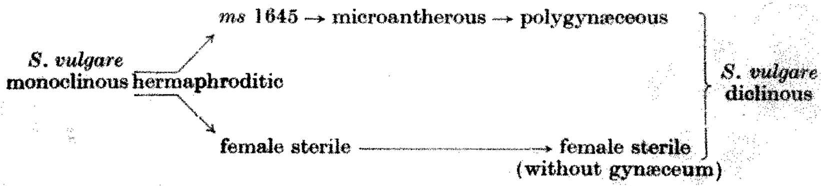
The microanther (*mth* 1916) colchicine mutant is a new form. No pollen is produced and its female sterility is also very high. The mutant is more viable, and it has more lateral shoots and panicles than the Rancher.

The polygynæceous (*pg* 2164) form has not appeared in *Sorghum*. Parallel mutants have been described in tobacco, barley, etc.[11]. In *pg* mutant up to four seeds for each flower occur. Multiplication is an important problem, since 10–12 pistils of the *pg* cannot be formed directly from three stamens. Contrary to Fig. 4 on some plants the partial transformation similarly occurs in a large number, making it difficult to ascertain the exact number of pistils. In some individuals, though stamens are often converted into an ovary, anthers may also occur, to a maximum of 6 per cent of the flowers, sometimes with fertile pollen ('intersex').

Frequently, the reduction of male sex is accompanied by the strengthening of the female sex. This is well expressed by the weight ratio obtained by measuring 35 sex organs, which were in fresh opened flowers, but did not yet fulfil their function. For example, in the fertile counterpart of No. 2 the gynæceum: anther ($G : A$) weight μgm. sex organ is 0·556 : 0·371; in the *ms* No. 2 it is 0·756 : 0·097, which means that pistil weight is higher in the *ms*. The $G : A$ ratio is about 1·5 : 1 and 8 : 1 respectively. The *ms* forms in Table 1 may be arranged on the basis of sex relations as follows: fertile Rancher → *ms* 1645 → *mth* → *pg*. The anther weight decreases roughly along exponential curve, while $G : A$ weight ratios are about $1 : 1 \rightarrow 2 : 1 \rightarrow 17 : 1 \rightarrow 170 > : 1$. Weight increase of the gynæceum is relative at first, then absolute. In the *pg* mutant the weight relation is about 170 > : 1 in the 'intersex', while increase to ∞ : 1 in the antherless mutant. The $G : A$ ratio establishes therefore the degree of sex reversal, and, to some extent, the sex index.

These steps, which are important from the morphological and evolutionary points of view, have a simple genetic background. The *ms* 1645 is not yet properly elucidated, but the male sterility may be simple recessive, as, for example, in case of No. 1. When back-crossed with the original form both the *mth* and *pg* show a segregation ratio of about 3 : 1 in the F_2. According to preliminary mitosis examinations of the types described, there is no evidence of division disturbances or chromosomal aberrations. Further investigations are needed, however.

An interesting completion of the *ms* series is the work of Casady *et al.*[12], reporting a female sterile form obtained by crosses also from hermaphroditic *Sorghum*. The female sterility is inherited by means of two gene-pairs. The female sex is present only in rudimentary form, but flowers without female organs have also occurred as a spontaneous mutation, but its maintenance was impossible for technical reasons[9]. On the basis of the foregoing, the sex differentiation develops in a similar way as was assumed in natural evolution by Correns (in ref. 13); a similar observation was made by Jones[14] in maize as spontaneous forms. In *Sorghum*, however, by means of these mutants, at least from the morphological point of view, intermediary steps could be examined likewise:



ms 1645 → microantherous → polygynæceous
S. vulgare monoclinous hermaphroditic
female sterile → female sterile (without gynæceum)
S. vulgare diclinous

The *pg* mutants, particularly the forms producing anthers too, are approaching the intersex postulated by Correns. A diclinous species was thus produced by way of mutations from a hermaphroditic (monoclinous) plant species. Some steps of sex differentiation occurring also in the natural evolution could be induced, therefore, artificially and observed *in statu nascendi*. Further investigations of these mutants will lead to a greater knowledge of sex inheritance in *Sorghum* and other hermaphroditic plants.

CRYSTAL STRUCTURE OF NaCd₂

By STEN SAMSON

Gates and Crellin Laboratories of Chemistry, California Institute of Technology, Pasadena

PHASE-diagram studies of the sodium–cadmium system have established the existence of a compound with the approximate composition $NaCd_2$; the several references can be found in Hansen[1]. Pauling[2,3] reported that $NaCd_2$ has a cubic structure with the edge of the smallest unit cube slightly more than 30 Å., and that this unit contains about 384 sodium atoms and 768 cadmium atoms. The space group was found to be O_h^7-$Fd3m$ (Pauling, private communication).

A structure determination of $NaCd_2$ has now been made by the stochastic method. The structure is in accord with an almost complete three-dimensional set of single-crystal X-ray data obtained with copper $K\alpha$ radiation.

Octahedral crystals of $NaCd_2$ were prepared by allowing sodium–cadmium alloys containing excess sodium to cool slowly. The excess of sodium was dissolved by treatment with absolute alcohol, leaving the crystals of the intermetallic compound. This is the method also used by Kurnakow and Kusnetzow[4]. Chemical analyses for both sodium and cadmium in five single-phase samples prepared as above gave compositions varying between $NaCd_{1.99}$ and $NaCd_{2.12}$; the analytical data reported by Kurnakow and Kusnetzow[4] correspond to $NaCd_{2.17}$. The densities measured on several single-crystal samples varied between $\rho = 5{\cdot}38$ gm./cm.^{3} and $\rho = 5{\cdot}63$ gm./cm.^{3}. Although this phase is probably of variable composition as indicated by these data the name '$NaCd_2$' will be retained.

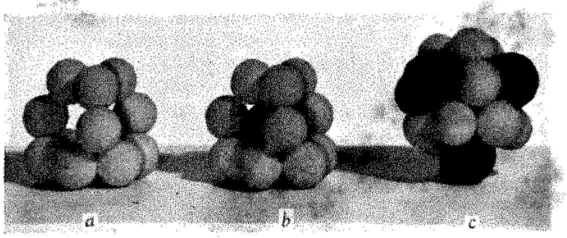

Fig. 1. *a*, *b*, The truncated tetrahedron; *c*, the Friauf polyhedron

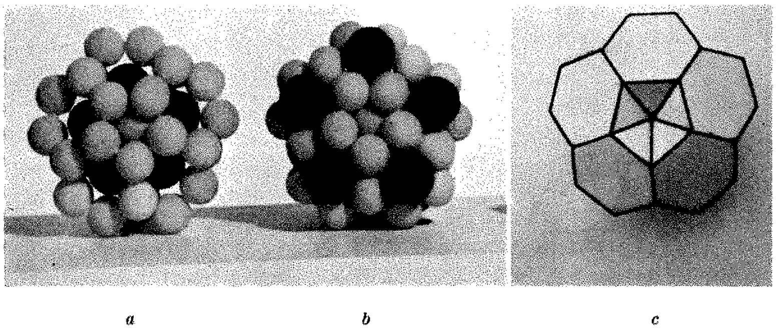

Fig. 2. *a*, Five truncated tetrahedra about a five-fold axis of symmetry; *b*, the F_5 polyhedron; *c*, a formal representation of the F_5 polyhedron. The atoms out from the centres of the hexagons are not indicated for the sake of perspicuity

The space group O_h^7-$Fd3m$ was confirmed, and the cube edge as measured for one crystal was found to be $a_0 = 30{\cdot}56$ Å.

On the basis of the experimental results given here, the unit cell contains between 1,120 and 1,190 atoms.

A structure to be tested by comparison of observed and calculated X-ray data was formulated with the assumption that many of the large atoms, the sodium atoms, have sixteen ligates, twelve cadmium atoms which are at the vertices of a truncated tetrahedron bounded by four hexagons and four triangles (Fig. 1*a*, *b*) and four sodium atoms which are located out from the centres of the hexagons of the truncated tetrahedron. The resulting polyhedron (Fig. 1*c*) in earlier papers[5,6], referred to as the Friauf polyhedron, is frequently observed in complex metallic structures containing atoms with metallic radii differing by about 15 per cent or more from one another. It was first observed in the Friauf phases $MgCu_2$ and $MgZn_2$ (refs. 7 and 8). Since the dihedral angles of a tetrahedron correspond to nearly one-fifth of a complete rotation, five Friauf polyhedra can be arranged about an approximate five-fold axis of symmetry in such a way that the five truncated tetrahedra have one edge in common on the five-fold axis, and each truncated tetrahedron shares two of its four hexagons with the two contiguous truncated tetrahedra (Fig. 2*a*). Such an aggregate of five Friauf polyhedra, which will be referred to as the F_5 polyhedron, represents the 47-atom complex shown in Fig. 2*b*. A formal representation of the F_5 polyhedron is given in Fig. 2*c*, in which the atoms out from the centres of the hexagons are not indicated for the sake of perspicuity. Six F_5 polyhedra are arranged about the vertices of an octahedron (Fig. 3). This octahedron is of T_d symmetry and hence only the (110) mirror planes are present. Each two F_5 polyhedra at the ends of the body diagonal of the octahedron are rotated 90° with respect to one another. The six F_5 polyhedra produce in their turn four Friauf polyhedra located at the vertices of a regular tetrahedron. These Friauf polyhedra are the dark ones shown in Fig. 3. The resulting aggregate consists of 34 Friauf polyhedra (6 × 5 + 4) and represents a 234-atom complex if the atoms out from the centres of the hexagons not indicated in Fig. 3 are included. Eight such 234-atom complexes can be fitted in the cubic unit in such a way that each complex shares atoms with four others (Fig. 4) such as to reduce the average number of atoms per complex to 144. The eight complexes thus contain 1,152 atoms. Eight more atoms have to be added, each one of them at the centre of a new Friauf polyhedron (F') formed by a set of six F_5 polyhedra. With the addition of thirty-two more atoms out from the centres of the triangles of eight such Friauf polyhedra (8 F'), the unit cell contains 1,192 atoms; and there are 280 Friauf polyhedra each about a central atom with ligancy 16 ($L16$). A closer examination reveals additionally 96 polyhedra of $L15$, 64 of $L14$, 128 of $L13$, and 624 polyhedra of $L12$ of which 528 are approximately regular icosahedra.

If each sodium atom is assumed to have ligancy 14, 15 or 16 and each cadmium atom ligancy 12, 13 or 14, and if of atoms with ligancy 14 there are as many sodium as there are cadmium, the unit-cell content corresponds to $Na_{408}Cd_{784}$ or $NaCd_{1{\cdot}92}$, and $\rho_{calc} = 5{\cdot}67$ gm./cm.^{3}.

With the atoms placed to fit this assumption, a fair agreement between observed and calculated structure factors was obtained. Several least-squares refinements resulted in an agreement index $R = 0{\cdot}15$ for the zero-layer reflexions, $R = 0{\cdot}21$ for the first 500 reflexions (*hk*0 through *hk*3), and $R = 0{\cdot}23$ for the almost complete three-dimensional set of reflexions; here $R = \Sigma|F_0 - F_c|/\Sigma|F_0|$.

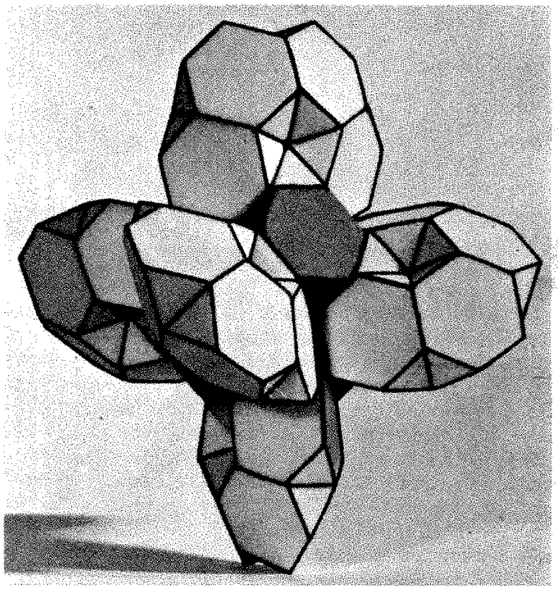

Fig. 3. The 234-atom complex formed by six F_5 polyhedra which are arranged around the vertices of an octahedron of T_d symmetry

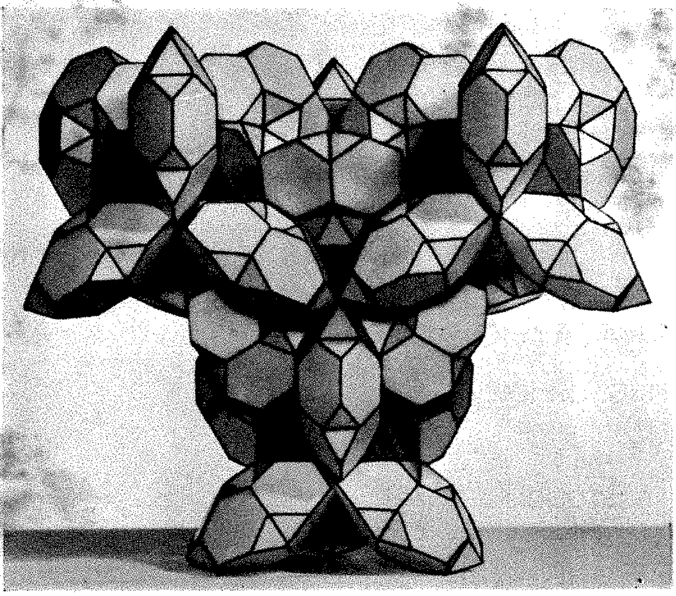

Fig. 4. Four 234-atom complexes arranged about one such complex. The four complexes are at the vertices of a regular tetrahedron

A Fourier section through the (011) plane was calculated with the use of all available data. Three peaks at assumed cadmium positions were found to correspond to approximately 0·5–0·75 of the reflecting power of cadmium, one sodium peak was higher than expected, and many of the other sodium peaks seemed somewhat lower than would correspond to complete occupancy. Least-squares calculations were then carried out with the inclusion of additional parameters that determine the approximate occupancy of the four positions just referred to, but the remaining sodium positions were taken to be completely occupied. Of the 1,480 reflexions used, 635 were too weak to be observed. At the present stage of the refinement 520 of the 'less than' reflexions are calculated lower than the minimum observable value of F, and 115 are still calculated somewhat too high. The agreement index, as defined here, is $R = 0{\cdot}17$ for all reflexions not including the 520 'less than' reflexions, and $R = 0{\cdot}13$ for the zero-layer reflexions, which are of considerably higher average intensity than those of the other layers.

The shortest and longest bond distances observed with the parameters obtained are Na–Na = 3·25–3·80 Å., Na–Cd = 3·12–3·80 Å. and Cd–Cd = 2·70–3·60 Å. The atomic positions, together with the as yet approximate positional parameters, are listed in Table 1. The least-squares calculations indicate that the disordered positions are occupied as follows: (1) 35 per cent Cd or 16 per cent Cd + 84 per cent Na in position $32e_4$, (2) 50 per cent Cd in position $32e_5$, (3) 70 per cent Cd or 62 per cent Cd + 38 per cent Na in position $96g_5$, and (4) 80 per cent Cd in position $96g_7$.

The crystals reacted with oxygen or moisture and gradually decomposed during X-ray photography. Therefore, several crystals had to be used to obtain the present results. The crystals were regular octahedra of diameter 0·20–0·27 mm., and absorption-correction factors[9] for spherical crystals of $\mu R \sim 7$ to 10 were applied to the measured intensities. Some systematic errors may accordingly have been introduced owing to inaccurate absorption corrections. It is also possible that some sodium was leached out of the crystals by the treatment with alcohol. It therefore did not seem justified to continue the refinement with the present data, although it became evident that the agreement factors could be considerably improved.

The work on $NaCd_2$ is now being continued with improved techniques for sample preparation and for the collection of intensity results. A detailed report on the structure and on the techniques used in determining the atomic positions will be published later.

A compound with structure apparently similar to that of $NaCd_2$ is βMg-Al (approximately Mg_2Al_3), which Perlitz[10,11] found by single-crystal X-ray studies to be cubic, space group O_h^7-$Fd3m$, with approximately 1,166 atoms per unit cube of edge $a_0 = 28{\cdot}22$ Å. Laves and Moeller[12] said that βMg-Al is isomorphous with Cu_4Cd_3; but the atomic positions were not known.

Preliminary work on these two phases has been carried out here in parallel with the above investigation. Crystals of βMg-Al were, unfortunately, always twinned, but the diffraction patterns are strikingly similar to those of $NaCd_2$. A single crystal of Cu_4Cd_3 has been isolated, and an almost complete set of intensity data has been obtained. The diffraction patterns of this phase differ drastically from those of $NaCd_2$ and βMg-Al. The probable space groups for Cu_4Cd_3 were found to be T_d^2, O^3 and O_h^5, and the cube edge to be $a_0 = 25{\cdot}83$ Å. This cubic unit contains approximately 1,116 atoms, according to the present experimental data.

The work on these two phases is also being continued. A detailed report will be published later.

I thank Prof. Linus Pauling for his interest and help. I also thank Prof. J. H. Sturdivant for useful discussions. Miss Brigitta Schönning carried out most of the preparative work and the X-ray photography as well as intensity measurements. Mr. Robert Ross contributed by checking and processing the intensity data.

OBSERVATION OF TRAPPED ELECTRONS IN POLYMETHACRYLIC ACID

By M. G. ORMEROD
Physics Branch
AND
L. G. STOODLEY
Radar and Telecommunications Branch, Royal Military College of Science, Shrivenham, Swindon

ELECTRON spin resonance is a useful tool in the study of the effect of additives on the radiation chemistry of solids. In particular, it has been used for elucidating the mechanisms of radiation protection in the solid state[1]. Another application is to use additives with special properties (for example, electron traps, radical scavengers) in order to help investigate the basic radiation chemical processes. In this article we report experiments of this type on polymethacrylic acid.

Our electron spin resonance work on polymethacrylic acid and its esters has led us to believe that the unpaired spins which are observed at 77° K. after irradiation at that temperature are trapped electrons[2]. In order to test this idea we decided to investigate the effect of some electron acceptors on the system, the chosen additives being pyromellitic dianhydride (PMDA) and tetracyanoethylene (TCNE).

The mixtures of 95 per cent polymethacrylic acid and 5 per cent additive were prepared by dissolving both compounds in ethanol and then driving off the solvent. The samples were sealed under vacuum in glass tubes and were irradiated at 77° K. with γ-rays from a 2 kilocurie cobalt-60 source (dose = 10^6 rads; dose-rate = 6×10^5 rads hr.$^{-1}$). They were examined in a conventional high-frequency (400 kc./s.) magnetic field modulation *X*-band spectrometer, all spectra being recorded as the first derivative of the absorption intensity as a function of variation in magnetic field. Unpaired spin concentrations were determined by numerical integration of the derivative curve and by comparison with a standard sample of α,α'-diphenyl β-picryl hydrazyl.

The electron spin resonance spectra obtained at 70° K. are shown in Fig. 1 and it can be seen that the additives had a marked effect on the nature of the radiation-induced spins. The spin concentration was not affected, the number of unpaired spins formed per 100 eV. of absorbed radiation (that is, *G*-value) being 1·5 in each case. The colour of the irradiated solid differed according to the additive, the colours being given in the caption.

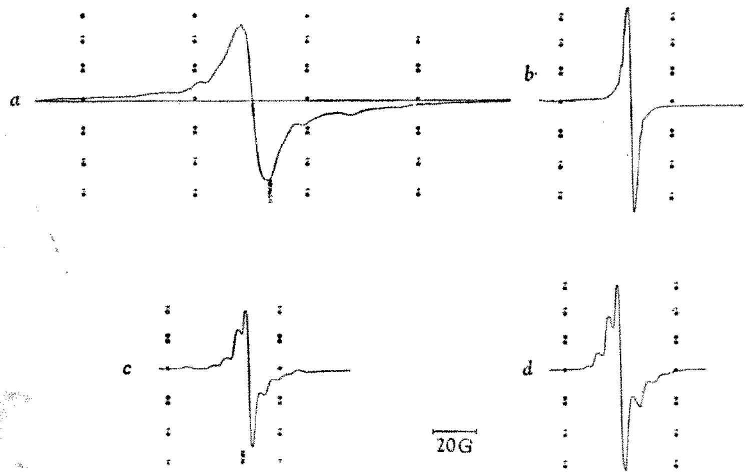

Fig. 1. Electron spin resonance spectra from some compounds recorded at 77° K. *a*, Polymethacrylic acid (brown) irradiated at 77° K.; *b*, polymethacrylic (red) plus 5 per cent PDMA irradiated at 77° K.; *c*, polymethacrylic acid (yellow) plus 5 per cent TCNE irradiated at 77° K.; *d*, the TCNE negative ion (yellow) in tetrahydrofuran. The colours in brackets refer to the colour of the solid at the time of recording the spectrum. The spectra have not been recorded at the same sensitivity

For the purpose of comparison we prepared the TCNE radical anion by reduction with sodium iodide in tetrahydrofuran solution. At room temperature this gave the known nine-line spectrum[3]. When cooled to 77° K. the resultant solid solution gave the spectrum of Fig. 1*d*, and although the anisotropic components of the hyperfine splittings are no longer averaged out, sufficient detail remains in the spectrum to show that it is identical with that obtained from the irradiated mixture of polymethacrylic acid and TCNE (Fig. 1*c*). Furthermore, both materials had the same yellow colour, showing that in the irradiated mixture we were observing the TCNE negative ion formed by the trapping of an electron which had been ejected by radiation from the polymethacrylic acid. In the pure polymer the electron is presumably trapped by the polymer itself. Similarly in the case of added

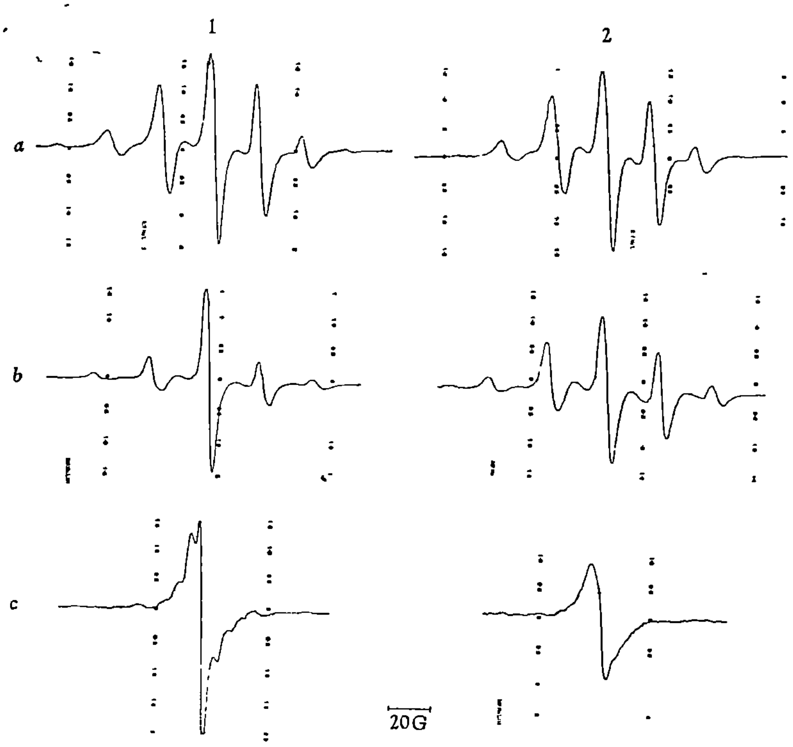

Fig 2 Electron spin resonance spectra recorded at room temperature from some compounds irradiated at 77° K (1) Immediately on warming to room temperature, (2) 24 hr later *a*, Polymethacrylic acid, *b*, polymethacrylic acid plus 5 per cent PDMA, *c*, polymethacrylic acid plus 5 per cent TCNE

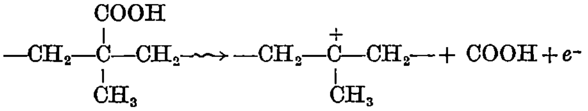
PMDA it is presumably the PMDA negative ion which is observed although the lack of detail in the spectrum (Fig 1*b*) would render unprofitable any attempt at positive identification

There was no evidence of the presence of a positive ion which should also have been formed This could be explained by a reaction of the type



$$-CH_2-\overset{COOH}{\underset{CH_3}{C}}-CH_2- \rightsquigarrow -CH_2-\overset{+}{\underset{CH_3}{C}}-CH_2- + COOH + e^-$$

COOH breaking down to give gases and gaseous radicals which diffuse through the polymer and react with one another The ion $-CH_2-\overset{+}{\underset{CH_3}{C}}-CH_2-$ does not have an unpaired electron and will not be observed by electron spin resonance

On warming to room temperature the colours of the samples faded—rapidly in the pure polymer but more slowly in the case of the other two materials At the same time the electron spin resonance spectrum changes (Fig 2) These simultaneous changes in electron spin resonance spectrum and colour indicate that it is the trapped electrons which colour the materials The TCNE negative ion decays with a half-life of about half an hour to leave an unidentifiable residue (Fig 2*c*) while the PMDA ion decays to leave the stable spectrum that is obtained from the pure polymer at room temperature, showing that this ion is reacting with the polymer

Previously in those polymers in which the radiation-induced unpaired spins have been positively identified it has been found that electrically neutral free radicals were present, for example, in polyethylene[4,5], polytetrafluorethylene[4], and polypropylene[6] These free radicals are the result of either a radiation-induced excitation or an ionization The ions that are formed are comparatively short-lived and react to give neutral free radicals before electron spin resonance spectra can be recorded. On the other hand, the final radiation damage in polymethacrylic acid is the result of the reactions of comparatively stable ions and excitation is only playing a minor part These stable ions, which are also observed in the esters of polymethacrylic and polyacrylic acids[2], are presumably associated with the —COOR groups

PLUTONIUM IN MAN AND HIS ENVIRONMENT

By PHILIP W. KREY, DONALD BOGEN and EUGENE FRENCH
Isotopes, Inc , Westwood, New Jersey

THE two plausible modes of entry of fall-out plutonium into man are ingestion and inhalation In studying ingestion, large discrimination factors were observed in going through the ecological cycle from soils to man[1] With such discrimination, it was concluded that incorporation via ingestion was quite unlikely[2]

Although inhalation as a mode of entry of fall-out plutonium into man was also considered to be insignificant[2], animal studies by Stannard[3] and Bair[4] indicated the accumulation of plutonium in the pulmonary lymph nodes on a per gram of tissue basis after prolonged inhalation exposure This is analogous to reports by medical authorities that radioactive colloidal gold concentrates in the lymph nodes when injected into patients for therapeutic or diagnostic purposes[5] Stannard concluded that the pulmonary lymph nodes may limit inhalation exposure under many conditions, and that calculation of maximum permissible doses on this basis may be required In investigations on man, Langham has demonstrated the accumulation of plutonium in the pulmonary lymph nodes of a plutonium operator who was exposed to a low-level chronic plutonium air-borne concentration for about six years In this investigation, the question of the critical organ following chronic inhalation exposure was raised again[6]

A second fact which prompted further investigation of inhalation as the mode of entry of fall-out plutonium into man was the estimates of the ground-level air concentrations of plutonium Baus[7] has reported that the average strontium-90 concentration for ground-level air in Washington, D C, during mid-1957 was about 1 5 DPM per 100 standard cubic metres This corresponds to about 0 2 per cent of the maximum permissible concentration in air of soluble plutonium-239 or -240 for continuous exposure of the general population with bone as the critical organ (A reduction to 1/10 of the maximum permissible concentration in air for occupational workers has been applied for the general population[9])

Eight air filter samples which were collected in Washington, D C, during the spring of 1959 were analysed in this laboratory for plutonium These samples represented a 24-hr collection period and were made available by Dr L B Lockhart, jun, of the U S Naval Research Laboratory The analyses showed an average ground-level air concentration of plutonium of 0 14 DPM/100 m^3 or about 1 per cent of maximum permissible concentration in air for the general population on the same basis as above This agrees with the British estimate of 0 2 DPM/100 m^3 for this same period[10] Based on these estimates and measurements, a cursory investigation of plutonium in human and animal tissue was undertaken

The α-spectra of the plutonium separated from several samples were determined using a thin cæsium iodide (thallium) crystal as a detector similar to the system described by Martinez and Senftle[11] and a 100-channel pulse height analyser The spectra of these samples showed pure plutonium-239 and/or -240 with no other α-contamination

Since the plutonium activities in the samples which were analysed were generally low, extreme caution was exercised to eliminate possible contamination of the sample during the analytical processing Reagent blanks were processed concurrently with samples to monitor the contamination-level if any existed In addition, lung tissue autopsied prior to 1945, made available through the courtesy of Colonel J M Blumberg, deputy director, Armed Forces Institute of Pathology, Washington 25, D C, was processed to represent ideal tissue blanks In all cases, the blank samples reflected no detectable α activity

Human tissue analyses The results of the human tissue analyses are given in Table 1 The errors represent one standard deviation of the counting error All samples were obtained in the New York metropolitan area The sample solution obtained from a 1959 lung sample was split and each aliquot analysed separately to reflect the reproducibility of the radiochemical procedure Analyses of other duplicate samples and standards in which the counting errors were minimal gave an average precision of better than ±5 per cent The composite organs in group I consisted of combined samples from six cadavers whose age at time of death was at least 70 years

The *National Bureau of Standards Handbook*[9] proposes a maximum annual dose of 15 rems for most individual organs of the body and 5 rems for the gonads or the whole body for occupational workers By applying a 1/10 reduction of this dose for the general population, the plutonium concentration in most individual organs can be converted to per cent of maximum permissible dose to that organ by multiplying the DPM plutonium/gm of tissue by a factor which converts the α-energy per disintegration a minute to rems per annum and dividing by the maximum permissible dose in rems per annum, that is

$$\frac{\text{DPM Pu}}{\text{gm of tissue}}\ \frac{\left(\frac{5\ 15\ \text{MeV}}{\text{Disint}} \times \frac{1\ 6 \times 10^{-6}\ \text{ergs}}{\text{MeV}} \times \frac{5\ 25 \times 10^{5}\ \text{min}}{\text{yr}} \times \frac{\text{rad}}{10^{2}\ \text{ergs /gm}} \times 1 \times 10^{1}\ \text{RBE}\right) \times 10^{2}}{1\ 5\ \text{rems/yr}} = \begin{array}{l}\text{per cent}\\ \text{of MPD}\\ \text{to organ}\end{array} \qquad (1)$$

$$\frac{\text{DPM Pu}}{\text{gm of tissue}} \times 28\ 8 = \text{per cent of MPD to organ} \qquad (2)$$

Since the maximum permissible dose (MPD) to the gonads is 1/3 that of most individual organs

$$\frac{\text{DPM Pu}}{\text{gm of gonads}} \times 86\ 4 = \text{per cent of MPD to gonads} \qquad (3)$$

Equations (2) and (3) were used to calculate the percentage of MPD, column 6 in Table 1

The most striking result obtained from the analyses of the human tissue is the high percentage of the maximum permissible dose delivered to the lungs, pulmonary lymph nodes and gonads by the plutonium deposited in these organs This is particularly emphasized by comparison with the average percentage of MPD delivered by strontium-90 to the adult skele-

Pork liver (average of 5 samples)	Autumn 1958 to Spring 1959	390	1 75 ± 0 73	4 48 ± 1 87	0 041 ± 0 017

ton Kulp[12] has reported that the average strontium-90 concentration in adult bone in 1959 for Western culture in the northern hemisphere was about 0 30 μμc /gm calcium or about 0 15 per cent of MPD The percentage of MPD for plutonium in lungs, pulmonary lymph nodes and gonads ranges from 1/3 to about ten times this percentage of strontium-90 MPD to the skeleton The gonad burden raises the question of genetic effects in addition to possible somatic effects

The distribution of total plutonium in the human organs measured supports the theory that inhalation is the significant mode of entry of fall-out plutonium into man In the composite organs of group 1, only one lung from each cadaver was analysed so that the activity (4 1 DPM) for the total lung sample should be doubled when comparing the plutonium content of the various organs It is clear that the total activity of plutonium in the lungs is about ten times greater than any other organ measured Further, the high activity per gram in the pulmonary lymph nodes (a factor of about 6 greater than the corresponding lungs) correlates with theories predicting that the plutonium deposited in the lungs will concentrate in the lymph system This suggests that the pulmonary lymph nodes may be the critical organ so far as plutonium inhalation is concerned It is interesting to note that the values of plutonium found in the lungs autopsied in the spring of 1959 agree with a predicted value of 1 DPM/gm calculated from the Harriman lung model of pulmonary deposition and the measured air concentrations[13]

Animal tissue analyses The results of the animal tissue analyses are given in Table 2 The samples comprising the steer No 1 organs were recovered from the same animal by making arrangements with a local slaughterhouse All other samples in Table 2 were purchased in supermarkets in the northern New Jersey area during the autumn of 1958 and the spring of 1959 In the stewing beef samples, numbers 3 and 4, the fluid was drained from the meat and each fraction analysed separately

The plutonium activities per gram of beef spleen, stewing beef and particularly the fluid extract from the stewing beef samples are relatively high Stewing beef samples are extracted from the shoulder of the animal in the vicinity of the thoracic duct Since these samples are all associated with the lymph system, there is an apparent correlation between high plutonium content and this system

The one lung of a steer analysed contained about the same quantity of plutonium per gram as did human lung Unfortunately, this lung was not recovered from the same animal as the No 1 group of samples Therefore, no definitive correlation between total plutonium burden and organ can be made to delineate the mode of entry of the plutonium into the animal

The general level of plutonium found in the other tissue in Table 2 reflects its somewhat ubiquitous nature The per cent of MPC for soluble plutonium with bone as the critical organ for ingestion of these meat products by the general population is also included in Table 2 These values were calculated by comparing the activity per gram of meat with the permissible activity per millilitre of drinking water Although the percentage approach 1 per cent in the spleen and stewing beef samples, the general levels are of no real significance so far as ingestion hazards of the total diet are concerned This has also been demonstrated by the plutonium analysis of several total diet samples which were collected by Consumers Union in their examination of strontium-90 during 1959 [14] The highest concentration of plutonium found in these samples (0 095 DPM/kgm) represents only 10^{-3} per cent of MPC for continuous ingestion by the general population

These data, particularly the results from the human tissue analyses, have shown that fall-out plutonium has entered the biosphere and man, and that inhalation is the main mode of entry into man In addition it appears that the pulmonary lymph nodes should be considered in the assignment of the critical organ so far as inhalation of plutonium is concerned The presence of plutonium in man as a result of nuclear weapons testing offers an opportunity to study the metabolism and translocation of this element within the body although the activity-levels encountered are low

INTEGRATED SURFACE EFFECTS OF ATMOSPHERIC POLLUTION

By E. N. LAWRENCE

Meteorological Office, Bracknell, Berkshire

SOME recent work[1] on the measurement of atmospheric sulphur dioxide by the commonly used lead dioxide (cylindrical) candle method[2] (with the louvred box at a height of 2 m. above ground) suggests that this or similar equipment may have a number of applications to atmospheric pollution problems in general. Results show that, under certain conditions, with a fairly sheltered site, the accumulation of sulphate on the cylinder (measured by P, the monthly mean daily number of mgm. of SO_3 collected by 100 cm.^{2} of 'batch A' lead dioxide) is related to V (the monthly mean daily concentration, vol. of SO_2 per 100 million vol. of air), by the formula

$$P = V(0\cdot 08u + 0\cdot 11) \qquad (1)$$

where u is the mean wind speed in m.p.h. When u is suitably large, P is proportional to u, for a given value of V, that is, $\Sigma P \propto \Sigma V u$, further evidence[1] from exposed moorland sites confirms this. These results are approximately what one might expect in an environment where temperature, humidity and rainfall have only second or lower order effects[2] on the total or 'integrated' surface effects of atmospheric pollution.

The dependence of the lead dioxide gauge on wind speed is confirmed by laboratory wind-tunnel data for a cylinder (with axis perpendicular to the wind direction). Powell and Griffiths[3] found that the rate of evaporation (E) therefrom is given by

$$E = 1\cdot 83 \times 10^{-6} u^{0\cdot 61}(p_w - p_a) \qquad (2)$$

where p_w and p_a are the vapour pressures of the saturated surface and the ambient air respectively, for a range of u from 0·5 to 3·0 m./sec. The basic data used to obtain equation (1) give P as an approximate power law of u with index of 0·5–0·6; the range of wind speed (monthly means) varied from 0·5 to 2·0 m.p.h. but, as stated above, the evidence[1] suggests that this index is nearer to unity for higher wind speeds (of the order of 5–10 m.p.h. at the height of 2 m.).

This lead dioxide equipment may well be of use in problems concerning the assimilation or absorption of a gaseous pollutant by a horizontal ground surface, although the laws governing the physical processes involved in the latter are different from those of a cylinder exposed in a polluted air stream. Following Sheppard[4], by replacing the eddy diffusivity by a term consisting of the sum of the molecular diffusivity in air of the gaseous pollutant (δ) plus $ku_* z$ where k is von Karman's constant, u_* the friction velocity and z the height above ground, but using concentrations instead of humidity mixing ratios, and considering the rate of deposition (D) instead of evaporation, we have

$$D = \frac{ku_*(\chi - \chi_0)}{\log ku_* z/\delta} \qquad z \gg \delta/ku_* \qquad (3)$$

where χ is the concentration at height z and χ_0 is the surface concentration. Allowing for atmospheric stability, by using a generalized form of k, we may write

$$D = \frac{ku_*(\chi - \chi_0)\, f(Ri)}{[\log u_* + \log kz\, f(Ri)/\delta]} \qquad z \gg \frac{\delta}{ku_*\, f(Ri)} \qquad (4)$$

where $f(Ri)$ is a function of the Richardson number (Ri). The appropriate form for $f(Ri)$ has been discussed by many authors[5–13]. The variety of forms quoted are all equivalent to

$$f(Ri) = 1 - \sigma Ri \qquad (5)$$

when Ri is small. Based on a number of studies, Blackwell[13] suggests that $\sigma = 7$ for $Ri > 0$ and $\sigma = 15$ for $Ri < 0$. For conditions near the ground, Ri tends to be small and $f(Ri)$ tends to unity, that is, under these conditions, there is a tendency for a neutral atmosphere; values of Ri near the ground are shown, for example, in the diagrams given by Priestley[8] and Pasquill[14]. Deposition, in practice, requires eddy exchange, which implies low Ri. Thus, over a long period (for example, a month), with σ of the order of 10 and Ri on average within 0·01 of zero, an error in the amount of deposition of within 10 per cent may well be achieved, on the assumption that $f(Ri)$ is unity. Further, if χ_0 is zero or small compared with χ and if z is such that the constant in the square brackets is substantially greater than $\log u_*$ (see, for example, Sutton[15]), equation (4) approximates to

$$D = \text{constant} \times (u_* \chi) \qquad (6)$$

Thus it would not be surprising if a practical empirical relation existed between the accumulation of sulphate by the standard lead dioxide cylinder and that by a horizontal ground surface (of given roughness), provided due allowance is made for any accumulation of sulphur dioxide, etc., on the latter, due to washout by rain (see, for example, Chamberlain[16]) or to scavenging processes in fog[17].

Results obtained by the lead dioxide gauge, or by any similar equipment, refer only to the point of measurement, where irregularities in topography give rise to variation in both wind and pollution concentration (but particularly the former) over very short distances. Measurements obtained, for example, on the perimeter of a forest-stand are not applicable to the well-sheltered interior. A close network of pollution gauges (preferably supported by run-of-wind gauges) is necessary for assessing the distribution of the total or integrated effect of wind-driven pollution. With only distant sources and the consequent more homogeneously polluted atmosphere, it is probable that wind is the dominant factor controlling the relative total effect between exposed sites (at least within a confined area and for a specific type of pollution) and that 'run-of-wind' data would provide such relative measures. Though maximum (surface) concentrations of pollution tend to occur with light winds under stable conditions, maximum 'integrated' effects may result from more turbulent conditions, and it may be useful to consider the degree of turbulence as well as the run-of-wind, in the interpolation of relative values

The magnitude of total surface accumulation of a pollutant by a suitable sensitive surface, such as the standard lead dioxide candle surface, may well be of greater practical application than that of the concentration of atmospheric pollution In polluted areas, it is certainly of paramount importance, for example, in problems relating to the use of ventilation in horticultural techniques or to pollution damage with non-streamlined building designs and to similar exposure problems in medicine, animal and crop husbandry and forestry—that is, in domains where atmospheric pollution effects are dependent on both atmospheric concentration and wind speed

The use of standard (artificial) surfaces as distinct from natural surfaces is not new to scientific recording techniques The painted surface of the Duvdevani dew-gauge[18], or the polystyrene block of the surface wetness recorder[19] for the estimation of leaf or plant surface wetness are examples In laboratory wind-tunnel work, various types of surface have been used to show surface flow direction or to distinguish between laminar and turbulent flow in boundary air-flow patterns These techniques (for example, refs 20–23) involve physical and chemical changes in the surface used, and depend on the visual observation of the degree of evaporation or sublimation, or, as in the 'contamination' techniques, the deposition of dust, etc , or the intensity of a chemically formed stain Surfaces are 'scoured' or 'swept', and reveal the degree of air-interchange, air-renewal or 'run-of-wind' close to the surface, near the boundary of zero wind velocity and the régime of molecular diffusion

ACID LEACHING OF THORIUM CARBIDE

By YASUICHI SASAKI, FUJIO ICHIKAWA, HISASHI IMAI and SHINOBU URUNO

Japan Atomic Energy Research Institute, Ibaraki-ken

RECENT developments of nuclear research has stimulated the study of new fuel materials such as carbides of uranium, plutonium and thorium These carbides have high melting-points and can be used in the reactor which is operated at high temperatures Furthermore, they show greater thermal conductivity than that of oxides

In the semi-homogeneous breeder reactor development programme, which has been planned in this Institute, the use of thorium carbide as a fertile material is considered

There are many problems in handling this material as a blanket fuel For example, protection from hydrolytic decomposition by moist atmosphere, physical and chemical actions in reactor circumstances and method of re-processing are the most essential

So far, Hyde *et al* [1] have carried out nitric acid leaching of compact carbide fuel composed of thorium and uranium

The existence of two compounds, ThC and ThC_2, is known, but experimental investigations were confined to the latter, as it was difficult to get the monocarbide in a single phase Compacted ThC_2 was prepared by the following method Powder of natural graphite and thoria was mixed, in the ratio of 1 part of thorium to 5 parts of carbon (by weight) The mixture of 1 gm was shaped into a compact 0 63 cm in diameter and 0 63 cm high under about 7,000 kgm /cm ^{2} in a briquetting machine The compact was converted into ThC_2 by heating at about 2,000° C for 3 hr in a vacuum Tammann furnace It was proved by X-ray diffraction analysis that the products were composed of ThC_2 and traces of graphite, and no ThO_2 or ThC was detected

The ThC_2 prepared was stored in a desiccator over phosphorus pentoxide, because ThC_2 reacts easily with atmospheric moisture to give gaseous hydrocarbons and $ThO_2(2H_2O)$

Acid Leaching of ThC_2 at Room Temperature

Acid leaching of the ThC_2 compact was examined using concentrations of acids, such as hydrochloric, sulphuric and nitric The degree of reaction was measured as the percentage of dissolved thorium to total thorium The method was as follows

A ThC_2 compact of about 1 gm was placed into 30 ml acid, then broken into pieces The solution was filtered after the reaction had proceeded overnight The residue was ignited in a platinum crucible at 900° C for 1 hr After graphite was oxidized into carbon dioxide, thorium was measured as thoria Meanwhile, the filtrate was dried and redissolved in 1 *N* hydrochloric acid, then thorium was precipitated as thorium oxalate by adding 10 ml of 10 per cent oxalic acid The precipitate was ignited after filtration, and the remaining thorium weighed as the dioxide

(i) *Hydrochloric acid leaching of ThC_2.* When the ThC_2 compact was put in a solution of hydrochloric acid, it disintegrated spontaneously and liberated gases with an acetylene-like odour. Almost all the ThC_2 was dissolved in this acid in a concentration-range of 0.5–12 *N* (Fig. 1).

(ii) *Sulphuric acid leaching of ThC_2.* In case of sulphuric acid leaching, ThC_2 dissolved with liberation of gases in the concentration range 0.5–1 *N*. But the solubility became gradually smaller with increasing concentration of this acid, and ThC_2 did not completely dissolve in the acid at a concentration above 10 *N* (Fig. 2). It is known that the solubility of $Th(SO_4)_2$ in sulphuric acid is lowered with increasing concentration of the acid. The leaching process of ThC_2 by sulphuric acid can be divided into two steps, namely, decomposition of ThC_2 and dissolving of $Th(SO_4)_2$ in sulphuric acid. The latter step is controlled by the solubility of $Th(SO_4)_2$ in the acid.

(iii) *Nitric acid leaching of ThC_2.* In the case of nitric acid leaching, an interesting result was obtained (Fig. 3). About 90 per cent of ThC_2 was decomposed in the concentration range 0.5–1 *N*, but the reaction grew less with increasing concentration of this acid.

In about 6 *N* nitric acid, the solubility of ThC_2 reached a minimum, then it gradually increased and recovered at higher concentration of the acid until up to a limit at about 50 per cent. Liberation of gaseous hydrocarbons was not observed at concentrations above 4 *N*, and charcoal-grey material appeared in colloidal form. It was observed that this material does not have a C—H bond as indicated by the results obtained from infra-red spectroscopic analysis and that the greater part of it precipitates in an aggregate form at about *p*H 1. When this material is heated in air, it burns out easily. The X-ray diffraction analysis proved that the insoluble material is ThC_2 and not thoria.

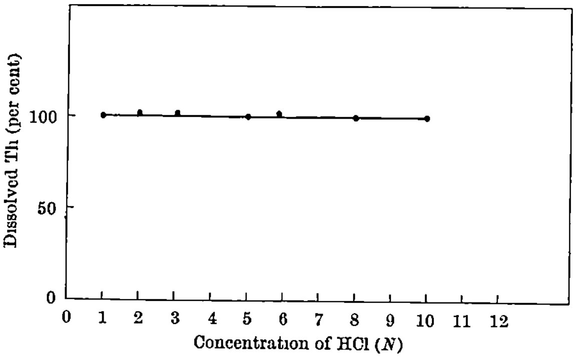

Fig. 1. Dissolving of ThC_2 in hydrochloric acid at room temperature (24 hr.)

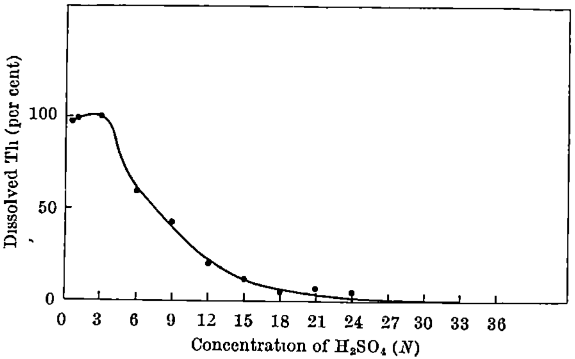

Fig. 2. Dissolving of ThC_2 in sulphuric acid at room temperature

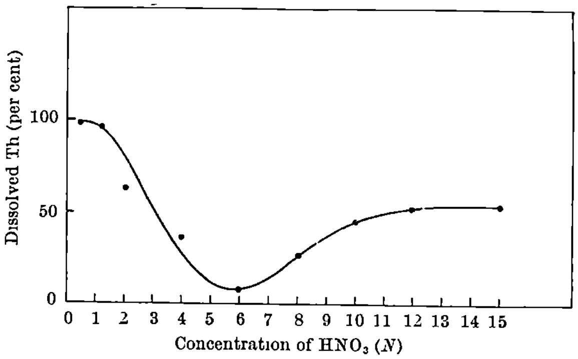

Fig. 3. Dissolving of ThC_2 in nitric acid at room temperature

From the experimental results described, this charcoal-grey material might be colloidal carbon rather than organic material. It is considered that ThC_2 is soluble in dilute nitric acid as well as in hydrochloric acid, while in the case of concentrated nitric acid, gaseous hydrocarbon does not generate and free carbon is isolated because of increased oxidation produced by increasing concentration of the acid. The isolated carbon becomes colloidal carbon and/or dispersed in solution.

A clear explanation cannot be advanced for the redissolving of ThC_2 in nitric acid at concentrations above 6 *N*, but it might be speculated tentatively that the dissolving reaction would be effected by the dissolving-rate of intermediate compounds of thorium which are formed on decomposition of ThC_2. As a tentative explanation for this phenomenon, the following reaction is postulated:

$$ThC_2 + 4HNO_3 = Th(NO_3)_4 + (CH_2)_n$$

$$ThC_2 + 4HNO_3 = ThO_2(2H_2O) + 4NO_2 + 2C$$

$$ThO_2(2H_2O) + 4HNO_3 = Th(NO_3)_4 + 4H_2O$$

Acid Leaching of ThC_2 at 80° C

Experiments were carried out also at 80° C. Leaching was continued for 7 hr. The experiments were conducted only at concentrations of 8 *N* and 12 *N* for nitric and sulphuric acids, respectively, because the results at room temperature showed the minimum solubility at these concentrations.

(i) *Sulphuric acid leaching of ThC_2 at 80° C.* For comparison with the results of leaching at the higher temperature, leaching at room temperature was also carried out under the same conditions. The solubility of ThC_2 at room temperature was 1.8 per cent in 12 *N* sulphuric acid, whereas at 80° C it was 6.1 per cent. The effect of temperature on the solubility of ThC_2 is small, and this means that the principal factor for sulphuric acid leaching is the solubility of $Th(SO_4)_4$ in sulphuric acid.

(ii) *Nitric acid leaching of ThC_2 at 80° C.* In the case of 8 *N* nitric acid, the solubility of ThC_2 at room temperature was 19 per cent and rose to 99 per cent at 80° C.

Table 1. EFFECT OF TEMPERATURE ON DISSOLVING OF ThC_2 IN 8 *N* NITRIC ACID AND 12 *N* SULPHURIC ACID

Acid	Leaching temp.	Leaching time (hr.)	Dissolved Th (per cent)
H_2SO_4	At room temp.	7	1.8
	At 80° C	7	6.1
HNO_3	At room temp.	7	19
	At 80° C	7	99

The effect of temperature on ThC_2 dissolution into 8 *N* nitric acid and 12 *N* of H_2SO_4 are shown (Table 1).

GEOPHYSICS

Space Density of Dust in the Stratosphere

THE Smithsonian meteoritic dust programme has included a number of aerosol collections made by various aircraft in different altitude ranges These include collections in the range 40,000–48,000 ft by a *B*-52, roughly 60,000 ft by a *U*-2, and 51,000–87,000 ft by an *F*-104*A* The purpose of these collections was to obtain samples of meteoritic material, both so that we could estimate the rate of accretion by the Earth of extraterrestrial matter and analyse it chemically

Our first step has been to investigate the space density of dust particles of all types as a function of height and of time The space density was calculated simply by dividing the total number of particles of a certain size-range by the volume encountered by the opening of the collector, taking into account the efficiency of the collector Wind-tunnel tests provide us with a set of values for the efficiency of the collector under various conditions of velocity and altitude

Table 1 MEAN SPACE DENSITIES

Aircraft	Height (ft)	Mean space densities (particles > 3μ diam /m ^{3})
B-52	40,000–48,000	4,000
U-2	60,000	2,800
F-104*A*	51,000–87,000	1,000

The true space densities for atmospheric particles are given in Table 1 The values for the lower altitude flights were computed from the counts of particles of all types, from which background counts as determined from unexposed (but flown) filters were subtracted The original counts were for particles with mean dimensions greater than 6μ These we transformed into counts for particles larger than 3μ by means of the known size distribution[1] To derive the space densities tabulated, we then divided the counts by the effective volume of air encountered The tabulated results clearly show a decrease of particle space density with altitude

Meteoritic spherules Small, spherical particles that strongly resembled, both in appearance[1] and chemical composition[2], meteoritic droplets such as are found surrounding falls of larger meteorites[3] were discovered on five *B*-52 filters Because of recent wind tunnel tests, the previous calculations of the rate of fall of such particles to the surface must be revised upward The correct space density of these particles is approximately $3/\text{m}^3$ at 45,000 ft If as Stokes's law would indicate, they fall at the rate of approximately 1 cm /sec from this altitude, the expected rate of fall on the Earth's surface is 0 3 spherule/cm ^{2}/day This is not significantly different from the actually observed rate of fall of such particles in the Arctic[4], which is approximately one spherule/cm ^{2}/day We believe that the essential agreement of these greatly different experiments is good evidence that our conclusions about the meteoritic origin of the particles are correct Furthermore, the present results indicate that approximately 2×10^8 kgm of this kind of meteoritic material fall to the Earth a year (using standard assumptions[2]) This is not inconsistent with our previous value of 5×10^8 kgm /yr (ref 4) and is in excellent agreement with the results of Crozier[5] and Thiel and Schmidt[6], who collected spherules from land and ice sediments, respectively

Equatorial Micropulsations and Ionospheric Disturbance Currents

THE early evening maximum of occurrence of regular geomagnetic pulsations, *pc*, of period 20–30 sec , was first detected on the Earth current recordings obtained at Legon, Ghana, during the International Geophysical Year[1], but more recently, Cardus[2] has confirmed that the occurrence of evening *pc* is also a feature of micropulsational activity at other equatorial stations No satisfactory hypothesis has yet been proposed to explain why this type of geomagnetic activity is a day-time phenomenon at all mid-latitude stations, with a maximum of occurrence and amplitude at approximately mid-day, while, in the region of the magnetic equator, there is an evening maximum of both occurrence and amplitude, with lesser maxima at mid-day and early morning[3] Several attempts have, however, been made to relate the occurrence of *pc* pulsations with ionospheric disturbances, and interesting results have recently been obtained by Campbell and Matsushita[4], who suggest that the onset of micropulsation storms is associated with an increase in ionospheric disturbance, and by Hope[5], who puts forward the proposal that the movement pattern of the ionospheric disturbance currents produces maximum geomagnetic activity at different times of the day at high, middle and low latitudes

So far as the Legon micropulsation results are concerned, it has been considered for some time that the evening maximum of *pc* activity must be associated in some way with the other known equatorial disturbance phenomena, but previous attempts at correlation of *pc* occurrence at Legon with the ionospheric parameters from a neighbouring station have proved unfruitful However, following the ideas suggested by Campbell, Matsushita and Hope, the correlation between *pc* activity and the disturbance daily variation, S_D, has recently been determined and, in this case, the results are encouraging

Using the continuous recordings of the Earth current potential gradients at Legon between April 1958 and March 1959, the disturbance daily variation of the Earth currents has been determined, and in Fig 1 the resultant amplitudes of the S_D potential gradients for each hour are given The daily variations of (*a*) the

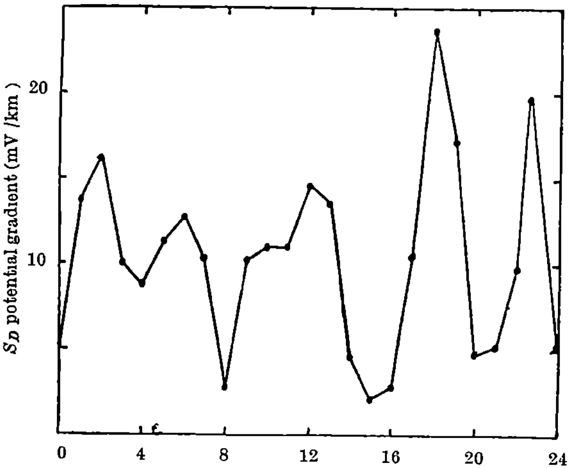

Fig 1 The annual mean S_D variation of Earth current potential gradients at Legon

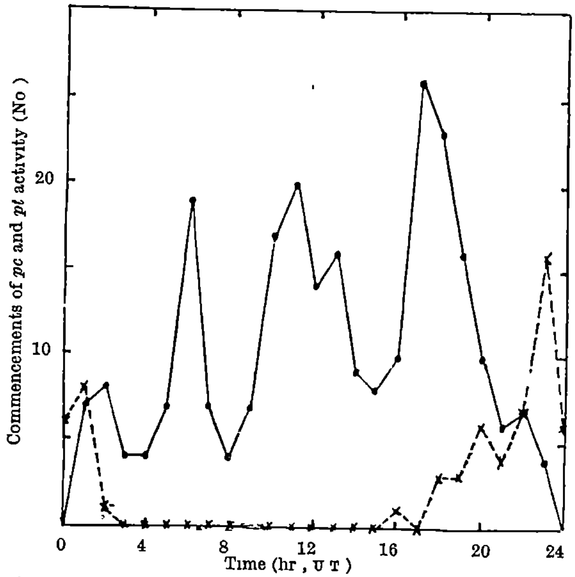

Fig 2 The daily variation of the number of commencements of *pc* and *pt* activity during one year at Legon ——, *pc* pulsations, – – – –, *pt* pulsations

frequency of occurrence of *pc* pulsations, of amplitude greater than some arbitrary fixed level, and (*b*) the number of commencements of such pulsational activity during each hour were also obtained from the same Earth current records Both variations (*a*) and (*b*) were found to agree reasonably well with the S_D variation, the agreement being particularly good for variation (*b*), which is given in Fig 2 Examination of Figs 1 and 2 suggests that there is a close correspondence between the probability of onset of *pc* pulsational activity and the magnitude of the disturbance daily variation of the Earth current potential gradient at the same station The correlation coefficient between these two variables has been determined for the time-interval 3–21 hr and found to be 0 6 As this value is highly significant, it may be concluded that the most probable times of onset of geomagnetic activity of type *pc* coincide with times of S_D maxima, that is, 6 hr, 12 hr and 18 hr On the other hand, as the correspondence for the night maxima of S_D is not so good, it is suggested that the night maxima are related to some other form of pulsational activity For example, *pt* pulsational activity is known to have a maximum of occurrence frequency at approximately 22 hr, the daily variation of the number of occurrences of *pt* at Legon during a 12-month period being represented by the dotted line in Fig 2 From a comparison of Figs 1 and 2 for the 6-hr period around midnight, it seems reasonable to conclude that the S_D peaks at 2 hr and 22 hr are associated with *pt* activity

In considering the S_D variation of Fig 1, it must be remembered that the Earth current values reflect the rate of change of the magnetic field variations and hence also the rate of change of the currents in the ionosphere Investigations of the S_D variation of the Earth currents at Legon thus indicate that the disturbance currents in the equatorial ionosphere experience their most rapid change at approximately 18 hr, and that at 2 hr, 6 hr, 12 hr and 22 hr, there are additional large changes in the ionospheric current strength It may also be noted that the S_D Earth current flow at Legon has been found to be more or less uni-directional, but with the mid-day and early evening current flowing from north to south and the night-time current flowing in the reverse direction[6]. There is thus a tendency for the north-to-south current flow to be associated predominantly with *pc* activity and the south to north flow with *pt* activity

The correlation between the commencement of *pc* activity and increase in ionospheric disturbance currents is thus well established at this equatorial station and agrees well with the auroral zone studies of Campbell and Matsushita and also with the comments made by Hope[7] on the Earth current S_D variation at Kakioka However, the estimation of the extent to which the movement of the S_D current may account for the mid-day maximum of *pc* activity at mid-latitude stations and the evening maximum at the equator requires an examination of similar data from a wide network of stations

PHYSICS

Core Kinetics of Fission Reactors

Our theoretical and experimental work on the core kinetics[1] of water-moderated fission reactors has been continued

The autocorrelation function of reactivity fluctuations in a reactor operating at low power has been computed from a record of the fluctuations (Fig 1) The experimental results support the simplified kinetic theory For a reactor in which delayed neutrons are neglected, this predicts a power spectral density $W(f)$ of the form

$$W(f) = \frac{A}{1 + \omega^2 \left(\frac{l}{\beta}\right)^2} \qquad (1)$$

and an autocorrelation function $\psi_{aa}(\tau)$ of the form

$$\bar{\psi}_{aa}(\tau) = \frac{A}{4\left(\frac{l}{\beta}\right)} e^{-\frac{\beta|\tau|}{l}} \qquad (2)$$

where A is a constant, l is the mean effective prompt neutron lifetime, β is the delayed neutron fraction, ω is the angular velocity and τ is the correlation time The departure of the function from the exponential form indicates the presence of higher frequency components in the core fluctuation The apparent periodicity is inherently linked with the nuclear events which take place within the core

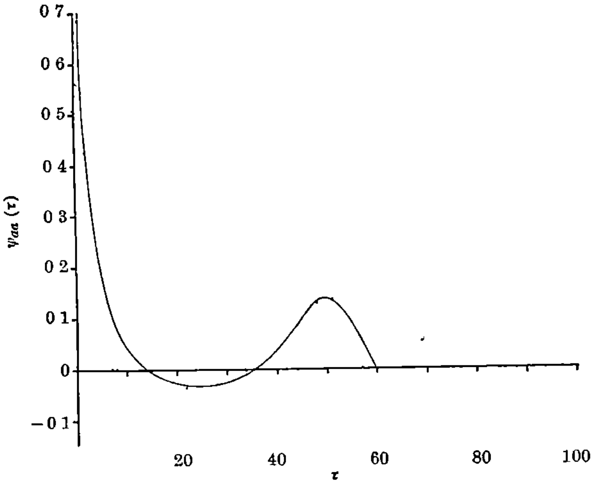

Fig 1 Autocorrelation function of reactor fluctuation (τ = sec 10^{-2})

In Fig 2 is shown the proposed experimental arrangement for the study of core kinetic fluctuations by means of cross-correlation Correlations may be measured between nuclear and non-nuclear parameters and system interactions may be studied without any major disturbance to normal reactor operating conditions Provided that the assumptions concerning system linearity are valid, the following integral relationships now hold for the reactor core being examined

$$\psi_b(t) = \int_0^\infty \psi_a(t-\tau)h(\tau)\mathrm{d}\tau \qquad (3)$$

$$\psi_b(p) = n(p)\psi_a(p) \qquad (4)$$

$$\bar{\psi}_{aa}(\tau) \approx W(f)\delta(\tau) \qquad (5)$$

$$\bar{\psi}_{ab}(\tau) = \int_0^\infty \bar{\psi}_{aa}(\lambda_M-\tau)h(\tau)\mathrm{d}\tau \qquad (6)$$

where, in this case, $W(f)$ is the power spectral density of ψ_a, $\delta(\tau)$ is a delta function, $\bar{\psi}_{ab}(\tau)$ is the cross-correlation function, $h(t)$ is the reactor impulse response, $n(p)$ is the reactor transfer function and p is the Laplace transform variable The driving function $\psi_a(t)$ is designed to introduce a pseudo-random fluctuation into the reactor core Its autocorrelation function is, approximately, a delta function

This investigation, together with measurements concerned with the propagation of periodic and pulsed signals in a reactor core and the variance of a reactor control channel, is being carried out in collaboration with the Research Reactor Group at Harwell[2]

The objective of these experiments is to develop new techniques for (1) The measurement of reactor system parameters (2) The characterization of nuclear reactor types by means of such functions as their 'impulse response' and the systematic monitoring of these characteristics for incipient instability.

Half-Lives of Carbon-10 and Neon-19

THE half-lives of carbon-10 and neon-19 are not well known Only two measurements of the half-life of carbon-10 have been reported, the first of 8 8 sec [1] was in error due to an impurity in the boron powder used; the second, due to Sherr *et al* [2], was 19 1 ± 0 8 sec In the case of neon-19, values ranging from 17 4 ± 0 2 sec [3] up to 20 3 ± 0 5 sec have been reported[4]

During the course of experiments on the reactions ^{10}B(p,n)^{10}C and ^{19}F(p,n)^{19}Ne it became possible to measure the carbon-10 and neon-19 half-lives for β^+ decay by using an *R I D L* 400-channel pulse height analyser (model 34–12) in its time analyser (multichannel scaler) mode of operation As a timing unit a 100-kc /sec crystal oscillator, having a stability better than 1 part in 10^5, was scaled down to provide a pulse which advanced the analyser address every 2 sec

For measuring the half-life of carbon-10 a 200–250 μgm /cm ^{2} self-supporting boron-10 target (we are indebted to Mr F A Howe and associates at the U K Atomic Weapons Research Establishment, who made this target) was irradiated for 60 sec with 0 1 μamp of 7 5 MeV protons from the Canberra tandem accelerator, and the decay of the induced activity followed for 290 sec , that is, about 15 half-lives The β^+ decay of carbon-10 goes 98 4 per cent to the first excited state of boron-10 (0 717 MeV excitation) and 1 65 ± 0 2 per cent to the second excited state[5] Since the decay of carbon-10 is uniquely identified by the 0 717 MeV line, it was measured using a 3 in × 3 in NaI(Tl) crystal spectrometer feeding a single channel analyser with the window set over the relevant γ-ray photopeak By following the decay of counts in the window it was possible to obtain single component decay curves on a constant, low background To check that other activities were not affecting the results, several determinations were made by following the decay of the coincidence counting-rate from a coincidence unit of 0 2 μsec resolving time Two 3 in × 3 in NaI(Tl) crystals, placed on opposite sides of, and $\frac{1}{2}$ in from, the target, were used, one feeding a single channel analyser with a window over the 0 511 MeV photopeak and the other a similar analyser with a window over the 0 717 MeV photopeak By following the decay for many half-lives it was shown that in both methods the backgrounds were constant, and accurate subtractions could be made (Fig 1)

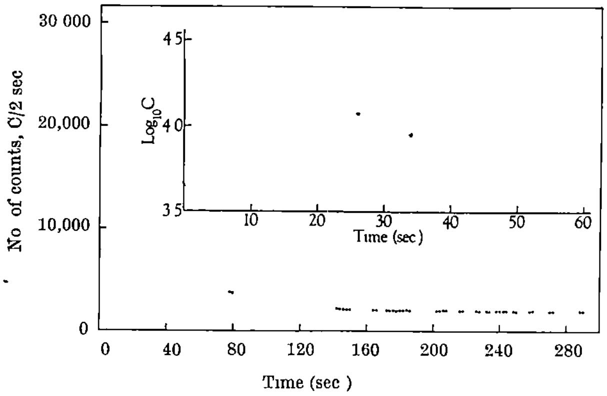

Fig 1 A typical decay curve for carbon-10, together with a logarithmic plot of the data after subtraction of the background This curve consists of the sum of a number of runs, in each of which counting loss and gain-change effects are negligible

A logarithmic plot of the results was made, and a straight line fitted to it by a statistically weighted least squares treatment, the slope of the straight line so obtained gave the half-life and its root mean square error directly Table 1 gives the results for the half-life of carbon-10 obtained for several independent determinations

Table 1

Half-life values for ^{10}C (sec)	Half-life values for ^{19}Ne (sec)
19 37 ± 0 12	17 40 ± 0 13
19 55 ± 0 12	17 48 ± 0 13
19 62 ± 0 12	17 29 ± 0 13
19 63 ± 0 15	17 32 ± 0 13
19 33 ± 0 12	17 64 ± 0 13
19 40 ± 0 12	

For measuring the half-life of neon-19 the fluorine-19 target was obtained by vacuum evaporation of manganous fluoride on to a 300 μgm /cm ^{2} gold foil, and was irradiated with 0 1 μamp of protons at approximately 4 8 MeV The decay of neon-19 goes 100 per cent to the ground-state of fluorine-19 (ref 4), and hence the decay was followed with the single channel analyser window covering the 0 511 MeV annihilation γ-ray photopeak For the check, the decay of coincidences between the annihilation quanta was followed This did not exclude from the measurement other positron activities present on the target However, the linearity of the logarithmic plots indicated that the effect of any such impurities was negligible The data were analysed as before, and the values obtained are given in Table 1

From these data the half-lives and their standard errors were determined as

$$\tau\,(^{10}\text{C}) = 19\ 48 \pm 0\ 05 \text{ sec}$$
$$\tau\,(^{19}\text{Ne}) = 17\ 43 \pm 0\ 06 \text{ sec}$$

Temperature Coefficient of Electrical Resistance of High-Purity Rhodium

The temperature coefficient of electrical resistance between 0° C and 100° C , $\frac{(R_{100} - R_0)}{100\,R_0}$, is an accepted criterion of the purity of platinum Very high-purity platinum, such as is used in the manufacture of resistance thermometers and thermocouples, has a temperature coefficient approaching 0 003927, and this represents the purest platinum commercially available For rhodium, the other element used in standard thermocouples, the temperature coefficient of electrical resistance is not at present used for assessment of purity, but measurements made by us indicate that it might be a useful criterion for this metal also The highest value recorded in the literature[1] for the temperature coefficient of electrical resistance, between 0° C and 100° C , for high-purity rhodium is 0 00457

Recently, wires made from two samples of rhodium powder produced by the Mond Acton Refinery were found to have temperature coefficients considerably greater than that value, and the purity of these samples has been determined by mass-spectrographic analysis (determined by Dr T A Davies, Birmingham Research Laboratory, International Nickel Co (Mond), Ltd) and correlated with temperature coefficient One of the powder samples was of normal commercial grade, selected because spectrographic analysis indicated a low impurity content, the second sample, which had been specially prepared, was known, from neutron-activation analysis[2], to have a low iridium content

The resistivities were determined at the ice and steam points, on resistance thermometers wound from wires 0 0068 in in diameter, and having a resistance of about 1 5 ohms at 0° C The wire was fabricated from the rhodium powder by vacuum-sintering hydrostatically pressed powder compacts at 1,500° C , and rotary swaging at 1,100°–1,200° C to rod 0 125 in in diameter The rod was hot-drawn through tungsten-carbide wire dies to 0 015 in diameter, and then cold-drawn to the final size The values of the temperature coefficient of electrical resistance and the mass-spectrographic analyses of

Table 2

Iridium content of rhodium (p p m atomic)

	Neutron activation analysis determined on powder	Mass-spectrographic analysis determined on wire
Specially purified rhodium	2	3 5
Commercial purity rhodium	92	30

the wires are given in Table 1 The iridium contents of the samples determined by mass-spectrographic analysis and neutron-activation analysis, are compared in Table 2

The mass-spectrographic analyses do not give an absolute determination of the impurities present since standards were not available, but the relative levels of any element in the two samples are reliable

The lower impurity content of the specially purified rhodium compared with that of the commercially purified material is clearly shown It is believed that the lower contents of iridium, ruthenium and iron in particular contribute to the improvement of the temperature coefficient

High calcium, aluminium and silicon contents, as found in these samples, have been noticed also in high-purity platinum[3], they are possibly due to segregated particles of oxide, from which preferential sparking occurs during mass-spectrographic examination The iron contents of the rhodium wires are also comparable with those found in high-purity platinum, and it is considered that the iron is not due to any contamination during hot-working procedures used on the rhodium

GEOLOGY

Aragonitic Fossils in the Lower Carboniferous of Scotland

ALTHOUGH many invertebrates form skeletons partly or wholly of aragonite, this normally inverts to calcite within a geologically negligible period of time, a few tens of thousands of years at the most[1] Indeed, more than 50 per cent of the aragonite laid down by some of the marine invertebrates studied by Lowenstam[2] inverted to calcite within a year As the geothermal gradient lies completely within the stability field of calcite it has been maintained that aragonite within buried sediments could exist only in peculiar local conditions of high hydrostatic pressure and moderate temperature[3] Aragonite in rocks of a respectable age may therefore be presumed rare, and any record of such an occurrence is of interest both because of the problems posed by the preservation of this metastable mineral and the desirability of obtaining unaltered shells for palæo-ecological studies

Initially in this department finely preserved nacreous shell material of ammonites from the Cretaceous Speeton and Gault clays was found to consist wholly of aragonite This form of preservation, not uncommon in some Tertiary and younger Mesozoic rocks, was afterwards recognized in a small quantity of material from the Palæozoic, where it is very rare, and it is with this that the present communication is concerned

The fossils occur in three specimens of shale, in the collection of H M Geological Survey in Edinburgh, from the Cot Castle (or Basket) Shell-bed in the Lower Carboniferous, Upper Oil Shale Group, zone P_1 of Currie[4] *M* 2132^L and *M* 2135^L come from a depth of 263 ft in the No 1 bore, Baads Mine, and *E* 8010 from about 150 ft depth in the Fraser No 1 shaft, West Calder, West Lothian Fragments of the shells of several molluscs, of either nacreous or chalky appearance, were subjected to X-ray analysis using the following technique

Samples were obtained by breaking or scraping material from the shells into an agate mortar and grinding by hand with an agate pestle under acetone No inversion of calcite to aragonite occurs under these conditions Smear mounts on glass slides were prepared and the samples tested on a Phillips *PW* 1050 X-ray goniometer, using automatic chart recorder, filtered copper radiation, slits 1° and 0 1 mm , scan-rate 1° 2θ per min , range scanned 10°–50° 2θ Approximate *d*-spacings and relative intensities were obtained from these charts and compared with data cards in the A S T M powder data file

Aragonite and calcite were the only phases giving prominent reflexions

The nacreous shells of a goniatite (*Beyrichoceratoides*) and an orthocone nautiloid were found to consist wholly of aragonite while corresponding shells of microgranular chalky appearance consist of mixtures of variable amounts of aragonite and calcite The chalky shell of a zygopleurid gastropod was also found to consist of both minerals It appears, therefore, that breakdown of the nacreous shells has been accompanied by partial inversion to calcite, though possibly in the case of the gastropod the original shell consisted of a mixture of the two minerals, as in some modern forms It is worthy of note that in recent aragonitic shells the fine structure tends to break down before any inversion occurs[1]

According to Mr R B Wilson, preservation of nacreous or chalky shells is very exceptional in the Scottish Carboniferous Usually the shells have been dissolved away or replaced by calcite or pyrite It is not clear why aragonite should have been preserved in this instance It may be partly a consequence of the impermeable character of the shale matrix of the Cot Castle Shell-bed in particular and the Oil Shale Group in general, together with the absence of surface weathering The shale of the matrix seems, however, to lack exceptional features In thin section it is seen to be homogeneous and unlaminated, with scattered pyrite granules and rare fragments of detrital quartz An analysis by the Geochemical Department of the Grant Institute indicated some 26 per cent of calcium carbonate, 2 9 per cent of organic carbon and 2 5 per cent of sulphur The mineral composition of carbonate, which consists in part of small shell fragments, was not determined

This seems to be the oldest recorded occurrence of aragonite The only other certain Palæozoic occurrence known to us was reported by Stehli[5], who records aragonitic molluscs in Upper Carboniferous (Pennsylvanian) shales and asphalt of Oklahoma and Kentucky

We thank Mr R B Wilson for making available the fossils and providing useful information

Inclusions in Garnets

RECENT developments in structural mapping in the Dalradian rocks of Scotland have led to the re-interpretation of regional metamorphism and recognition of its phase-by-phase development[1-5] In this respect, textural studies have proved particularly useful in so far as relict textures are preserved as inclusions within porphyroblasts, thus permitting a recognition of fabrics[6], which in the rock as a whole, owing to subsequent recrystallization, have disappeared In the middle-grade zones of regional metamorphism of Dalradian rocks, garnet porphyroblasts are particularly abundant, and their inclusions can be grouped into the pre-porphyroblast, the syn-porphyroblast and the post-porphyroblast

The pre-porphyroblast (residual) inclusions can be divided into two types (*a*) dimensionally strongly orientated inclusions of mainly quartz, feldspar, calcite and ores which trend at an angle to the foliation outside the porphyroblast, (*b*) dimensionally weakly orientated inclusions of mainly quartz, feldspar and calcite showing triple junctions and having the trend which parallels or is continuous with the external fabric In hundreds of examples considered by us, the former inclusions have a grain-size much smaller than the grain-size of the fabric outside the porphyroblast, while the latter inclusions have a grain-size comparable to that of the minerals outside the porphyroblasts It is suggested that in the former case the garnet with its internal fabric belongs to an episode of metamorphism earlier than the deformation which has caused the rotation of the garnet with respect to the external fabric In the latter case, however, the garnet has grown under static conditions and belongs to essentially the post-tectonic episode of crystallization and recrystallization responsible for the partial obliteration of the dimensional preferred orientation of the external fabric Identical geometric criteria can be applied to other porphyroblasts, including feldspars, kyanite, staurolite and chloritoid The degree of preservation of residual inclusion may depend on complexities of growth and dissolution, but it must be emphasized that their existence is independent of the existence of the porphyroblast

The syn-porphyroblast (cogenetic) inclusions are those which have been generated either in the matrix surrounding a growing porphyroblast or at the growing surface of such a porphyroblast The former type includes quartz, feldspar ores, sphene, etc, while the latter are of graphite, ores and sphene The pattern of the former type of inclusions is conditioned partly by concurrent deformation or crystallization and partly by the velocity of growth of the porphyroblast For example, if a porphyroblast is growing at the same time as the rock is subjected to deformation, *S*- or *Z*-shaped trends of inclusions will be observed within the porphyroblast. Clearly the tightness of the loops of the *S* will depend on the velocity of the growth of the porphyroblast with respect to deformation The pattern of the inclusions generated at the growing surfaces of porphyroblasts will depend on the shape of the crystals concerned In larger garnets, in particular, such patterns can be used to trace changes of the growing faces The experimental work of Stober[7] may be relevant to the growth of such inclusions When, however, Galwey and Jones[8] claim that we have advanced the view[1] that, contrary to Stober, "the high rate of crystallization results in the development of inclusions", they are misinterpreting our ideas, since we were dealing with residual inclusions in the process of dissolution and not cogenetic inclusions in a stage of growth

The post-porphyroblast inclusions in garnets can be divided into two groups those which have no obvious systematic relationship to the garnets and merely occupy cracks in it and those which show systematic crystal orientation with respect to garnets and are in the main micas and feldspars, which in certain cases replace the garnets entirely These inclusions, which have no bearing on relations of garnet growth to deformation, will be described elsewhere by one of us (N R), and have been called the penetration inclusions

Since there are numerous examples of combinations of these effects, in so far as concentric zones of garnets can show different inclusions, it is not surprising that Galwey and Jones find a wide variety of inclusions which they list without explanation. The position is further complicated by the fact that the most common post-tectonic garnets in the Dalradian of Scotland overgrow various textural patterns in the rock, resulting in preservation of complex inclusion trends which may be difficult to interpret on geometric relationships alone. Consequently in tracing the relationships of inclusions to garnets in addition to purely qualitative microscopic examination, the nature of deformation and recrystallization was estimated by petrofabric examination of the quartz inclusions and their comparison with the quartz of the matrix. This method enabled us to prove that features of preferred optical orientation still preserved in certain pre-porphyroblast types of inclusions cannot be discovered in the surrounding matrix. This more than anything else convinced us that the hypothetical pore solutions *A* and *B*, dendritic crystallization, etc., invoked by Galwey and Jones, and for which there is no evidence, are not factors of importance. In any event, our interpretations are based not just on garnets, but on all other minerals as well. We agree with Galwey and Jones that very great care must be exercised in interpreting inclusion fabrics. Indeed, the temptation to resolve difficulties by recourse to conjectural chemical reactions is not easy to resist.

MINERALOGY

Measurement of the Surface Conductivity of Mineral Grains

During an investigation into the principles underlying the electrostatic separation of minerals in a corona-discharge, roll-type separator, it was found necessary to measure the surface conductivity of individual mineral grains.

The apparatus used consisted essentially of two stainless steel rollers, each 0·5 in. in diameter and 2 in. long[1], mounted in polytetrafluoroethylene end-plates on a metal base (Fig. 1). One of the rollers was set eccentrically on its bearing stub so that the distance between the rollers could be set at half the diameter of the grain being measured, the minimum grain size being in practice about 72 B.S. mesh (211μ). The roller assembly, with an antimicrophonic lead fitted to each roller, was set in an earthed brass box fitted with inlet and outlet tubes which enabled air at a controlled relative humidity to be passed through the box. Humidity control was effected by a closed-circuit system, consisting of diaphragm pump, sintered glass bubbler containing a saturated solution of electrolyte[2], glass-wool spray trap, stainless steel gauze ion trap, rotameter, and the electrically screened brass box containing the rollers. The minimum amount of insulating material was used in the construction of the apparatus because it was found that static charges tended to build up on the insulators, giving false readings.

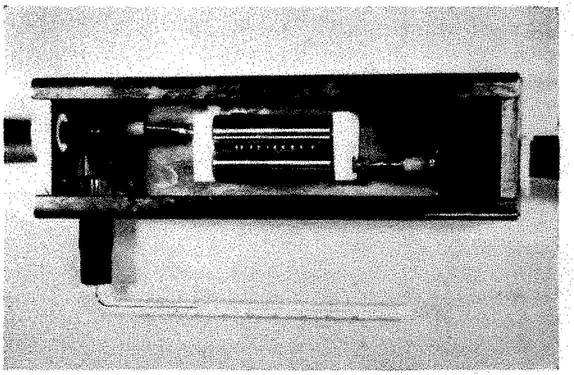

Fig. 1. Apparatus for measuring the surface conductivity of mineral grains

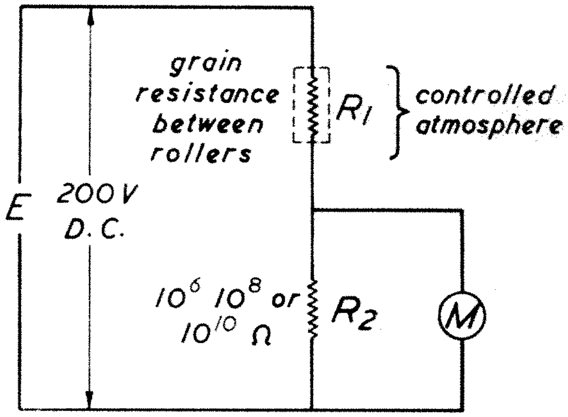

Fig. 2. Circuit for measuring surface resistance of mineral grains. *V*, Voltage; R_1, grains; R_2, resistance box; *M*, Vibron electrometer

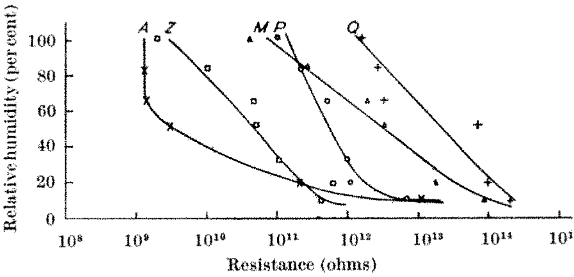

Fig. 3. Resistance of 10 grains as a function of relative humidity. *A*, Albite; *Z*, zircon; *M*, monazite; *P*, pyrochlore; *Q*, quartz

The equivalent electrical circuit used is shown in Fig. 2. The potential across the mineral grains was fixed at 200 V. d.c. (*E*), as this value gave reproducible results and also approximates to the potential difference existing across the grain when a charge has been acquired from the ion current in the corona discharge separator.

R_1 is the resistance of the mineral grains on the rollers, R_2 is a standard electrometer resistance box of 10^6, 10^8 or 10^{10} ohms, which in practice was always at least two orders of magnitude less than R_1. *M* is a vibrating condenser electrometer measuring the potential difference (V) across R_2. From the circuit constant and the measured value of V, $R_1 = ER_2/V$, since $R_1 \gg R_2$.

Mineral grains were closely sized, washed in distilled water, dried at 110° C., and conditioned at the selected relative humidity for at least 6 hr. Ten grains were placed between the rollers, the system was given at least 10 min. to settle, and the resistance was then measured. Ten measurements were normally made at each relative humidity value, namely, at 10, 20, 33, 52, 66, 84 and 100 per cent. A fresh set of grains was used for every measurement to obviate errors caused by ion transport or polarization in the mineral grain[3].

When plotted, the curves of log resistance against per cent relative humidity were linear or gently curved. The results were found to be reproducible to within half an order. This apparently low reproducibility is due to the fact that the property being measured is the resistance of an insulator, at best a somewhat dubious parameter. Typical results are shown in Fig. 3, each point on the graph representing the mean of ten readings. Our curves differ from those obtained by Kakovsky and Revnivtsev in that only in a few cases are they strictly linear, and that some minerals attain a low limiting value of resistance due to saturation of the mineral surface by a water film at high relative humidities.

Cell Dimensions and Interatomic Forces in Layer Lattice Silicates

The factors which control the sheet dimensions of the layer lattice silicates have been carefully re-examined recently[1], both from a structural point of view[2], and by the methods of multiple regression analysis[3]. This has led to a new, more explicit geometrical model[4] for the octahedral layers of these minerals, and thence to a detailed study of the balance of forces which must be involved. The results of the latter are outlined here.

Megaw, Kempster and Radoslovich[5] have attempted to understand the felspar structure, anorthite, by treating the network of bonds and bond-angles rather as a problem in statics, comparable with the design of bridge trusses. The same kind of approach is profitable for the layer lattice silicates, with the following general conclusions.

(1) The primary control of all three dimensions, *a*, *b* and *c*, is vested in the octahedral layer. In this layer the highly charged cations are only partly shielded electrostatically from each other across the shared octahedral edges. There is a strong mutual repulsion which is balanced by the limit of stretching of the cation–anion bonds, and the limit of compression towards each other of pairs of anions in these shortened shared edges (in accordance with Pauling's rules).

(2) Other factors exert control at a secondary level, or in extreme cases in an over-riding fashion. These factors include: (*a*) interlayer cation-surface oxygen bonds; (*b*) net surface charge (for example, cation exchange capacity effects); (*c*) net octahedral layer charge; (*d*) polarization of anions, particularly surface hydroxyls; (*e*) interlayer hydrogen bonding; (*f*) surface hydroxyl–hydroxyl bonding; (*g*) limitations of tetrahedral deformation, governed by bond-lengths and anion–anion compression. I believe that detailed examples of each may be found in various layer silicate structures already determined accurately.

(3) For several quite accurate structures the reported minor variations in bond-lengths—both within one structure, and between structures—appear to be consistent with these general concepts. The variations apparently may be 'explained' by treating these minerals as essentially ionic structures and then considering the effects on the bonds of small but known variations in effective electrostatic valency. Very similar arguments have been used by other authors in discussing several rather unrelated inorganic structures determined with notable precision recently.

(4) If these ideas are substantially correct then they: will allow much better prediction of trial structures of layer lattice silicates; should give convincing explanations for observed composition limits for the naturally occurring minerals[6]; cause considerable rethinking about the forces governing the morphology of kaolins and serpentines[7]; and have real bearing on the relative stability under weathering, and on the observed polymorphism, of the micas.

I thank Dr. K. Norrish, Division of Soils, and Mr. L. G. Veitch, Division of Mathematical Statistics, C.S.I.R.O., for their assistance.

ELECTRICAL ENGINEERING

Electrode Phenomena in Magnetohydrodynamic Power Generation

Recently[1] Maycock, Noé and Swift-Hook have described some results obtained in a magnetohydrodynamic power generation experiment involving the use of a rocket motor and a kerosene–oxygen fuel mixture seeded with potassium. Both carbon and water-cooled copper electrodes were used, with the unexpected result in the latter case that high conductivities could be obtained despite the low electrode surface temperature of about 400° C. A possible explanation was suggested in terms of a thin carbon layer found on the electrode surface at the end of the experiment. It was thought that this layer might provide thermionic emission of electrons into the gas stream and thus permit 'electronic' conductivity to apply to this situation.

Working with cold electrodes in air plasmas produced by an electrically driven shock tube[2], we have observed similar high values of conductivity, but in a situation in which no carbon is present.

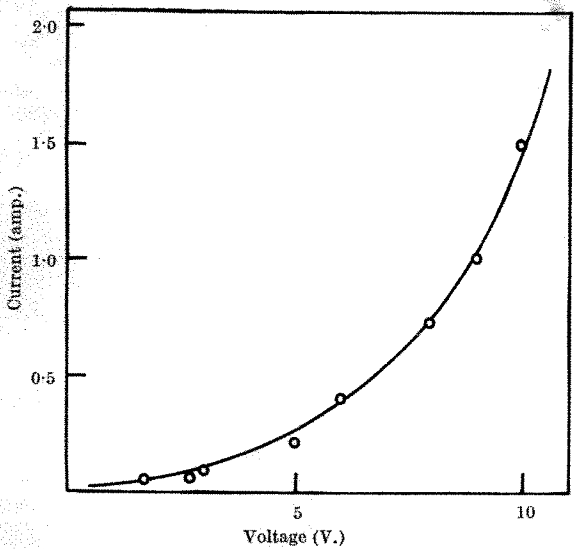

Fig. 1. Current-voltage characteristic for an air plasma produced in an electrically driven shock tube. Parallel disk probes, 0·5 cm. diam., 1·4 cm. apart. Initial air pressure = 1 mm. mercury; shock speed = Mach 12 (equilibrium temperature, 4,200° K. approx.)

Typical results for the current flowing between two parallel disk electrodes as a function of applied voltage are shown in Fig. 1. The resistance between the probes at high current densities (of the order of 50 amp./cm.[2]) is found to correspond to the 'electronic' conductivity of the air plasma, after allowing for fringing effects. However, at lower current densities the resistance is very much higher and indicates the presence of sheath voltage drops at the electrodes. Similar results have been obtained for various electrode materials (for example, nickel, brass, and gold).

The physical processes capable of providing continuity of 'electronic' current at the cathode at high current densities are believed to be complex and may involve several different phenomena. An analogous situation exists at the cathode of the cold-cathode arc, for which many hypotheses have been proposed[3]. That favoured by us for the present situation involves collision ionization in a thin layer of gas adjacent to the cathode when the field strength (and thus current density) is high enough. At still higher field strengths this region extends to fill the whole space between the electrodes, but does so without the sharp transition normally separating the 'dark' discharge region from a glow discharge and spark breakdown. Typical oscilloscope records of current are shown in Fig. 2, with multiple exposures superimposed to show the different effects. At low field strengths the current pulse lasts only for the duration of the shock-heated gas between the probes (approximately 10 μsec.); but at higher field strengths the plasma can remain highly conductive for periods long after the initial hot gas has passed the probes. The current finally extinguishes at different times from shot to shot presumably owing to variable diffusion and recombination processes.

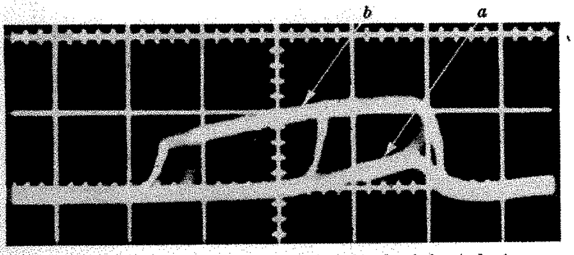

Fig. 2. Current flow between probes in shock-heated air as a function of time. (Time reads from right to left. Scales: 0·5 amp. per division; 10 μsec. per division.) Initial air pressure = 0·2 mm. mercury; shock speed = Mach 9 (equilibrium temperature = 3,000° K. approx.). *a*, Low field strengths; *b*, high field strengths, with breakdown

Thus the interesting possibility is raised of using not only cooled electrodes but also the enhanced conductivity of secondary ionization processes for magnetohydrodynamic power generation. Under high-temperature conditions the electric field strengths required to create breakdown are very small compared to normal cold gas situations. This proposition has been discussed by Westendorp, Bishop, Hurwitz, Goldman and Ben Daniel[4], who also present some interesting results for non-thermal ionization in helium plasmas seeded with cæsium. Similar breakdown in high-temperature gases at low field strengths is being observed in steady-state experiments being carried out here with argon between graphite electrodes. In the latter case high equilibrium conductivities are also being measured (approximately 10^8 times the theoretical argon conductivity for the same temperature and pressure), suggesting that impurities from the graphite electrodes (commercial grades) may in fact be seeding the gas. Further experiments with very pure graphite (reactor-grade *A*) are being carried out to establish whether this or some other mechanism is the explanation for the high conductivity.

We acknowledge the financial support for the energy-conversion project at the University of Sydney provided by the Electrical Research Board and the Australian Institute of Nuclear Science and Engineering, which is making possible this experimental programme.

CHEMICAL ENGINEERING

Detonation in Ammonium Nitrate

It has been appreciated for many years[1-5] that ammonium nitrate, even when free from combustible material, can detonate. This is not surprising, since the products of decomposition must be entirely gaseous and have substantially less energy of formation than the original substance. For example, if the nitrogen is not oxidized, the energy released at constant volume, with water in the vapour phase, is 380 cal./gm. or 8·7 kcal. per mole of gas. This is, of course, rather low compared with typical values for explosives, which lie in the range 20–50 kcal./mole gas. The temperatures and pressures reached in the detonation wave will therefore also be relatively low, and one might expect the substance to detonate with difficulty and only under good confinement. This is found to be so. For normal material at densities around 1 gm./cm.[3], cartridge diameters of many inches or heavy metal tubes are necessary[6,7], and even then the measured speeds are much lower than the maximum values calculated for products $N_2 + 2H_2O + \frac{1}{2}O_2$. This has led some authors[8] to conclude that an equilibrium involving oxides of nitrogen is more appropriate, and that the release of energy is of order 230 cal./gm.

It is well known that reduction in the loading density of an explosive makes propagation easier, and this can be explained in a general way by the increase in compressibility, so that, although the overall energy yield is no greater, more extreme conditions arise in the wave-front. Velocities greater than 2 km./s. have been reported[9] for an ammonium nitrate at 0·65–0·7 gm./cm.^{3} in steel tubes, particularly at elevated temperatures.

We have recently made some measurements on material the physical form of which results in an unusually low bulk density, 0·52 gm./cm.^{3}. This was loaded into light-weight cellulose acetate or cardboard tubes, and initiated by primers of Blasting Gelatine. Its behaviour was recorded by placing lead plates under the charge, and the detonation velocity measured by the Dautriche method at the larger cartridge diameters and with a streak camera at the smaller. The direct streak record was supplemented by a back-lit silhouette record because of the low level of light given out.

Steady propagation was recorded down to 2-in. diameter over at least a 2-ft. length of charge, and at $1\frac{1}{2}$-in. diameter over a 9-in. length. At 1-in. diameter the wave died out quickly. The velocities were as follows:

Charge diameter (in.)	$1\frac{1}{2}$	2	3	$5\frac{1}{2}$	$7\frac{3}{4}$
Detonation velocity (km./s.)	1·40	1·55	1·78, 1·95	2·05	2·23

When these velocities are plotted against reciprocal charge diameter, they are fitted quite well by a straight line, and extrapolation to infinite diameter indicates a limiting speed of 2·37 km./s. and a reaction time of around 7μs. Calculations by the method of ref. 6 with assumed products $N_2 + 2H_2O + \frac{1}{2}O_2$ predict the following maximum speeds:

Density (gm./cm.^{3})	0·5	0·6	0·7	0·8	0·9	1·0
Detonation velocity (km./s.)	2·36	2·56	2·76	2·98	3·22	3·48

Interpolation gives 2·40 km./s. at 0·52 gm./cm.^{3}. It seems, therefore, that this analysis describes correctly the behaviour of ammonium nitrate as a detonating explosive, at least at low charge density. Certainly, the observed speeds are too high to be reconciled with a release of energy of 230 cal./gm., which would imply a limiting velocity of only 1·87 km./s.

Bubbles in Fluidized Beds

GAS fluidized beds are characterized by 'bubbles' which rise through them, modifying the gas flow path and moving solid particles. Bubbles are largely responsible for solids mixing, for high bed to wall heat transfer-rates and for the pattern of gas/solids contacting, important in most chemical engineering applications of the technique.

We have recently taken X-ray ciné photographs of these bubbles. Glass spheres 0·5 mm. in diameter were fluidized by air in a 14-cm. diameter vessel. The bed was 24 cm. deep and the field of view was 12 cm. diameter centred about half-way up the bed. A pulsed

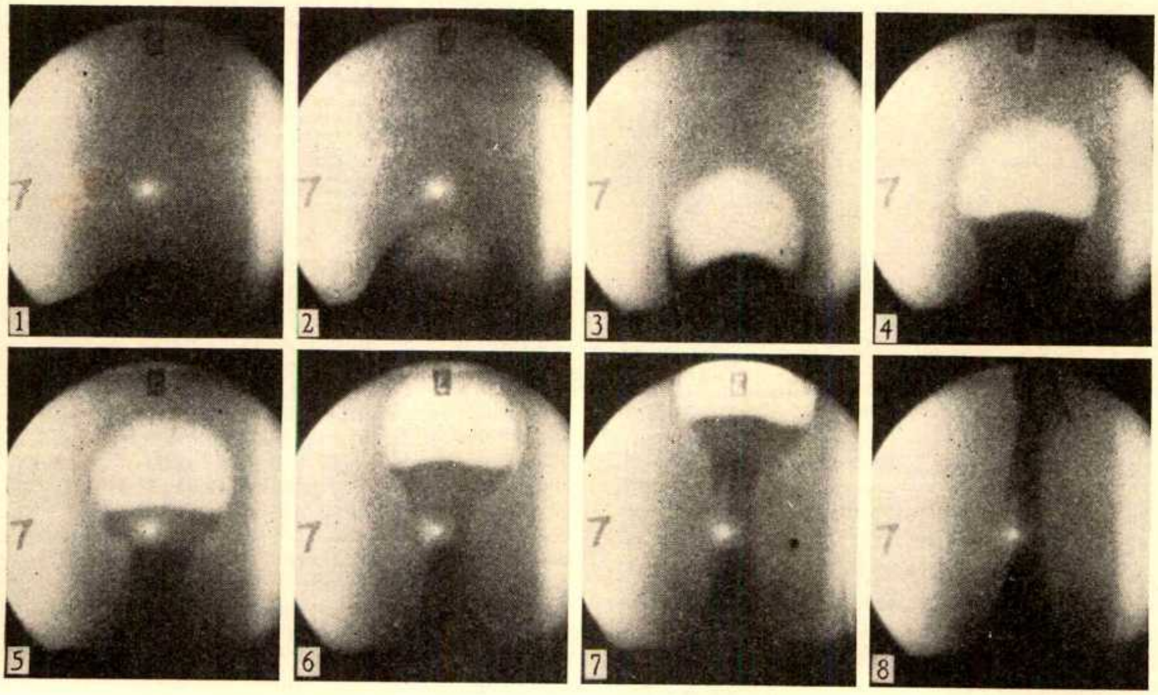

Fig. 1

X-ray source and an image intensifier were used and ciné photographs were taken at 25 frames per second with an exposure time of 1/100 sec.[1]. In one experiment, the lower half of the bed was made up of lead glass spheres and the upper half of soda glass with a horizontal interface between them originally. A bubble was filmed as it crossed this boundary, and the movement of a horizontal layer of particles was followed as well as the bubble itself.

The sequence of movement is shown in the series of photographs (Fig. 1). In the first, a bubble is lifting the darker lead glass spheres up and away from its path. Particles slip round the bubble and in the second picture it is just visible through a curtain of lead glass. The outline of the bubble is plainly visible in the third picture with the last of the lead glass draining from its lower edges. It is seen to be about 5 cm. in diameter. As it continues to rise, a spout of the identifiable lead glass is drawn up behind it and, in the fourth, fifth, sixth and seventh pictures, a wake containing the dark particles is seen to be travelling with the bubble. It finally leaves a vertical drift profile[2] surrounded by barb-like fragments shed from the wake. (The central light spot and light bands at the sides in all the photographs are optical effects and should be ignored.)

The bubble is empty and its shape corresponds closely to that of a sphere with the bottom cap (of height about 2/5 sphere diameter) removed. The wake region behind the bubble is seen to be defined approximately by this cap. The rate of rise of the bubble is in good agreement with Davies and Taylor's[3] value for gas bubbles in an inviscid liquid as proposed by Davidson and others[4]. The bubble is growing in diameter slightly as it rises. The final drift profile of the eighth picture has already been reported by Rowe and Partridge[5] and is a direct consequence of the streamline flow of particles around the bubble.

From other photographs we have seen that bubbles frequently split or coalesce so that measurements of bubble velocity that do not define the instantaneous bubble size and state may be misleading.

CHEMISTRY

Reaction of Hydrogen Peroxide and Nitric Oxide

RECENT work[1,2] on the nitrogen dioxide sensitized hydrogen–oxygen reaction has shown that at 360° C. the reaction:

$$HO_2 + NO \rightarrow OH + NO_2$$

is fast relative to other reactions of HO_2 in that system. On this evidence it was predicted[1] that at similar temperatures hydrogen peroxide and nitric oxide would react by a chain mechanism, since above 420° C. hydrogen peroxide decomposes homogeneously by a mechanism[3] involving the radicals OH and HO_2. This prediction has now been verified and a preliminary investigation of the reaction is described here.

The overall reaction was found to be:

$$H_2O_2 + NO \rightarrow H_2O + NO_2 \qquad (1)$$

and the initial rate of formation of NO_2 is given by equation (I).

$$\mathrm{d}P_{NO_2}/\mathrm{d}t = \frac{k.P_{H_2O_2}^{\,x}}{P_{N_2}} \qquad (I)$$

The value of x is dependent upon the nitrogen pressure and lies between 1·6 and 1·9. The initial rate is independent of both the nitric oxide pressure and the vessel diameter.

The reactions were examined in plane-ended cylindrical quartz vessels by continuous measurement of the nitrogen dioxide concentration and of the total pressure. The former was recorded using a double-beam photometer[1,4], and the latter with a bourdon gauge manometer[5]. 99·2 per cent w/w unstabilized hydrogen peroxide was used. The reactants were pre-mixed before admission to the reaction vessel, and an excess of nitrogen was present in all experiments.

It has been shown that NO_2 is rapidly formed from H_2O_2 and NO at temperatures from 297° to 473° C. Equation (I) summarized the results of a detailed investigation at 299° C. in which the NO pressure was varied from 1 to 25 mm., the H_2O_2 pressure from 1 to 14 mm. and the N_2 pressure from 30 to 300 mm. Neither a change of vessel diameter from 15 to 38 mm. nor a change of mixing time from 5 to 300 sec. affected the rate. The order with respect to H_2O_2 varied from 1·86 ± 0·06 at 300 mm. total pressure to 1·68 ± 0·10 at 100 mm. In many experiments a pressure decrease was observed in the early stages of the reaction. The rate of this decrease rarely exceeded 10 per cent of the simultaneous rate of NO_2 formation.

It was concluded that equation (I) was consistent with the stoichiometry of the reaction since more than 90 per cent of the initial NO present might be accounted for by the NO_2 formed with only a small concurrent change in pressure. However, the decrease in pressure does indicate the presence of a minor product during the initial reaction, accounting for up to 10 per cent of the total products.

The form of the rate equation (I) excludes the possibility of a homogeneous molecular reaction, and a heterogeneous path is unlikely in view of the lack of diameter dependence. The possibility of an initial rate-determining decomposition of H_2O_2 to oxygen, followed by the combination of NO and O_2, may be rejected since the rates of formation of NO_2 are much greater than those expected from the termolecular reaction. Thus it is concluded that a homogeneous radical reaction occurs. Of the possible schemes considered[1], only the following leads to the correct rate equation :

$$\begin{array}{rll}
H_2O_2 + NO \rightarrow & HNO + HO_2 & \\
 & HNO_2 + OH & k_2 \\
 & HNO_3 + H \rightarrow OH \text{ or } HO_2 & \\
OH + H_2O_2 \rightarrow & HO_2 + H_2O & k_3 \\
HO_2 + NO \rightarrow & OH + NO_2 & k_4 \\
OH + NO + M \rightarrow & HNO_2 + M & k_5
\end{array}$$

The application of the stationary state hypothesis to this scheme, assuming long chains, leads to the rate equation (II) :

$$\mathrm{d}P_{\mathrm{NO}_2}/\mathrm{d}t = \frac{k_2k_3.P_{\mathrm{H_2O_2}}{}^2}{\Sigma k_{5,M}.P_M} \qquad \text{(II)}$$

This is in good agreement with the experimental equation (I) apart from the order with respect to H_2O_2. The most probable causes of this discrepancy are either that the long-chain assumption is not valid, or that H_2O_2 is an efficient third body in reaction (5) relative to nitrogen. At present there is no evidence to suggest a choice between the alternative initiation reactions.

The reaction scheme does not account for the pressure decrease observed unless nitrous acid can accumulate at this temperature, which is improbable on thermodynamic grounds[6]. It is more likely that the decrease is due to the establishment of a stationary concentration of nitric acid, since this decomposes slowly at 300° C.[7], and could be formed in the system. Equation (I) does not apply to the variation of the rate within a single run. This effect has not been examined in detail, but it is probably due to secondary reactions caused by the products. In particular, it has been found that H_2O_2 and NO_2 react at both 70° and 299° C., and at the lower temperature this reaction, followed by changes in P_{NO_2} and total pressure, conforms to the equation:

$$2NO_2 + H_2O_2 \rightarrow 2HNO_3$$

It is intended to investigate further both the reaction with NO and with NO_2.

I wish to thank Dr. P. G. Ashmore for many helpful discussions during the course of this work, and Laporte Chemicals, Ltd., for a gift of hydrogen peroxide.

Bromination of Triphenyl Phosphine Borine

In most compounds containing hydrogen linked to boron, the hydrogen atoms have a more or less pronounced electronegative or hydridic character. This is evident in the mildness of the conditions required for their reaction with water or hydrogen chloride to give molecular hydrogen. In the phosphinoborine ring polymers, however, the BH_2 groups are exceptionally inert towards hydrolysis. Burg *et al.* have attributed this to a diminution in the hydridic character of the hydrogen atoms, caused by partial utilization of the B–H bonding electrons in forming π bonds between the boron and phosphorus atoms[1–3]. Triphenyl phosphine borine, $(C_6H_5)_3P.BH_3$, is another unusually inert boron hydride derivative. Since our preliminary report that it resisted hydrolysis[4], we have found that it is not affected by refluxing for 1 hr. with 6 *N* hydrochloric acid; nor, when dissolved in benzene, does it react with hydrogen chloride gas at room temperature. This stable (m.p. 188°) and easily prepared compound appeals to us as a material with which to investigate the chemical behaviour of deactivated hydrogen atoms attached to boron. We here report the first of a series of experiments by means of which we hope to characterize more fully the type of reactivity possessed by these hydrogen atoms.

Triphenyl phosphine borine was first made by passing diborane into a benzene solution of triphenyl phosphine. Using high-vacuum apparatus, bromine was distilled into a suspension of the triphenyl phosphine borine in dry carbon disulphide. Reaction occurred smoothly at −40° according to the equation:

$$(C_6H_5)_3P.BH_3 + 3Br_2 \rightarrow 3HBr + (C_6H_5)_3P.BBr_3$$

The second reaction product was identified by comparison with a specimen of the triphenyl phosphine–boron tribromide complex prepared by mixing the components in carbon disulphide solution. The two substances gave: (*a*) indistinguishable infra-red spectra (potassium bromide disk method); (*b*) agreeing melting points (reaction product 212°–214°, $(C_6H_5)_3P.BBr_3$ 215°–217°, mixed m.p. 214°); (*c*) the same hydrolysis products, when refluxed for an hour with carbon tetrachloride and water.

Table 1

Reactants		HBr formed *, †	From hydrolysis of involatile reaction product‡	
$(C_6H_5)_3P.BH_3$	Br_2		H_3BO_3	BHr †
0·855	2·56	2·54	0·85	2·57
0·873	2·62	2·59	0·87	2·64

All quantities in m.moles. Reaction in 1·5 ml. of carbon disulphide at −40°.

* Pumped off from reaction mixture at room temperature.

† Determined both gravimetrically as silver bromide and acidimetrically.

‡ The hydrolysis also gave rise to triphenyl phosphine oxide, which was not determined quantitatively. This presumably arose from atmospheric oxidation of the triphenyl phosphine first formed; it was also formed in experiments in which triphenyl phosphine or its boron tribromide adduct were refluxed under the same conditions.

Table 1 shows the practically quantitative stoichiometry of the reaction.

Taken in conjunction with the known lack of hydridic reactivity of the borine hydrogens in this compound, the reaction with bromine may well imply protonic ionization of the borine hydrogens, leading to their replacement by bromine in an S_E1 process. But more experiments are needed before alternative mechanisms, such as fission of the P–B bond by bromine and its subsequent re-formation, can be ruled out.

Reaction of Phenols with Peroxy Radicals

Although it has been known for a long time that phenols inhibit the autoxidation of many organic substances, the exact nature of the inhibition process is still not completely understood[1]. Most experimental evidence suggests that the reaction involves a straightforward abstraction of the phenolic hydrogen by the substrate peroxy radicals to give a hydroperoxide and a comparatively unreactive phenoxy radical:

$$ROO\cdot + \varphi OH \rightarrow ROOH + \varphi O\cdot \qquad (1)$$

However, several workers have shown that replacement of the phenolic hydrogen by deuterium has

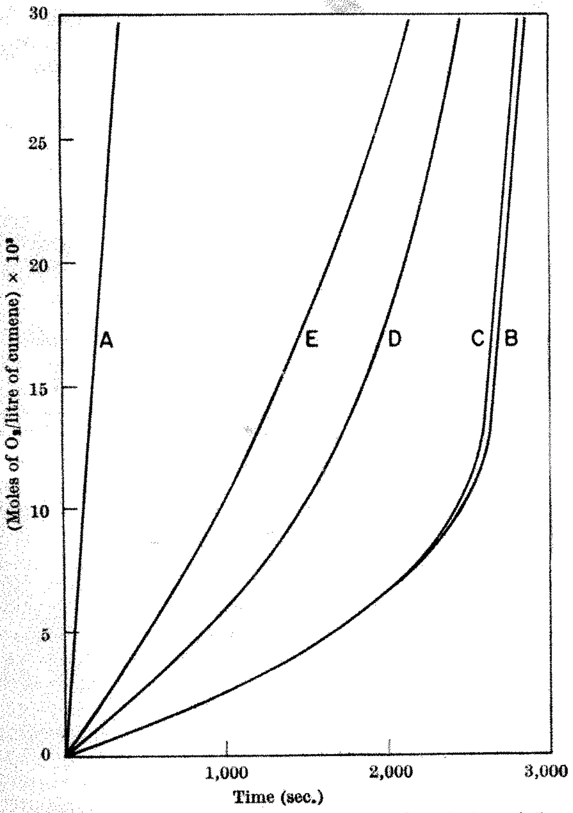

Fig. 1. Oxidation of cumene at 65° C. initiated by 0·327 mole/l. of AIBN and inhibited by 10^{-2} moles/l. of BMP. *A*, Uninhibited oxidation; *B*, BMP inhibited; *C*, BMP inhibited + water; *D*, deuterated BMP inhibited; *E*, deuterated BMP + deuterium oxide

either no effect, or else only a comparatively small effect (~ 0–60 per cent) on the rate of this reaction[1–3]. It has therefore been suggested that the rate-determining step involves the prior formation of a complex between the peroxy radical and the phenol followed by a rapid, non-rate determining, hydrogen abstraction[1,2]. Alternatively, small isotope effects could be secondary effects or could arise in abstraction from the activated complex[3]. We have now found that the apparent smallness or complete absence of the expected isotope effect is most probably due to the very rapid exchange that occurs between a deuterated phenol dissolved in an organic substrate and traces of moisture or the hydroperoxide products of oxidation. The oxidation of cumene under 760 mm. of oxygen initiated by α,α′-azo-*bis*-isobutyronitrile (AIBN) was studied in a conventional constant pressure apparatus. The oxidation was partially inhibited by 2,6-di-*tert*-butyl-4-methylphenol (BMP). In the presence of this inhibitor the initial rate is quite low, but it rises to the rate of the uninhibited reaction as soon as the inhibitor is consumed. This initial rate is proportional to the AIBN concentration and inversely proportional to the BMP concentration, and its reciprocal is proportional to the rate of reaction 1. We have found that exchange can be partially suppressed by using rather high concentration of deuterated BMP and that under these conditions a fairly large isotope effect is observed which increases as the inhibitor concentration is increased. For example, some preliminary experiments at 70° C. with an AIBN concentration of 0·34 mole/l. gave measured isotope effects of 1·6, 1·8 and 2·2 at BMP concentrations of 10^{-2}, 2×10^{-2} and 4×10^{-2} moles/l. respectively. Theoretically, the true isotope effect in the absence of exchange could be obtained by extrapolating to infinite inhibitor concentration. A simpler and, probably, much more accurate procedure is to add an excess of deuterium oxide to the reaction system (~ 1·0 c.c. D_2O to 5 c.c. cumene), thereby maintaining the BMP in its fully deuterated state throughout the early part of the reaction in which the rates are measured. Fig. 1 shows some results obtained in this way at 65° C. with an AIBN concentration of 0·327 mole/l. and a BMP concentration of 10^{-2} moles/l. In the presence of deuterium oxide the initial rate is ⩾ 4·2 times that obtained with the undeuterated inhibitor, whereas, in the absence of deuterium oxide, this factor was only 2·3. That is, from the average of three determinations, the true deuterium isotope effect for reaction 1 between cumyl peroxy radicals and BMP at 65° C. is ⩾ 4·2 ± 0·5. Our assumption that the major, and possibly only, part played by the deuterium oxide is to maintain the BMP in its fully deuterated state is confirmed by the fact that water has no appreciable effect on the undeuterated inhibitor (see Fig. 1) and that the effects of water and deuterium oxide on the uninhibited oxidation are very small. Experiments of a similar nature using styrene as the substrate gave an isotope effect of about 10·6 at 65° C.

In conclusion, the reaction between phenols and peroxy radicals does not show the unusual features previously reported. That is, the reaction of 2,6-di-*tert*-butyl-4-methylphenol with both tertiary and secondary peroxy radicals is a normal hydrogen abstraction process exhibiting an isotope effect of about the expected magnitude for a transition state involving appreciable stretching of the phenolic O–H bond.

BIOCHEMISTRY

Disk Electrophoresis of Basic Proteins and Peptides on Polyacrylamide Gels

DISK electrophoresis on small columns of polyacrylamide gels, a new method for the separation of serum proteins, has been developed by Ornstein and Davis[1,2].

We have modified their procedure to make possible the separation of basic proteins and peptides[3]. This technique permits excellent resolution of mixtures of proteins or peptides with samples as small as 50 μgm. and within as little as 20 min. The method achieves this by concentrating the components of dilute samples into very thin starting zones and by utilizing the frictional properties of the gel to aid separation by molecular sieving.

Disk electrophoresis is carried out in columns of polyacrylamide gel consisting of three sections: (1) a large-pore anticonvection gel containing the protein sample; (2) a large-pore spacer gel in which electrophoretic concentration takes place; and (3) a small-pore gel in which electrophoretic separation is accomplished. Buffer trays, graphite electrodes and

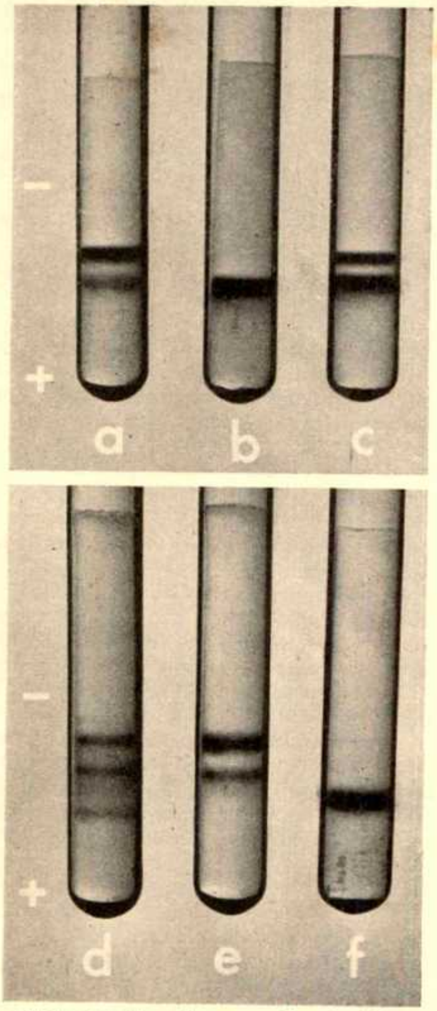

Fig. 1. Electrophoretic patterns. *a*, Trypsin (Worthington, crystallized three times); *b*, chymotrypsin (Worthington, crystallized three times); *c*, 1 : 1 mixture of trypsin and chymotrypsin. Porcine α-melanocyte-stimulating hormone during various stages of purification (*d*, *e*, *f*)

a power supply (300 V., 200 m.amp.) complete the arrangement.

Glass tubes (7 × 0·5 cm. internal diameter) are tightly closed at one end with flat-topped rubber stoppers. Standing upright on these stoppers, the tubes are each filled with 0·85 ml. of small-pore solution (see below for preparation) at room temperature. This solution is carefully overlaid with 0·1 ml. of distilled water and allowed to polymerize for 30 min. The water layer is removed, and the remainder of each tube rinsed once with large-pore solution, after which 0·15 ml. of this solution is added and carefully overlaid with 0·1 ml. of distilled water. A daylight fluorescent lamp (15 W.) is placed behind the tubes, about 3 in. away. The large-pore solution becomes opalescent and polymerizes within 15 min. The water layer is removed and large-pore solution (0·15 ml.), which is mixed with a sample of 50–200 μgm. of protein contained in 5–10 μl., is added. Whenever this amount of sample is contained in a larger volume, the large-pore gel must be applied in a concentration sufficiently higher to offset this dilution. The sample layer is photopolymerized for 15 min. The remaining space in each glass tube is filled with tray buffer (β-alanine acetate), the rubber caps are removed, and the tubes, sample gel uppermost, are attached to the anode buffer compartment, which is then filled with tray buffer. A hanging drop of buffer is attached to the bottom of each tube. The anode compartment, supported on a ring stand, is placed so that the tubes are immersed about ¼ in. into the buffer contained in the cathode compartment. An alternative method of sample application is to layer the sample solution (up to 0·15 ml.) on the spacer gel after the anode compartment is filled with buffer. To prevent mixing, the density of the sample solution is increased with sucrose. Electrophoresis is carried out by applying a current of 6–8 m.amp. per tube for 20 min.

When a current is applied, the β-alanine–potassium ion boundary, originally present at the buffer-gel interface, moves into the gel towards the cathode, sweeping up the protein components. The proteins are concentrated between the potassium and the β-alanine in a series of disks in order of electrophoretic mobility. The ratio of the concentrations of the proteins in these disks to that of the potassium ions is equal to the ratio of the respective mobilities per single charge[4]. When the stack of disks passes into the small-pore gel, the β-alanine–potassium ion boundary is accelerated in this region of lower *p*H and the protein disks are left behind. The disks are now in a linear voltage gradient, each in a very thin starting zone. The protein components separate according to charge and molecular size.

When electrophoresis is completed, the gels are immediately removed from the glass tubes by gently rimming them with a 22-gauge syringe needle through which a thin stream of water is allowed to pass. The gels are fixed and stained for 1 hr. in a solution of 1 per cent 'Amidoschwarz' in 7 per cent acetic acid. Background stain is removed electrophoretically by placing the gels into glass tubes (7 × 0·8 cm. internal diameter). One end of each tube is slightly tapered to hold a ¼-in. plug of small-pore gel (7·5 per cent acrylamide). The de-staining tubes and buffer reservoirs are filled with 7 per cent acetic acid. A current of 15 m.amp. per tube is applied, allowing the excess dye to flow towards the anode. All background stain can thus be removed in 30–40 min. The gels are stored in screw-cap vials containing 7 per cent acetic acid.

The following stock solutions are necessary to prepare the small-pore and large-pore solutions:

(*A*)	*N* Potassium hydroxide	48 ml.
	Acetic acid (glacial)	17·2 ml.
	Tetramethylethylenediamine	4·0 ml.
	Water to make	100 ml.
(*B*)	*N* Potassium hydroxide	48 ml.
	Acetic acid (glacial)	2·87 ml.
	Tetramethylethylenediamine	0·46 ml.
	Water to make	100 ml.
(*C*)	Acrylamide	60 gm.
	Methylene *bis*acrylamide	0·4 gm.
	Water to make	100 ml.
(*D*)	Acrylamide	10 gm.
	Methylene *bis*acrylamide	2·5 gm.
	Water to make	100 ml.
(*E*)	Riboflavin	4·0 mgm.
	Water to make	100 ml.

The tray buffer (*p*H 4·5) is prepared as follows: β-alanine, 31·2 gm.; acetic acid (glacial), 8·0 ml.; water to make 1 litre.

The following working solutions are prepared from the stock solutions:

Small-pore solution (*p*H 4·3)
1 part *A*
2 parts *C*
1 part water

This solution is mixed before use with an equal volume of a freshly prepared solution of ammonium persulphate (0 28 gm /100 ml) This will result in a solution containing 15 per cent acrylamide For samples with molecular weights greater than 30,000, a 7 5 per cent acrylamide concentration may be more advantageous To achieve this, stock solution (*C*) is prepared by using 30 gm acrylamide and 0 8 gm of methylene *bis*acrylamide

Large-pore solution (*p*H 6 8)
1 part *B*
2 parts *D*
1 part *E*
4 parts water

All stock solutions have a shelf life of several weeks when stored in brown glass bottles in the refrigerator

The buffer reservoirs can be easily made from polystyrene refrigerator dishes (4–5 in diameter), the anode compartment being prepared by drilling equally spaced holes ($\frac{3}{8}$ in diameter) near the periphery Rubber grommets ($\frac{1}{4}$ in inside diameter) are placed into these holes Each reservoir has a carbon electrode ($\frac{1}{4}$ × $2\frac{1}{2}$ in) fastened at the centre

Fig 1 depicts some of the results we obtained with this method The crystalline preparation of trypsin was shown to be heterogeneous, the minor component having the mobility of chymotrypsin as demonstrated by the electrophoretic pattern of a mixture of equal parts of trypsin and chymotrypsin The chymotrypsin preparation was also shown to contain a minor component A preparation of porcine α-melanocyte-stimulating hormone is shown during various stages of chromatographic purification The final product appears to be homogeneous We have also found inhomogeneity in the following preparations ribonuclease (Worthington, crystallized three times), one major and three minor components, protamine sulphate (Nutritional Biochemicals Corporation), one major and three minor components, globin (Nutritional Biochemicals Corporation), one major and four minor components, lysine vasopressin (N I H , Endocrinology Study Section), two major and four minor components

The method makes it possible to analyse eluate fractions from column chromatography since one person can analyse as many as 20–30 samples per day We have found the method to be highly reproducible, as well as rapid, simple, and most inexpensive to set up

Polyribonucleotide-directed Protein Synthesis using an *E. coli* Cell-free System

Since the discovery by Nirenberg and Matthaei[1] that a synthetic polynucleotide, when added to an *E coli* cell-free system, led to the synthesis of a specific polypeptide, various groups have used similar methods to find code letters for the common amino-acids We should like to report certain observations, some of which are at variance with those already published

Nirenberg and Matthaei's original observation, that poly U coded specifically for phenylalanine, appeared to give a clear path for the solution of the genetic code, assuming a triplet nature for the code[2], one sequence for phenylalanine would be UUU Using, in general, polymers composed of uridylic acid residues, with small amounts of the other bases, C, A, G or I, Ochoa *et al* have produced code letters for nineteen amino-acids and have predicted the twentieth[3–5] Many of these triplets have been confirmed by Matthaei *et al*[6] Several code letter assignments depend on the incorporation of an amino-acid in small amounts, stimulated by a polymer the composition of which has frequently been left unanalysed, but is assumed to have the same overall composition as the reaction mixture from which it was made[3–5] That analysis is essential is shown by the composition of reaction mixture and product of several polymers we prepared (Table 1), though naturally results may differ somewhat for enzymes from different sources and with different incubation conditions

Table 1

	μM reactants	Analysis of product
Poly UC	40 UDP + 37 5 CDP	C/U = 1 9
Poly AC	40 ADP + 40 CDP	C/A = 1 7
Poly UG	25 UDP + 25 GDP	G/U = 32
Poly UCG	59 5 UDP + 10 5 CDP + 10 5 GDP	U/C/G = 2 1 1

Comparison of reactant concentrations and product composition using a polynucleotide phosphorylase (of specific activity 23) from *Azotobacter vinelandii* Incubation mixture contains per ml 100 *μM tris p*H 8 2, 10 *μM* magnesium chloride and 2 units of enzyme for poly UC and poly AC, or 10 units of enzyme for poly UG and poly UCG.

In assigning a triplet, the ratio of incorporation of the amino-acid to that of a standard (generally phenylalanine) is compared with the composition of the polymer This assumes that the polymer is random in sequence, that peptides of different compositions are detected with equal efficiency (usually insolubility in hot trichloroacetic acid), and that only one triplet is read for the standard (for example, UUU) The latter two assumptions appear to be unlikely

It seems possible, therefore, that in some cases the stimulations observed may be caused by triplets other than those to which the code letters have been assigned

Evidence for the degeneracy of the code has been provided by the stimulation of leucine by poly UC and poly UG[5,7], and by poly UA[5] Serine is reported to be represented by UUC and UGC[6], asparagine by UAA and UAC[5], and threonine by UAC[5] and originally by UCC[4]

We find that in a similar cell-free system the stimulation of amino-acid incorporation by poly U is not limited to phenylalanine, but that variable amounts of leucine (5–25 per cent in different experiments) are always incorporated An incorporation of about 3 per cent leucine has also been reported by Matthaei[6] Both the time course and the temperature dependence (tested at 25° C and 37° C) of incorporation are similar for these amino-acids The leucine incorporation is not due to an impurity in our carbon-14 L-leucine sample because a hundred-fold excess of carbon-12 L-leucine (of purity better than one part in a thousand) quenches the incorporation almost completely Five preparations of poly U, with S_{20} values lying between 4 3 and 1 7 (the last prepared by degrading a larger polymer with snake venom phosphodiesterase), have been tested, and no difference in the ability to incorporate leucine could be observed Hydrolysis of a poly U sample showed that the total impurities of C, A, G or I were less than 1 per cent moreover, no poly U sample incorporated serine or proline (expected of a poly UC), isoleucine (expected of a poly UA), or valine (expected of a UG or UI polymer) Two of the poly U samples had been prepared from independent sources of synthetic UDP We conclude that poly U, when placed in this cell-free system, leads to the incorporation of more than one amino-acid This effect indicates either that intact cells make this 'mistake' or that the *in vitro* system has been damaged somewhat, or that a systematic alteration of the polymer has taken place in the reaction mixture Whatever the reason, it suggests that small amounts of incorporation may be misleading, as may be the incorporation of leucine into those polymers which mainly consist of U's

All code letters produced so far have U's in them This seems unlikely since it would give an overwhelming abundance of U's in a hypothetical messenger[8], which would lead one to expect a high A/G base composition for DNA That it is unnecessary for triplets to contain U's is shown by a poly CA (S_{20} = 2 0, made from 4 CDP + 1 ADP, C/A = 5 6, with maximum impurities of 1 per cent U, 0 8 per cent G) This has been tested for 18 amino-acids (the usual 20 except tryptophan and cysteine) and incorporates mainly proline, and smaller amounts of threonine and histidine Another poly CA (S_{20} = 2 9, 1 CDP + 1 ADP, C/A = 1 7) incorporates mainly proline, some threonine and histidine together with a much smaller amount of glutamine Each incorporation has been checked by quenching with the corresponding C12 amino-acid Both these poly CA's function with about equal efficiency (as judged by total incorporation when our system is saturated with polymer), which is about one-third as efficient as a poly CU (C/U = 4 3)

Table 2

	Poly CA C/A = 5 6	Poly CA C/A = 1 7	No polymer
Proline	530	520	17
Threonine	215	350	32
Histidine	70	160	5
Glutamine	58	70	36

Incorporation with these two polymers in $\mu\mu$moles/mgm ribosomes is shown with figures for the incorporation in the absence of polymer Incubation mixture contains per ml 16 μM Mg $(CH_3COO)_2$, 60 μM *tris* *p*H 7 8, 85 μM KCl, 12 μM mercaptoethanol, 1 2 μM ATP, 0 25 μM GTP, 4 5 μM phosphoenolpyruvate, 80 μgm phosphoenolpyruvate kinase (from Boehringer), 1 2 mgm ribosomes, 3 2 mgm concentrated dialysed supernatant, 40 mμM of a carbon-14 L-amino acid and 0 3 μM of each of the other 19 common amino-acids, and 40 μgm of the polymer Samples were incubated at 37° C for 15 min Incorporation was measured by radioactive hot TCA precipitable material

It was originally reported[4] (though more recent work by the same authors has shown this to be unlikely) that a triplet for threonine was UCC With UC polymers of composition U/C = 2 8, 0 7 and 0 23, only slight threonine stimulation could be detected, being always less than 5 per cent of the total incorporation by the polymers This indicates that the UCC assignment is incorrect Matthaei *et al* have come to a similar conclusion It is of interest that these three poly UC's function with roughly equal efficiencies

We conclude that not all codons must contain U, and that the assignment of triplets on the basis of small amounts of incorporation can lead to mistakes

We thank Dr F H C Crick for many helpful suggestions, Dr J Ofengand for details of the protein synthesis system which he developed, and Dr A M Michelson for a sample of chemically synthesized UDP We acknowledge with thanks the award of a Salters' Scholarship (to M S Bretscher), and a grant from the U S National Institutes of Health, No C 45 80 (to Marianne Grunberg-Manago).

Use of Indium Trichloride for the Separation of Native, Denatured and Single-stranded Deoxyribonucleic Acid

A PREVIOUS communication from me[1] described the use of indium trichloride for the separation of DNA and RNA This work has now been extended to the point where it has become possible to separate different molecular species of DNA in the presence of indium chloride and varying concentrations of sodium chloride

Calf thymus DNA isolated by the method of Kay *et al* [2] was dissolved in 0 14 *M* sodium chloride so that a 0 4 per cent solution resulted Aliquots of this solution were taken and subjected to one of the four following experimental conditions (1) no treatment, that is, native DNA, (2) heat denaturation at 100° C for 30 min (this procedure presumably produces single-stranded DNA[3]), (3) denaturation by the addition of glacial acetic acid to a final concentration of 0 2 *M*, (4) denaturation by addition of 19 *M* potassium hydroxide to a final concentration of 1 *M* (the solution was allowed to stand for 1 hr)

To the acid and alkali denatured aliquots, 2 vol of absolute ethanol were added and the solution was equilibrated at 0° C for 2 hr The resulting precipitates collected by centrifugation were washed with 70 per cent ethanol and re-sedimented The denatured DNA was then redissolved in 0 14 *M* sodium chloride to give a 0 4 per cent solution and the *p*H adjusted to 7 0 with a small amount of either 0 2 *M* acetic acid or 0 2 *M* potassium hydroxide

In a system the total volume of which was 5 0 ml , indium precipitation of the 4 different species of DNA at *p*H 5 (Fig 1) was examined as a function of concentration of sodium chloride The system contained the following 0 5 ml DNA solutions, 3 5 ml 0 2 *M* acetate buffer, *p*H 5 0, containing sodium chloride in the range 0 14–5 7 *M*; and 1 0 ml of 0 05 *M* indium chloride in distilled water (freshly made) rapidly blown in and mixed After standing at room temperature for 30 min , the tubes were centrifuged at 1,400*g* for 10 min and the absorbance of the supernatant solutions at 260 mμ determined The presence of 260 mμ-absorbing material indicates that the nucleic acid has not been precipitated Results

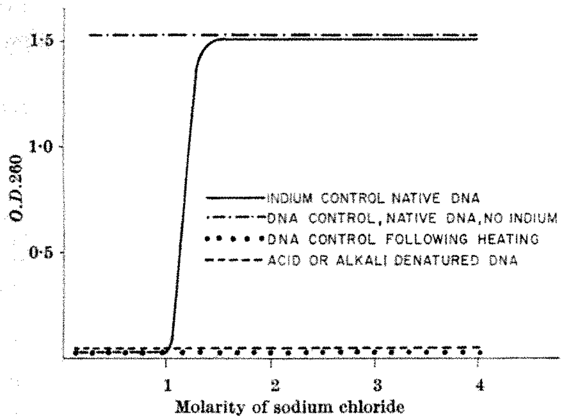

Fig. 1. DNA remaining in the supernatant solution after addition of indium chloride to solution of DNA treated in the manner indicated in the text. Only 'native' double-stranded DNA becomes unprecipitable in 1·5 and higher molarities of sodium chloride at pH 5. Measurements were made on the basis of increments of 0·1 M sodium chloride in the range 0·1–4 M

obtained in this manner on the four DNA aliquots are plotted in Fig. 1.

From these results it is apparent that native, double-stranded DNA was not precipitated by indium chloride at pH 5 in the presence of 1·5 M or higher molarities of sodium chloride. Acid, alkali and heat denatured (presumably single-stranded) DNA was precipitated regardless of the concentration of sodium chloride.

Furthermore, it has been found that precipitation of pneumococcal transforming DNA by indium chloride and subsequent removal of indium with versene does not alter the pneumococcal transforming activity. Pneumococcal DNA had properties similar to those shown in Fig. 1 for calf thymus DNA. The indium precipitates of DNA have also been found to be insensitive to digestion by DNase.

Indium complexes of yeast and rat liver RNA (like those of RNA of tobacco mosaic virus[4]) were also found to be insensitive to digestion by RNase.

It is possible to examine different molecular species in a nucleic acid preparation using the basic information presented here. As an example, nucleic acids isolated from rat liver and separated according to the indium technique[1] always yield an RNA fraction contaminated with a small amount of DNA. This DNA can be examined by placing the precipitate (DNA and RNA) in a solution of DNase I (1 mgm./ml.) and RNase (1 mgm./ml.) in 0·14 M sodium chloride plus 0·002 M magnesium sulphate buffered at pH 5 with acetate. These enzymes will digest completely only the nucleic acid not present as the indium complex. In order to digest indium complexed RNA, sodium duodecyl sulphate is then added to a concentration of 1 per cent. This completely inhibits DNase I activity but only about 60 per cent of the RNase activity. By adding versene, the indium is removed from the nucleic acids and only RNA is digested on incubation for 2 hr. at 37° C. The mixture is heated to 50° C. for 30 min. to denature completely both enzymes, and solid sodium chloride is added to a concentration of 1·5 M to precipitate the detergent and detergent-protein complex. Following centrifugation, the solution is dialysed against several portions of 0·14 M sodium chloride at 4° C. to remove low molecular-weight degradation products of RNA. The resulting dialysed solution of DNA may now be further studied.

Some of this work was done while I was the recipient of a National Institutes of Health post-sophomore research fellowship. It was supported, in part, by a contract with the U.S. Atomic Energy Commission (AT(30–1)–1286) and, in part, by the Ernest L. Woodward Fund of the University of Rochester School of Medicine and Dentistry.

Multiple Nature of Acetylcholinesterase in Nerve Tissue

WITHIN recent years much evidence has been presented on the multiple nature of enzymes. Such enzyme systems as dehydrogenases[1], esterases[2], phosphatases[3], etc., have been shown by various kinetic, electrophoretic and column separation techniques to exist as more than one molecular specie. It is too early to assess the significance of variations in properties of these similar substances because of the paucity of information correlating their biochemical nature and physiological functions. However, a large body of knowledge has accumulated on the physiological function of acetylcholinesterase relating it to the propagation of the nerve impulse. Data on the unitary or multiple nature of acetylcholinesterase in nervous tissue might lead to specific information on the relation of the enzyme to the nerve conduction process, or might shed light on the general problem of the physiological meaning of the occurrence of multiple molecular enzyme species. Bergmann and Segal[4] have already shown that more than one acetylcholinesterase may be present in dog tissue and the multiple nature of serum cholinesterases in a variety of animals has been reported[5,6].

In order to obtain an adequate source of the enzyme from nervous tissue, the caudate nucleus and putamen of human brain were dissected from post-mortem material. These nuclei have been shown to possess high enzymatic activity[7], and were obtained 4–8 hr. after death. The homogenate was assayed by the conventional manometric technique and was found to hydrolyse 1,375 μmoles acetylcholine/gm. brain/hr. The dissected tissue was homogenized with an equal volume of isotonic saline and the homogenate was then frozen and thawed six times, and centrifuged at 20,000g. The supernatant was pipetted, placed in a 'Visking' bag, and the volume reduced to 1/3–1/4 of the original by passing a current of air across the bag in a refrigerator at 4° C. (ref. 8). The concentrated extract was then subjected to starch-gel electrophoresis according to Smithies[9] for 16–18 hr. at an e.m.f. of 4·5 V./cm. in a 13° C. incubator. After the separation was completed, the starch block was cut longitudinally and incubated in the appropriate medium using acetylthiocholine or butyrylthiocholine iodides as substrates by a method previously described[6] and derived from that of Gomori[10].

The acetylcholinesterase activity obtained at *p*H 6·2 and *p*H 5·0 with acetylthiocholine as substrate is shown in Fig. 1. At *p*H 6·2, four zones of activity could be demonstrated. A dense zone, well delineated at its forward boundary but with some tailing at the trailing edge, was obtained proximate to the origin (*A*). In addition a zone practically as dense as (*A*) was present distal from the origin (*D*). Almost contiguous with (*D*), but of lighter intensity, another band of acetylcholinesterase activity was present (*C*), and a light band of activity intermediate between the dense zones could be shown (*B*).

When the starch block was incubated at a *p*H of 5·0, zones *A*, *C*, and *D* disappeared, but band *B* became intensified. The absence of activity of the enzyme at *p*H 5·0 is in agreement with the results of Wilson and Bergmann[11]. In addition, inhibitor experiments showed that bands *A*, *C* and *D* are completely inhibited by incorporation of physostigmine sulphate in the gel and afterwards in the substrate medium at a concentration of 1×10^{-5} *M*. Further evidence that the zones of activity at *A*, *C* and *D* are due to acetylcholinesterase is provided by the fact that the use of butyrylthiocholine (Fig. 1, II) results in a great diminution in intensity of bands *A*, *C*, and *D*, while band *B* has a density which is similar to that obtained with acetylthiocholine. Inhibition experiments with the specific acetylcholinesterase inhibitor mytelase (5×10^{-6} *M*) resulted in complete inhibition of zones *A*, *C*, and *D*.

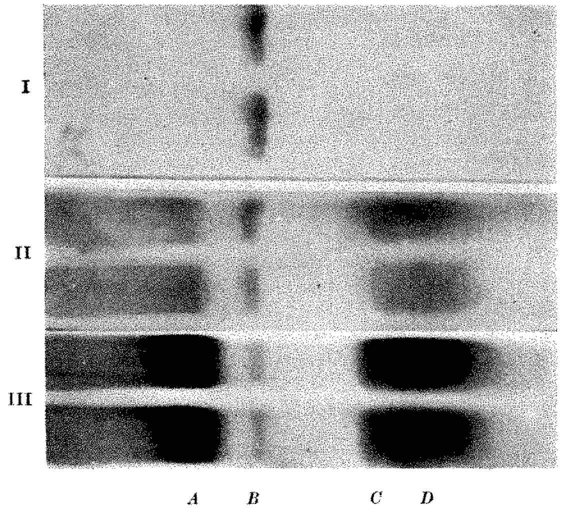

Fig. 1. Separation of acetylcholinesterase from brain (caudate nucleus and putamen) by starch-gel electrophoresis. The block letters refer to the bands of activity. (I) Acetylthiocholine as substrate at *p*H 5·0. (II) Butyrylthiocholine as substrate, *p*H 6·2. (III) Acetylthiocholine as substrate, *p*H 6·2

In view of the results obtained, namely, inhibition by physostigmine sulphate and mytelase, absence of activity at *p*H 5·0 and a greater activity for the 2-carbon acyl chain as compared to the 4-carbon chain, it would appear that zones *A*, *C* and *D* have enzymatic properties usually associated with acetylcholinesterase. Whether these 'isozymes' represent different molecular species is a problem of paramount interest in view of the physiological function ascribed to this enzyme. If they represent different molecular species, then it would seem that either the enzyme has more than one biochemical function in the mechanism of nerve conduction, or the variations in molecular structure reflected in the varying mobilities found in this work have no effect on the enzyme-substrate relationship in terms of the various parameters that have been studied by others. It is possible that the differences found here represent some multiple aggregate of a basic structure required for enzymatic activity. Our present knowledge of the active centre of the enzyme relates to the presence of an anionic and an esteratic site, spatially oriented so as to form an enzyme-substrate complex with acetylcholine. Information as to whether the intact enzyme is necessary for catalytic activity or whether some essential fragment can substitute for the whole protein molecule is lacking. It may be true that the different zones of activity obtained in this work represent enzymes with different functions, in which case the present concepts of acetylcholine metabolism may need some revision. This laboratory is at present engaged in characterizing the bands that have been resolved.

This work was aided by a grant from the National Multiple Sclerosis Society.

Non-Casein Proteins of Goat's Milk

EXISTENCE of genetically different types of β-lactoglobulin[1,2], α-lactalbumin[3] and β-casein[4] have been demonstrated in cow's milk; but no genetic polymorphism was detected in the non-casein proteins of buffalo's milk[5]. We have investigated the probable occurrence of genetically controlled proteins in the non-casein fraction of goat's milk from which the β-lactoglobulin and 'lactalbumin' have been crystallized and some of their physicochemical properties examined.

Twenty-three breeds of Indian goats are known to exist[6]. Of these Jamnapari, Black Bengal, Barbari and a few crosses between Saanen and Indian breeds were available for investigation. More than 75 samples of milk of individual goats were examined. Protein solutions for tests were prepared by the method of Aschaffenburg and Drewry[2] and subjected to paper electrophoresis in a hanging strip apparatus at *p*H 4·9 in acetate buffer, I = 0·05, using Whatman 3 *MM* paper and applying a voltage of 240 V. for 16 hr.

Fig. 1 shows a typical electropherogram. The number of protein components seem to be five, of which β-lactoglobulin, 'lactalbumin' and components III and III*a* migrate towards the cathode and com-

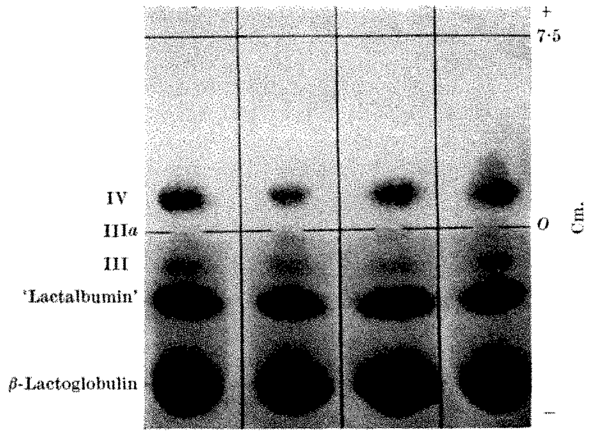

Fig. 1. Electropherogram of non-casein proteins of goat's milk from four individual animals (*O*, origin; bromphenol blue staining)

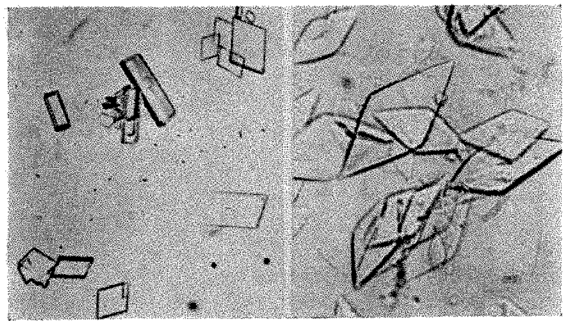
ponent IV to the anode. All the individual samples appear to give uniform results indicating the absence of any genetic factor in the occurrence of non-casein protein constituents of goat's milk in the breeds so far examined.

Two major protein constituents, β-lactoglobulin and 'lactalbumin', have been purified and crystallized. In Fig. 2*a* different forms of crystalline β-lactoglobulin are shown and in Fig. 2*b* crystals of 'lactalbumin', which appear to be rhombohedral. The diamond-shaped crystals of goat β-lactoglobulin seem to be similar to the monoclinic crystals of cow[1] and buffalo[5] β-lactoglobulin.



(*a*) (*b*)

Fig. 2. *a*, Crystals of goat β-lactoglobulin (× *c*. 150); *b*, crystals of goat 'lactalbumin' (× *c*. 360)

The separation and crystallization of β-lactoglobulin and 'lactalbumin' were carried out by the method of Aschaffenburg and Drewry[7] suitably modified by us for goat's milk. According to this procedure, a filtrate containing the non-casein proteins, obtained by addition of sodium sulphate (20 gm./100 ml.) to the whole milk, is adjusted to *p*H 3 when all the protein constituents with the exception of β-lactoglobulin are precipitated. From the filtrate, β-lactoglobulin is precipitated by the usual method[7]. The final concentrated solution of β-lactoglobulin is adjusted to *p*H 5·9 and dialysed against distilled water. A heavy oily layer separates from which the crystals of β-lactoglobulin (Fig. 2*a*) appear in 10–12 days. The β-lactoglobulin precipitate obtained by this method can also be crystallized in the form of hexagonal bipyramids[8].

The acid precipitated proteins are dissolved in water by adding dilute ammonia and freed from any residual β-lactoglobulin by reprecipitating at *p*H 3 in the presence of sodium sulphate (15 gm./100 ml.). This precipitate is dissolved in dilute ammonia, and the *p*H adjusted to 4 with hydrochloric acid. The solution is centrifuged, and from the supernatant 'lactalbumin' is precipitated with ammonium sulphate between 45 and 80 per cent saturation. The precipitate is dissolved in water and the solution after being adjusted to *p*H 6 is rendered slightly turbid by adding ammonium sulphate. This solution when allowed to evaporate slowly gives crystals of 'lactalbumin' (Fig. 2*b*). A salt-free concentrated solution of lactalbumin yields needle-shaped crystals when left in the cold (2°–4° C.).

In preliminary free electrophoresis experiments 'lactalbumin' shows single symmetrical peaks at *p*H 5·2, and its isoelectric point appears to be close to this *p*H. Its sedimentation coefficient, S_{20w}, measured at the same *p*H in a Spinco analytical ultracentrifuge, is $2\cdot 0 \times 10^{-13}$ sec., which is close to the S_{20w} valeus for cow[9,10] and buffalo[11] α-lactalbumins. With β-lactoglobulin, the hypersharp ascending and skew descending electrophoretic patterns obtained at *p*H 5·5 and the S_{20w} value of $2\cdot 9 \times 10^{-13}$ sec. at *p*H 5·7 are similar to those reported by Askonas[8].

We thank the staff of the Haringhata Farm for supplying the milk samples and identification of breeds.

Screening Bacterial Colonies for Penicillinase Production

RECENT syntheses of novel penicillins[1,2] have led to revived interest in the detection of species and strains of bacteria able to destroy penicillin; it has also become important to identify the destructive agent. Screening methods based on substantial diminution of the antibiotic activity of penicillin against Gram-positive bacteria[3,4] or on changes in *p*H associated with the formation of extra carboxyl groups[4,5] have always had a range of application limited by their susceptibility to interference from general metabolic products. It has now become evident that such methods are also unsuitable for distinguishing penicillinase from penicillin acylase[6-8]. But penicillinase converts penicillin to penicilloic acid which, being a thiazolidine with a non-acylated imino group, reacts with iodine; whereas the 6-amino-penicillanic acid formed by penicillin acylase has an intact β-lactam ring and is as inert towards iodine as penicillin itself.

A series of iodometric methods for the specific detection and assay of penicillinase have been described by Perret[9]. We have since developed two simple and flexible modifications which permit the rapid screening of large numbers of bacterial colonies for the aerobic and anaerobic production of both constitutive and induced penicillinase. The exact details of the tests depend to some extent on the nature of the bacteria being tested and on the level of enzyme activity being sought. The particular versions given here were originally devised for the routine screening of strains of *Staphylococcus aureus* in mixed cultures plated-out from clinical material, but they have since proved suitable for both taxonomic and genetic studies of many other species of heterotrophic bacteria.

The test on solid medium is performed by touching selected colonies with a straight wire and transferring each of them to marked positions about 1·5 cm. apart on one or more plates of defibrinated-horse-blood-agar about 0·5 cm. deep. The plates are then incubated at 37° C. for 4 hr., after which time small colonies have formed at the sites of inoculation; if desired, the plates may at this stage be replicated by the velvet-pad technique. Strips of Whatman No. 1 filter paper previously impregnated with fresh 1 per cent starch solution and dried are now immersed in a solution of penicillin *G* (10,000 I.U./ml. in 0·05 *M* phosphate buffer at *p*H 6·5), drained, and laid carefully over the colonies so that air-bubbles are excluded. After 30 min. at room temperature 1 ml. of 0·04 *M* iodine is pipetted on to the paper and the results read up to 30 min. later. Colonies of penicillinase-producers form white spots which increase in area with time; the paper remains blue over non-producers. The limit of sensitivity of the method has not yet been determined, but a strain of *Bacillus cereus* producing only 70 molecules of penicillinase/cell/generation gives clear positive results. When it is important to exclude the possibility of specific enzyme induction the organisms are killed by exposure to chloroform vapour or ethylene oxide before applying the penicillin-impregnated paper.

For some purposes a simpler and quicker procedure may be used. Single colonies are removed from the surface of the primary isolation medium with a loop, emulsified in 0·2 ml. of the penicillin solution in 3 in. × 0·25 in. test tubes and left for 1 hr. at room temperature. One drop (about 0·02 ml.) of equal parts of 1 per cent sodium starch glycollate and 0·04 *M* iodine is then mixed with the contents of each tube. Decolorization ensues rapidly with most penicillinase-producing strains, but the test is recorded as positive if all colour disappears within 5 min.

Both tests should theoretically be accompanied by controls from which penicillin has been omitted; however, we have now tested about 200 strains and species of bacteria from 21 different genera and no false positive results have been detected. The controls therefore seem unnecessary during preliminary screening.

The tests were developed primarily in order to extend the search for naturally occurring penicillin-resistant strains of *Staph. aureus* which do not produce penicillinase[10]. They were therefore initially applied to 151 strains of coagulase-positive staphylococci isolated from clinical sources; 124 strains were penicillinase-positive by both methods, which gave identical results. The strains were then tested for penicillin-sensitivity by means of impregnated disks laid on the surface of spread plates, and by the inoculation of serial two-fold dilutions of penicillin in meat-infusion broth with about 10^7 organisms/ml. All 124 penicillinase-positive strains were resistant to disks bearing 1·5 I.U. penicillin and gave visible turbidity after 18 hr. at 37° C. in concentrations of 0·5 I.U. penicillin/ml. or more: all 27 penicillinase-negative strains were sensitive to the disks and gave no visible turbidity in concentrations of penicillin above 0·25 I.U./ml.

Elastase Activity in Human Pancreatic Secretions

IN 1949, Balo and Banga[1] first reported the isolation of the pancreatic enzyme elastase, which was unique in its ability to render soluble elastin (an important structural component of arteries, veins, skin and lung). This enzyme was first believed to be mucolytic in action, but it is now established that it is also a potent proteolytic agent[2]. Kokas, Foldes and Banga[3], in a series of acute experiments, cannulated the main pancreatic duct of dogs and reported demonstrable elastolytic activity in canine pancreatic secretions. Grant and Robbins[4] in a similar experiment reported that elastase in the pancreas is inactive. They hypothesize that the inactive 'proelastase' must be activated (by small amounts of crystalline trypsin or enterokinase) before elastolytic activity can be demonstrated.

Recently, we have had the opportunity to study a 46-year-old Negro male with a persistent external pancreatic fistula. Approximately 1,000–1,500 ml. of pure pancreatic secretion was discharged daily through the fistula as a colourless, slightly turbid fluid, which ranged in *p*H from 8·15 to 8·52. The amylase concentration of this secretion was consistently high, ranging from 2,000 to 24,000 Somogyi units per 100 ml.

In studies on this patient, secretions were collected at 30-min. intervals. After two fasting collections, the patient was fed a standard meal and collections were carried out for 5 hr. Utilizing a colorimetric method developed in this laboratory[5], 1-ml. aliquots of the pancreatic secretion were assayed for elastase activity. Ordinarily, the freshly collected pancreatic secretion had negligible elastolytic properties. However, when 0·2 mgm. of crystalline trypsin was added to each aliquot, considerable elastolytic activity was demonstrated. Using a previously prepared nomogram[5], correlating optical density with concentration of crystalline porcine elastase, the activity of elastase in each sample was determined.

Table 1 contains the results from a representative 6-hr. secretion study with this patient. There was a prompt increase in elastolytic activity in the 30-min.

Table 1. ELASTOLYTIC ACTIVITY IN HUMAN PANCREATIC SECRETION

Time (min)	Activated elastase activity (μgm /ml)	Non-activated elastase activity (μgm /ml)	Volume of secretion (ml /30 min)	Total elastolytic action (μgm /30 min)
Fasting				
30	12 5	0 0	22 0	275 0
60	14 0	0 0	15 0	210 0
Post-prandial				
30	18 0	<1 0	53 0	954 0
60	13 0	<1 0	43 5	565 5
90	12 0	0 0	34 5	414 0
120	6 0	0 0	26 5	159 0
150	19 0	<1 0	25 2	479 0
180	22 5	0 0	26 0	585 0
210	22 0	0 0	21 4	471 0
240	16 0	0 0	27 0	432 0
270	19 0	0 0	24 5	465 0
300	12 0	0 0	23 5	282 0

samples immediately following the meal, followed by a decline Later, the elastase concentration again rose and finally returned toward the fasting level

To our knowledge, this is the first instance that elastase activity has been demonstrated in human pancreatic secretion Further studies are in progress to relate and quantify the relationship of elastase secretion with that of trypsin and amylase

Detoxification of Heartwood Toxins and Chlorophenols by Higher Fungi

THE heartwood of many conifers and of some broadleaved trees is well protected against attack by fungi and insects by specific and very toxic heartwood-toxins such as pinosylvin, pinosylvin-monomethylether (PSM), thujaplicins (TH), nootkatin, etc [1] These compounds have proved to be uncoupling toxins which inhibit oxidative phosphorylation in aerobic organisms[2] They have in this respect the same effect as the synthetic poisons 2,4-dinitrophenol, pentachlorophenol and other chlorinated phenols which are used for technical impregnation of less-durable timbers and of the sapwood of conifers[3] PSM has, besides its main function, a strong activity towards SH-groups of several enzymes[4]

In spite of the toxicity of these compounds it is a well-known fact that several fungi are able to destroy the heartwood even in the living tree and that impregnated timber is destroyed after some time by wood-rotting fungi There is no reason for believing that the heartwood-rotting fungi are insensitive to the heartwood toxins, because their respiration is bound to the cytochrome system and oxidative phosphorylation is the main source of energy

My most recent investigations show that pinosylvin-mono-methylether and β-thujaplicin as well as the chlorophenols lose their toxicity after oxidation by fungal oxidases such as laccase, tyrosinase and peroxidase This is shown in Table 1 by the amount of secretion of inorganic phosphate in the yeast test under the influence of the toxins before and after an oxidation with laccase The other oxidases gave similar results Tyrosinase was even more active because it oxidizes monophenols more easily

Table 1 DETOXIFICATION OF CHLOROPHENOLS AND HEARTWOOD TOXINS AFTER OXIDATION WITH LACCASE

Measured by ability to uncouple oxidative phosphorylation (secretion of inorganic phosphate (μgm P/100 ml) in the yeast test (ref 2))

Compounds	2-CP		3-CP		4-CP		5-CP		PSM		β-TH	
	Days of oxidation											
Conc (mole)	0	10	0	9	0	9	0	9	0	3	0	3
10^{-4}	350	100	350	50	400	50	200	50	—	—	—	–
3×10^{-5}	300	100	350	50	400	50	250	50	400	100	350	0
10^{-5}	250	50	250	50	350	50	350	50	350	0	250	0
3×10^{-6}	150	0	200	0	250	0	250	0	300	0	200	0
10^{-6}	100	0	150	0	200	0	200	0	250	0	100	0
3×10^{-7}	0	0	0	0	50	0	50	0	150	0	50	0
10^{-7}	0	0	0	0	0	0	0	0	50	0	0	0

No acids have been found by paper chromatography, pointing to a ring cleavage. Detoxification is nearly complete after 72 hr in β-TH Characteristic changes in the ultra-violet spectrum of the compounds, which after some time are no longer reversible by reduction, show the change of the compounds due to oxidation Its nature is not yet clear In some cases a weak polymerization is probable The chlorinated phenols split off 6 per cent (pentachlorophenol (5-CP)), 11 per cent (2,3,4,6-tetrachlorophenol (4-CP)), 18 per cent (2,4,5-trichlorophenol (3-CP)) and 43 per cent (2,4-dichlorophenol (2-CP)) respectively of the bound chlorine after 14 days incubation with laccase or peroxidase plus hydrogen peroxide

Although heartwood toxins and chlorophenols are almost of equal toxicity in the yeast test, their stability against oxidative degradation is very different This may be estimated in relative values as follows 5-chlorophenol = 100, 4-chlorophenol = 95, 3-chlorophenol = 86, 2-chlorophenol = 60, PSM = 20, β-TH = 15 This stability against detoxification is a very important factor of quality for those toxins which were not yet recognized

Nearly all heartwood-rotting fungi possess one or more of these oxidases, and it seems reasonable to assume that they are active *in vivo* too, although here a ring cleavage as the second step of degradation is to be expected This would mean a new function for the oxidases, which must be regarded as multifunctional enzymes That does not hinder the participation of the ectoenzymes laccase and peroxidase in destruction of lignin For white-rotting fungi living in the heartwood the peroxidase system is more suitable for oxidations because it does not compete for oxygen with intracellular substrate-oxidations Tyrosinase may be found in nearly all brown-rotting fungi attacking the heartwood[5]

The tannins of the heartwood strongly inhibit oxidases[4] This may be a more important function of these compounds than their low toxicity against micro-organisms This fits well with the decrease of toxicity of the heartwood components after autoxidative polymerization of tannins in aged heartwood[6,7]

The enzymatic detoxification of phenolic toxins by fungal oxidases is important in the problem of heartwood destruction by fungi and shows some causal relations in ecological specialization Whether still other mechanisms of detoxification are involved will be investigated

PHYSIOLOGY

Relationship between Changes in Muscle Volume and Muscle Action Potential

THE method which was developed for measuring small rapid changes in volume occurring in a muscle during a single twitch[1] has been applied to the case of a frog sartorius muscle immersed in hypertonic Ringer's solution As reported by various authors, one of the principal effects of hypertonic Ringer's solution on a muscle is to eliminate the twitch tension on stimulation, but not to interfere with the propagation of the muscle action potential This provides a method of determining whether or not the previously reported muscle volume changes are a direct consequence of the action potential and are thus not connected with contraction as such

The method used to measure these volume changes has been described elsewhere[2] In this experiment, the same method was used except, after determining the changes in volume in normal Ringer's solution, hypertonic Ringer's solution (2 5 times the regular concentration) was added to the muscle chamber Since this addition took approximately 30 sec , the changes in volume were not measured until this point Thirty seconds after the addition of the 2 5 Ringer's solution the muscle was stimulated by a single stimulus and the volume changes recorded

After the addition of hypertonic Ringer's solution to the muscle, the magnitude of the tension slowly decreases In addition to the decrease in magnitude of tension, the rate of development of tension is greatly prolonged After the muscle has been in the hypertonic Ringer's solution for approximately 15 min , no tension can be developed on twitch stimulation Paralleling these changes in tension, the changes in volume slowly decrease in magnitude and increase in duration, as does the twitch tension After 15 min , when the twitch tension has been reduced to zero, the changes in volume are not detectable Both the previously reported increase in volume and the decrease in volume are no longer visible This effect is completely reversible If normal Ringer's solution is then added in place of the hypertonic Ringer's solution the changes in volume and the twitch tension return to normal within a few minutes All these experiments have been carried out at 20° C

These results indicate that the changes in volume relate to contraction in a muscle, and are not directly the result of the propagation of the action potential Previously, it has been postulated that the increase in volume may be an indication of the process linking excitation to contraction in the muscle Evidence has been presented by Hill (1957) indicating that, in hypertonic Ringer's solution, the activation heat is still present It must be pointed out that in order to obtain this activation heat one needs to stimulate the muscle with ten times the normal stimulus In the measurement of changes in volume this is not possible, since this quantity of stimulus would produce a change in volume due to heating

This work has demonstrated the close correlation between both the increase in volume and the decrease in volume and the actual contraction of the muscle It may be postulated that the changes in volume are a direct indication of the protein reorganization which occurs during the contraction of a muscle It must be emphasized that the action potential does not in itself appear to be responsible for any of the observed changes in volume which occur during a single twitch of a frog sartorius muscle

Influence of Various Stimuli on Lactic Acid, Alanine and Gamma-Aminobutyric Acid Levels in Rat Brains

As has previously been shown[1,2], an increase of lactic acid, alanine and γ-aminobutyric acid in the brain of rats occurred when, after tying both carotids, stimuli were applied to the cortex which caused electroencephalographic depression This communication is concerned with the way in which the aforementioned metabolites are influenced after stimuli causing depression (3 and 0 3 *M* solutions of potassium chloride, rubidium chloride, cæsium chloride and ammonium chloride), after stimuli not causing depression (3 and 0 3 *M* solutions of lithium chloride and sodium chloride), after stimuli blocking the spreading of the depression (3 and 0 3 *M* solutions of magnesium chloride and calcium chloride[3]) and after stimuli causing the increased activity of the nervous system (1 and 10 per cent solutions of pentamethylentetrazol and 0 1 and 1 per cent solutions of strychnine), when both carotids were tied All stimuli were applied on the exposed cortex by placing a piece of filter paper dipped in the used solution on the cortex for 30 min The brains were then fixed in liquid air In ethanol extracts of the frozen brains the free amino-acids were determined by paper chromatography according to the method of Rindi and Ferrari[4] and in trichloroacetic acid extracts lactic acid was estimated according to the method of Barker and Summerson[5] All results are expressed as µmoles of the compound investigated per gram of protein nitrogen, which was determined by the micro-Kjeldahl distillation method For statistical evaluation Student's *t* test, unpaired variates, was used

As it was established that no differences could be found in the investigated metabolites between the experimental and the opposite intact hemispheres of the same amine, the latter were used as controls

The results showed that the 3 *M* chlorides of the alkali metals caused an increase of lactic acid alanine and γ-aminobutyric acid (Table 1) When 0 3 *M* solutions of the same compounds were applied, the increase of lactic acid, alanine and γ-aminobutyric acid occurred only after the solutions causing electroencephalographic depression, namely, chlorides of

potassium, rubidium, cæsium and ammonium (Table 2)

All these changes were reversed when the blood supply to the brain cortex was renewed (Table 3)

3 M solutions of chlorides of the alkali earths caused similar changes of the metabolites like 3 M solutions of the alkali metals When 3 M magnesium chloride was used, an increase of lactic acid from 138 ± 36 to 273 ± 41, alanine from 53 ± 4 to 71 ± 13 and γ-aminobutyric acid from 101 ± 10 to 126 ± 29 μmoles per gram of protein nitrogen was observed In the same way 3 M calcium chloride solution caused an increase of lactic acid from 146 ± 32 to 281 ± 58, alanine from 52 ± 5 to 71 ± 17 and γ-aminobutyric acid from 100 ± 25 to 157 ± 38 μmoles per gram of protein nitrogen (mean of 6 experiments) 0 3 M solutions neither of magnesium chloride nor of calcium chloride influenced the level of the metabolites in the brain

When 1 per cent strychnine solution was applied to the cortex, an increase of lactic acid from 97 to 342, alanine from 51 to 96 and γ-aminobutyric acid from 107 to 140 μmoles per gram of protein nitrogen was observed 10 per cent solution of pentamethylentetrazol caused an increase of lactic acid from 136 to 334, alanine from 52 to 81 and γ-aminobutyric acid from 111 to 146 μmoles per gram of protein nitrogen All changes are of statistical significance

Neither 1 per cent pentamethylentetrazol nor 0 1 per cent strychnine solutions influenced the level of the metabolites

0 15 M lactic acid solution caused an increase of alanine from 52 ± 7 to 82 ± 11 and that of γ-aminobutyric acid from 97 ± 9 to 134 ± 26 μmoles per gram of protein nitrogen

The increased alanine production during oligæmia of the brain, as has been shown previously[2,6], is related to the utilization of the free amino-acids in metabolic processes and to the increased amination of pyruvates produced during enhanced glycolysis Increased glycolysis and the decrease of pH can change the balance between the glutamic acid decarboxylase and γ-aminobutyric acid transaminase so that the predominance of decarboxylase is reached[7] and more

γ-aminobutyric acid can be produced Together with this phenomenon a decrease of α-ketoglutarate during oligæmia of the brain can be expected and so the transamination of γ-aminobutyric acid slowed down owing to lack of the substrate With respect to the increased formation of γ-aminobutyric acid and its decreased transamination the increased level of γ-aminobutyric acid in the experimental hemispheres was found

The increase of lactic acid, alanine and γ-aminobutyric acid is accompanied by some changes in the structure of the nerve cells The sections of the brain cortex after stimulation showed vacuolization and chromatolysis of the cytoplasm, thickening of the nuclear membrane, shrinking of the nuclear chromatin and the disintegration of the nucleolus[8] Therefore it is supposed that the metabolic reactions described are not only due to the altered functional activity of the nerve elements (that is, electroencephalographic depression, stimulation with pentamethylentetrazol and strychnine), but also to the rebuilding of the damaged cell structures

Starvation and Renal Uptake of Vitamin B_{12}

Rosenthal and Cravitz have reported[1-3] that rabbits subjected to starvation accumulated remarkably large amounts of vitamin B_{12} in the kidney as compared with normally fed controls They also found similar, but less pronounced, effects of starvation in some animal species. No satisfactory explanation has been offered, however Our investigations with rats demonstrated that the renal uptake of vitamin B_{12} labelled with cobalt-60 following an oral administration was much greater in animals which had received vitamin B_{12} in their diet than in those which had been deprived of it[4] This finding together with other results[5] strongly suggest that the kidney is a kind of storage organ of vitamin B_{12}, and that accumulation of the vitamin in this organ is indication of a highly saturated state of the body tissue with respect to vitamin B_{12} In view of the discrepancy between Rosenthal's and our findings, the starvation experiment described in his recent paper[3] was followed, except that a special measure was taken for the prevention of coprophagy

Female rabbits weighing about 2 kgm were housed in individual cages with a wide screen bottom They were divided into 6 groups, 3 animals in each Three control groups (*A*, *B* and *C*) were fed *ad lib* with fresh and dried green vegetables and soybean-curd (Okara) for 6 days and then given labelled vitamin B_{12} by intramuscular injection, 0 05 μgm (0 04 μc)/kgm body-weight After the injection, group *A* was fed continuously, groups *B* and *C* were fasted, and all were killed 3 days later During the fasting period, each animal in group *C* was kept in a metal cylinder-type rabbit holder in the daytime and was released for the night The holder kept the animal in a stretched position, preventing it from reaching the fæces The three starved groups (*D*, *E* and *F*) were given no food for 6 days, the same dose of labelled vitamin B_{12} was injected, and the animals were fasted for 3 more days before death Groups *D* and *F* were kept in the holder during the night, and group *E* was kept in the holder during the daytime Group *F* received, besides, 3 doses of 1 mgm vitamin B_{12} by subcutaneous injection every other day during the pre-injection period At the end of 3 days after the administration of labelled vitamin B_{12}, the liver and the kidneys were removed, a portion of the former and all the latter were digested with 30 per cent potassium hydroxide and the radioactivities measured using the technique already described[6] The uptake of cobalt-60 by these organs expressed as a percentage of the dose per wet gram tissue is presented in Fig 1 It is evident that group *D*, which was fasted without having access to the fæces during the night, retained considerably less radioactivity in the kidneys as compared with other groups The kidneys of groups *E* and *F*, which were fasted but had access to the night fæces or received vitamin B_{12} by injection, accumulated more cobalt-60 Thus, the effect of starvation in rabbits with controlled coprophagy was quite contrary to that obtained without such a measure

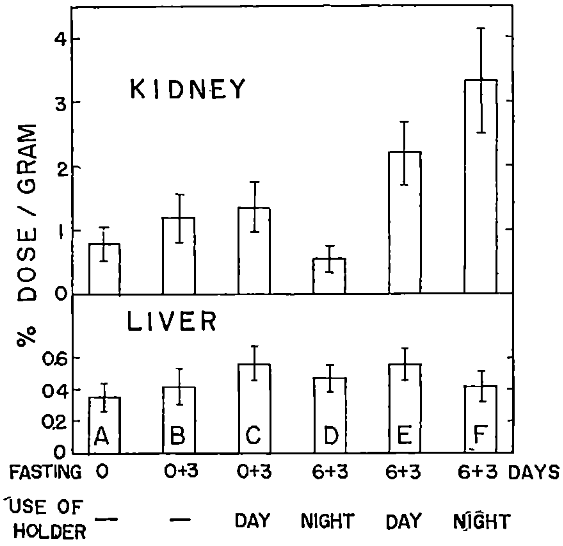

Fig 1 The effect of starvation on tissue uptake of injected vitamin B_{12} labelled with cobalt-60 in rabbits The vertical bars represent *S E* The numbers before and after (+) indicate days of fasting before and after the administration of labelled vitamin B_{12} Animals were killed three days after the injection of labelled vitamin B_{12}

Southern[7] and Eden[8] have observed that the rabbit voids soft fæces during the night which are consumed as they are excreted Kulwich[9] collected the soft fæces for three days by fitting a collar to the rabbit to prevent coprophagy, and found that the fæces

Table 1 EFFECTS OF STARVATION AND VITAMIN B_{12} ADMINISTRATION ON TISSUE DISTRIBUTION OF VITAMIN B_{12} LABELLED WITH COBALT-60 IN RATS

Group	Liver (per cent/organ)	Kidneys (per cent/organ)
(*A*) Non-fasted	13 ± 1 2	14 ± 1 5
(*B*) Non-fasted + B_{12}*	7 ± 0 8	41 ± 3 6
(*C*) Fasted	15 ± 1 4	11 ± 0 9
(*D*) Fasted + B_{12}*	6 ± 0 8	39 ± 4 2

Animals were killed three days after the administration of 20 mμgm of labelled vitamin B_{12} intraperitoneally

* Three doses of 50 μgm were given subcutaneously prior to labelled vitamin B_{12} Each figure is average of three rats ± *S E*

made a significant contribution to the vitamin economy of the animal. It seems that this characteristic behaviour is responsible for the exceptionally high contents of vitamin B_{12} in the rabbit[10]. Recently, Hirabayashi *et al.*[11] have demonstrated, using the collar technique, that normally the soft fæces voided during the night are completely consumed and that the mucous film separated from such fæces is an almost pure mucoprotein-B_{12} complex. According to Y. Sahashi (personal communication), use of a screen bottom is of little value and even the collar does not afford absolute arrest of coprophagy.

It may be that restricting food without a special measure for absolute prevention of coprophagy will simply increase coprophagic activities of the rabbit, and will result in a greater intake and therefore accumulation of vitamin B_{12} in the kidney. The uptake of a test dose of vitamin B_{12} labelled with cobalt-60 by the kidney depends more on the amount of vitamin B_{12} than food taken prior to the test. This fact is also clearly borne out in rats by the following experiment. Twelve young adult male rats which had been raised on a stock diet were placed in individual cages with a screen bottom, and were divided into 4 groups. Two groups (*A* and *B*) were fed *ad lib.* the same diet and the other two (*C* and *D*) were fasted for 5 days. Groups *B* and *D* received 50 μgm. of vitamin B_{12} by injection daily for the first 3 days. All animals were given 20 μgm. of labelled vitamin B_{12} intraperitoneally at the end of the 5th day. They were either fed continuously (*A* and *B*) or fasted (*C* and *D*) for 3 more days after the administration of labelled vitamin B_{12} and then killed. The amounts of cobalt-60 measured in the liver and the kidneys (Table 1) demonstrate that the uptake of cobalt-60 (most likely as the labelled vitamin B_{12}) by the kidney reflects the preceding intake of vitamin B_{12} rather than the amount of food fed.

Initiation of Anaerobic Metabolism of Mammalian Spermatozoa by Carbon Dioxide

LITTLE is known about the effect of the absence of carbon dioxide on the metabolism of spermatozoa. In 1930 Harvey[1] suggested that the inability of *Arbacia punctulata* spermatozoa to survive during a 4-hr. incubation period in an atmosphere of hydrogen might be due to the absence of carbon dioxide. To our knowledge this suggestion has not been investigated nor has a similar observation and suggestion been reported for mammalian spermatozoa.

The beneficial use of diluters containing carbon dioxide to lengthen the *in vitro* survival of bovine spermatozoa has been demonstrated[2,3]. The increased survival presumably is due to the fact that anaerobic glycolysis[4,5] and the motility[6,7] of mammalian spermatozoa are markedly inhibited by relatively high $p\mathrm{CO}_2$. On the other hand, respiration[8,9] and aerobic glycolysis[10] of spermatozoa have been reported to be stimulated by low $p\mathrm{CO}_2$. In our work[9], it was observed that with some washed spermatozoan samples there was less carbon dioxide present in the flasks after 1 or 2 hr. of incubation than was present initially. Although earlier work has suggested an involvement of carbon dioxide in spermatozoan metabolism and survival, an actual need for carbon dioxide for these responses has not been reported. This communication reports results of an investigation implicating carbon dioxide as a necessary factor in initiating anaerobic glycolysis and for extending the *in vitro* survival time of bovine spermatozoa.

The anaerobic metabolism of epididymal-like spermatozoa[11] diluted in a sodium citrate, sodium bicarbonate (IVT) diluent[4] containing fructose was studied under gaseous atmospheres of 100 per cent nitrogen, 5 per cent carbon dioxide + 95 per cent nitrogen, and 100 per cent carbon dioxide in a Warburg respirometer at 37° C for 4 hr. Epididymal-like spermatozoa are obtained by collecting semen into an inhibitory diluent which renders the sperm cells non-motile and prevents the uptake of exogenous substrates from seminal plasma. The sperm cells are washed free of inhibitory diluent and re-suspended in 0.9 per cent sodium chloride solution to the original volume of the semen sample. The carbon dioxide evolved by the reaction of metabolically produced acid with bicarbonate (corrected for acid and carbon dioxide retention), the fructose disappearance, the lactic acid accumulation, and the recovery of motility on exposure to air were used as criteria of measurement. The methods of analysis have been reported previously[10].

The results presented in Table 1 show that of 59 spermatozoan samples examined the response to 100 per cent nitrogen could be divided into two distinct groups. The one group including 49 samples demonstrated little if any glycolytic activity, whereas the other group of 10 samples demonstrated substantial glycolytic activity under the nitrogen atmosphere.

Spermatozoa from the same 49 samples not metabolizing under nitrogen demonstrated normal glycolytic activity in a nitrogen atmosphere containing 5 per cent carbon dioxide. When the $p\mathrm{CO}_2$ was increased to 100 per cent, glycolysis by the sperm cells was markedly inhibited and was similar to that of the sperm cells under pure nitrogen. Although there was essentially no glycolysis occurring under both pure nitrogen and pure carbon dioxide in these 49 samples the recovery of motility on exposure to air, as determined by microscopic examination at the end of the 4-hr. incubation period, was markedly improved by the presence of carbon dioxide in the incubation atmosphere. There was essentially no sperm cell motility observed in samples which had been incubated under nitrogen, in contrast to good recovery of sperm cell motility in samples incubated under 100 per cent carbon dioxide (Table 1).

As already stated, substantial glycolysis did occur under 100 per cent nitrogen in 10 of the 59 samples studied, but even in these samples there was a stimulation of glycolysis when 5 per cent carbon dioxide was included in the gaseous atmosphere. It should be noted that these 10 spermatozoan samples contained more spermatozoa per unit volume than

Table 1 EFFECT OF CARBON DIOXIDE ON THE ANAEROBIC METABOLISM OF EPIDIDYMAL-LIKE BOVINE SPERMATOZOA IN A CITRATE–BICARBONATE MEDIUM CONTAINING FRUCTOSE AND THE RECOVERY OF MOTILITY ON EXPOSURE TO AIR AFTER INCUBATION

Diluent	n	Sperm conc × 10^8	Gas	CO_2* evolved	−Fructose*	+L A *	Motility † (per cent)
IVT	49	2 162	100% N_2	8 6	38 1	40 7	0 8
			5% CO_2+95% N_2	139 6	715 7	417 8	30 0
			100% CO_2	8 6	29 3	62 2	38 0
IVT	10	3 543	100% N_2	110 4	430 4	268 3	17 0
			5% CO_2+95% N_2	132 9	723 4	437 2	37 0
			100% CO_2	16 7	178 9	23 8	42 0

* μl or μgm /10^8/4 hr
† Mean initial percentage motility was 50 and 57 for the 49 and 10 samples respectively

did the 49 samples which did not metabolize under nitrogen Even in these more concentrated samples glycolysis was markedly inhibited by 100 per cent carbon dioxide Although some motility was observed on aeration at the end of the incubation period in these samples metabolizing under nitrogen, the percentage of motile spermatozoa was much greater after incubation in the carbon dioxide atmosphere The reason for glycolysis occurring in 10 samples under nitrogen in contrast to the lack of it in 49 samples is not known, but it is suspected that due to the relatively higher sperm cell concentration enough carbon dioxide was retained by the spermatozoa to initiate glycolysis and maintain motility It was observed that in flasks containing a sperm cell concentration above 4 0 × 10^8 spermatozoa per ml glycolysis did occur under nitrogen, and in flasks containing less than 2 0 × 10^8 spermatozoa per ml glycolysis did not occur With sperm cell concentrations between 2 0 and 4 0 × 10^8 spermatozoa in the flasks the results were not predictable in that some samples did glycolyse and some did not

The results presented here are the first to show an apparent need for carbon dioxide in the metabolism and survival of spermatozoa and investigations are being continued to determine the exact part which carbon dioxide plays in the metabolic process

Effect of Ouabain on the Resting Tension and the Rate of Net Entry of Calcium-45 in Isolated Perfused Rabbit Ventricles

RECENT work in this laboratory has shown that in isolated rabbit atria the contracture induced by ouabain is probably the result of an increased calcium uptake[1] Furthermore, it was shown that ouabain only affected calcium exchange that accompanies the process of activation[2] Temperature studies revealed a high temperature coefficient (Q_{10}) of 4–6 for both the effects on contracture and calcium-45 entry[3] In this report we present the effects of ouabain on entry of calcium-45 and contracture in isolated perfused rabbit ventricles The results indicate that contractures induced by the cardiac glycosides in both rabbit atria and ventricles are associated with an increased calcium entry

Young rabbits were used Hearts freshly excised were perfused through a cannula in the ascending aorta, the normal perfusion fluid containing sodium chloride 7 7 gm , potassium chloride, 0 42 gm , calcium chloride, 0 24 gm , sodium bicarbonate, 2 1 gm , crystalline sodium dihydrogen phosphate, 0 143 gm , dextrose, 2 0 gm , sucrose, 4 5 gm , distilled water to 1 litre The solution was saturated with 95 per cent oxygen and 5 per cent carbon dioxide Perfusion was performed by means of a special apparatus in which the temperature of the solution entering the heart could be kept constant at 37° C , regardless of the perfusion-rate Tension changes were recorded on a Sanborn twin-channel recorder using a strain gauge by means of a thread attached to the tip of the left ventricle

The rate of net entry of calcium-45 was determined by perfusing the heart with the isotope and with and without ouabain (10^{-6} M) for 25 min This was followed by perfusion with non-radioactive solution for 5 min The ventricular tissue was then dried, weighed and homogenized in distilled water The total radioactivity of an aliquot of this solution was determined and the rate of net entry of calcium-45 calculated

Table 1 shows the effects of ouabain on both the rate of net entry of calcium-45 in c p m /gm of ventricular tissue and the percentage increase in resting tension Both the mean and individual paired experiments done simultaneously are presented Ouabain significantly increased the mean rate of net entry of calcium-45 116 per cent ($P < 0\ 02$) In addition ouabain increased the mean resting tension 45 per cent In experiment seven only a positive inotropic effect was recorded It is interesting to note that in this experiment there was an 11 per cent increase in the net rate of entry of calcium-

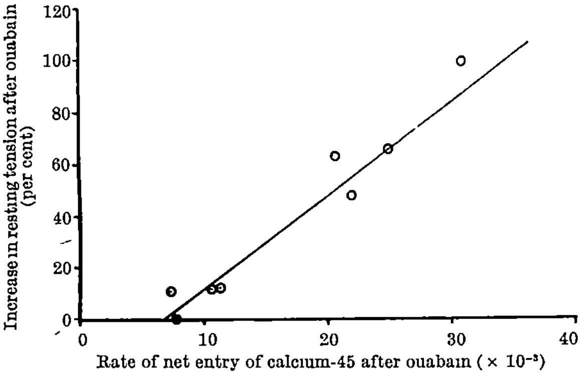

Fig 1 Relation between changes in resting tension and the rate of net entry of calcium-45 after treatment with ouabain (10^{-6} *M*)

45 in the ouabain-treated heart when compared with its paired control However, there was no significant difference when compared with the mean control value

In Fig 1 we have attempted to correlate changes in resting tension with the rate of net entry of calcium-45 in each individual heart after ouabain It can be seen that there is an essentially good positive correlation between resting tension at 20 min and the rate of net entry of calcium-45

Thomas indicates that the contractures induced by ouabain in frog hearts are associated with an increased uptake of calcium-45 (ref 4) However, in his experiments there was only a slight correlation between the changes in resting tension and uptake of calcium-45 In addition, the percentage changes in uptake of calcium-45 were small (25 per cent) In our experiment a good positive correlation was obtained between the increase in resting tension and the rate of net entry of calcium-45 Furthermore, the increase of the rate of entry of calcium-45 was large (116 per cent) These differences could be due to several factors In our experiments we used a wash-out period in non-radioactive solution in order to decrease extracellular calcium-45 and accentuate cellular changes In addition, our experiments were carried out at 37° C as compared with 21°–24° C Recent investigations in this laboratory indicate that the contracture and increased entry of calcium-45 induced by ouabain are both temperature-sensitive (Q_{10}s of 4–6)

Since calcium-45 efflux measurements were not attempted, the net effect of calcium could not be determined However, studies in several laboratories of both skeletal and heart muscle have revealed that ouabain has no effect on calcium outflow[1,5] In addition, Lee has demonstrated an actual net increase of cellular calcium during ouabain intoxication in the papillary muscle of the cat[6]

These results indicate that the ouabain-induced contractures in both rabbit atria and ventricles are basically similar and probably result from increased calcium concentration in the cardiac cell

The exact mechanism by which this increased concentration of calcium in the myoplasm results in contracture is not known Evidence obtained from isolated fibre systems indicates that calcium is the only physiological ion which causes contraction when injected directly into the myoplasm[7] However, in isolated glycerol-extracted fibres calcium does not cause contraction unless relaxing factor or factors are present and active[8] This suggests that under physiological conditions ouabain-induced contractures could result from an inhibition of relaxing factor(s) due to an increased concentration of calcium in the vicinity of the contractile apparatus

Investigations in this laboratory are now in progress to determine in what sub-cellular fraction(s) this increased calcium is located and also whether ouabain has any direct effect on calcium metabolism in these fractions

PHARMACOLOGY

Effect of Salicylate on Plasma Magnesium-Levels

In this laboratory a recent examination of the distribution of electrolytes in rats following the repeated administration of both sodium and potassium salicylate has shown that a marked decrease in the excretion of urinary magnesium occurs Evidence of a less well-defined increase in the level of plasma magnesium was also found[1]

To examine this point in greater detail, plasma was collected from a group of 23 untreated laboratory rats and from 13 animals which had been given either sodium or potassium salicylate by gavage for at least seven days The drug was given as an aqueous solution in a dosage of 30 mgm salicylate radical/100 mgm body-weight/day All the treated rats exhibited clear symptoms of salicylate intoxication prior to the collection of blood samples, that is, hyperventilation, body wastage and hæmorrhage Heparinized blood was collected within 30 min of administration of the drug in order to obtain near maximum levels of plasma salicylate[2]

Plasma magnesium was estimated by the method of Orange and Rhein[3] and salicylate by Trinder's method[4]

It can be seen from the results in Table 1 that there is a substantial elevation in the plasma magnesium-levels of those rats receiving salicylate (mean 3 7 mgm per cent *SD* ± 0 23 mgm per cent) compared

Table 1 EFFECT OF SALICYLATE ON PLASMA MAGNESIUM-LEVELS IN THE RAT

Group	No	Plasma constituent	Mgm (per cent)					Mean
Control	23	Mg++	2 1	2 7	2 3	2 4	3 0	
			2 8	3 0	3 3	3 0	3 1	
			2 6	2 9	3 0	3 3	3 2	2 9
			3 0	3 1	3 2	3 3	2 4	
			2 9	2 9	2 8			
		Salicylate	—					
Treated	13	Mg++	3 0	3 8	3 1	3 8	4 6	
			4 2	4 0	4 5	3 1	3 2	3 7
			4 3	3 9	2 9			
		Salicylate	39	23	52	48	82	
			58	65	40	33	45	51
			56	56	75			

Salicylate given as the sodium or potassium salt by gavage in dosage of 30 mgm /100 gm body-weight/day for at least seven days with the levels estimated in the untreated group (mean 2 9 mgm per cent *S D* ± 0 63 mgm per cent) By calculating a common variance, comparison of the mean values for each group reveals a significant difference at the 0 1 per cent level The elevated plasma magnesium-level in the treated group is associated with a mean plasma salicylate-level of 51 mgm per cent (*S D* ± 16 8 mgm per cent)

Taken with the finding of decreased excretion of Mg^{++} under similar conditions of intoxication[1] it is apparent that a retention of magnesium ions is produced by the administration of salicylate

Since the early observations of Winter and Barbour[5] magnesium has been used both experimentally and clinically to reduce body temperature under a wide variety of conditions[6] The rise in plasma magnesium which is associated with high plasma salicylate-levels may therefore explain the antipyretic effect of this drug

Protective Action of γ-Aminobutyric Acid against Oxygen Toxicity

The effects of the inhalation of oxygen at greater than normal pressures have assumed greater importance as man's penetration into the depths of the sea has increased It was Bert[1] who for the first time revealed that, although oxygen at low pressures sustains life, the gas is toxic at high pressures In their review of the subject, Stadie *et al* [2] conclude that the dominant symptoms of the action of oxygen at 0 8–2 0 atmospheres are respiratory, while at higher oxygen pressures central nervous system symptoms predominate Several theories have been put forward to explain the toxic effects of oxygen at high pressures[3], but no one theory is completely satisfactory

Of the animal tissues and fluids which have been examined for γ-aminobutyric acid (GABA), only those from the central nervous system contain the amino-acid in detectable amounts[4], and it has been suggested that GABA may play an important part in some aspects of the regulation of physiological activity in the brain[5] More recent investigations have indicated that treatment of animals with GABA affords some protection against convulsions induced by hydrazides[6] and that human beings with various types of seizures experience significant improvement in their condition as a result of treatment with oral doses of GABA[7]

In view of these findings it was deemed worth while to investigate the influence of GABA on the toxic effects of oxygen at high pressures The results of this investigation are presented here

Table 1 EFFECT OF AN ORAL DOSE OF γ-AMINOBUTYRIC ACID ON THE RESISTANCE OF RATS TO OXYGEN TOXICITY

* Probability that difference from control rats is significant, P < 0 01

† Probability that difference from control rats is significant, P < 0 001

Male Wistar rats weighing 190–220 gm were used in the experiments Two ml of 0 9 per cent aqueous sodium chloride containing 2 m moles of GABA were injected intraperitoneally 30 min prior to exposure of the animals to oxygen at high pressure Control rats were treated similarly except that the GABA was omitted from the saline solution Three control and three treated rats were studied simultaneously using the procedure of Walker[8], which entails placing the animals in lucite compartments contained in a pressure chamber After the apparatus had been flushed well with oxygen for approximately 1 min the pressure was increased steadily during a 1-min interval to a gauge pressure of 75 lb /in [2] This pressure was maintained for 40 min followed by decompression to atmospheric pressure over a period of 2 min During the exposure to oxygen at high pressure a fan outside the pressure chamber circulated the oxygen and passed the respired gas through a screen of soda-lime to remove the carbon dioxide exhaled by the animals

The effect of oxygen at high pressure on control and GABA-treated animals is shown in Table 1 A convulsion was scored when an involuntary movement of the body occurred and the seizure was considered to be severe when there was gross and violent movement of the body as a whole It is evident that GABA reduced significantly the effects of oxygen at high pressure on the treated rats, not only in the number of deaths resulting from oxygen at high pressure but also in the number and severity of the convulsions Of the control rats having seizures, 53 per cent suffered violent convulsions whereas the corresponding figure for the treated rats was 24 per cent

HÆMATOLOGY

Acid Phosphatase Activity in Human Blood Cells

An improved azo dye method[1] has been applied to human blood cells by which acid phosphatase activity could be demonstrated in all peripheral leucocytes and platelets. This technique is based on the use of phosphate esters of 'Naphthol *AS*' derivatives[2] as substrates and hexazonium *p*-rosanilin as a coupler[3,4].

Blood smears, air-dried for 10–20 min. at room temperature, were fixed for 10 min. in cold (4° C.) 10 per cent formalin containing 1 per cent calcium chloride. The formalin solution was adjusted to *p*H 7.0 with *N* sodium hydroxide and controlled weekly. (A 10 per cent formalin solution in 0.1 *M* sodium acetate adjusted to *p*H 7.0 can be substituted with similar results.) Following fixation, the smears were rinsed well with distilled water and incubated for up to 3 hr. (generally 2 hr.) at room temperature. The incubation time can be reduced to about half with similar results by incubating at 37° C. The incubation solution was freshly prepared from four stock solutions: (1) Michaelis veronal–acetate buffer stock solution: 9.71 gm. sodium acetate. $3H_2O$ plus 14.71 gm. sodium barbiturate dissolved in carbon dioxide free distilled water made up to final volume of 500 ml. (2) Substrate stock solution: 'Naphthol *AS–BI*' phosphate (Nutritional Biochemical Co., Cleveland, Ohio) dissolved in *N*,*N*-dimethyl-formamide in 10 mgm./ml. concentration. (3) 4 per cent sodium nitrite in distilled water. (4) 2 gm. 'Pararosanilin-hydrochloride' (National Aniline Division, Allied Chemical and Dye Corporation, New York) added to 50 ml. 2 *N* hydrochloric acid and gently heated. After cooling, the solution was filtered. Solutions 1, 2 and 3 were stored at 4° C. The working solution was prepared as follows: 5 ml. of solution No. 1 and 1 ml. of No. 2 were mixed with 13 ml. of distilled water in a beaker. To this was added 1.6 ml. of hexazonium *p*-rosanilin solution obtained by adding 0.8 ml. of solution No. 3 to 0.8 ml. of solution No. 4 in a test tube. After mixing, the *p*H was adjusted to 5.0 with *N* sodium hydroxide.

Following the incubation, the smears were rinsed in distilled water and counterstained with methyl green (1 per cent methyl green in phosphate or veronal–acetate buffer, *p*H 4) for 30–60 sec., rinsed well in distilled water, quickly dehydrated through alcohol and mounted via xylene in synthetic mounting medium. The sites of enzyme activity were marked by deposits of amorphous red azo dye. (The microscopic observation of the red azo dye precipitate is facilitated by using a balanced light source obtained by combining a didymium and Wratten 82 *C* filter.) The nuclei were stained green.

During the incubation period some precipitate developed in the test medium. Nevertheless, changing the solution midway during the incubation produced no improvement in the staining reaction. Acid phosphatase activity could be demonstrated in cells in unfixed smears. The fixation used, however, improved the morphological preservation of the cells. From the point of view of both morphology and preservation of enzyme activity neutral formalin was found to be the superior fixative.

Acid phosphatase activity could also be demonstrated in blood cells by using other 'Naphthol *AS*' substrates. The intensity of the staining reaction decreased with the various substrates tested in the following order: 'Naphthol *AS—BI*', '*AS—AN*', '*AS—TR*', '*AS—CL*' and '*AS—MX* phosphate'. Practically no staining occurred after a 3-hr. incubation with 'Naphthol *AS—GR*' phosphate. With these phosphate esters no substrate specificity or preferential staining was observed in the blood cells tested. α-Naphthyl phosphate with hexazonium *p*-rosanilin (1 at *p*H 6 or 6.5 sec., ref. 4) gave less satisfactory results.

After incubation for 2 hr., acid phosphatase activity was demonstrated in all types of leucocytes. Every cell showed some degree of activity. Basophiles, however, were not definitely identified. Eosinophiles and monocytes revealed the most intense reaction followed by neutrophiles and lymphocytes. Staining was also observed in platelets but not in erythrocytes. In each cell series variations of the enzyme activity were seen. The nature of the staining reaction was generally very finely granular and diffuse. However, in each of the cell series there were cells which revealed coarser granules of azo dye scattered in their cytoplasm. (The demonstration of acid phosphatase activity in human blood cells using Gomori's lead sulphide method, as well as the relationship of enzyme activity to lysosomes, was discussed elsewhere[5].) The technique reported here can be applied to bone marrow smears (for example, very high acid phosphatase activity was found in multiple myeloma cells).

Since the simple technique reported here gave reproducible and artefact-free localization, it is hoped that it will facilitate the investigation of acid phosphatase activity in both blood and bone marrow cells in various pathological conditions.

'Naphthol *AS—AN*' and '*AS—CL*' phosphates were synthesized and kindly supplied by Dr. M. S. Brustone, whom we thank.

Two Human Blood Group Antigens, St^a (Stones) and Ri^a (Ridley), closely related to the MNSs System

A series of screening tests has been undertaken with a serum Ath. known to contain powerful saline-agglutinating antibodies against the rare Wright (Wr^a) and Swann (Sw^a) blood group factors. Control reagents were prepared by absorbing separate aliquots of the serum with known Wr(a +) and Sw(a +) cells. Samples found positive with the native serum were tested afterwards with these control reagents, so that Wr(a +) and Sw(a +) individuals were readily identified.

The cells of one such positive reactor, Mrs. Stones, were found to react with both the absorbed sera, and further tests have shown that a third antibody is present in serum Ath. This is clearly separable from the other two antibodies by absorption with Mrs.

Stones's cells, thus yielding a third control reagent for subsequent tests

The propositus' cells were grouped as

A_2, cde/cde, NS/Ns, P_1 + +, Lu(a − b +), Le(a − b +), K − k +, Kp(a − b +), Fy(a + b +), Jk(a + b −)

and negative reactions were obtained with anti-V, -$\mathrm{C^x}$, -$\mathrm{Js^a}$, -$\mathrm{p^k}$, -$\mathrm{Di^a}$, -By, -$\mathrm{Be^a}$, -Good, -$\mathrm{Bi^a}$, -Levay, -$\mathrm{Mi^a}$, -Vw, -Hu, -He, -Vr, -$\mathrm{M^g}$, -Wb [1], -$\mathrm{Mt^a}$ [2], -Mu [3], -$\mathrm{Tr^a}$[4] The cells reacted strongly with anti-Vel, -Ge, -$\mathrm{Yt^a}$, -$\mathrm{Tj^a}$ (− P + P_1), -$\mathrm{Lu^b}$ and -H, and the I-i status was normal No relationship was established with some 19 assorted un-solved 'private' groups, some of which are admittedly of rather doubtful standing

It is considered that this is clear evidence of the presence of a hitherto unrecognized blood group antigen on Mrs Stones's cells It is proposed to call this $\mathrm{St^a}$ (Stones), and the gene responsible for its transmission, St^a, the antibody, anti-$\mathrm{St^a}$, recognizing phenotypes St(a +) and St(a −)

A total of 17,013 random samples, including 830 normal cord bloods, has now been tested with serum Ath , with results as follow

Wr(a+)	Sw(a+)	St(a+)	Total
16	2	20*	38

* 2 related

The frequencies for $\mathrm{Wr^a}$ and $\mathrm{Sw^a}$ are in good agreement with those previously reported by me[4,5], and support the belief that the sample was random One St(a +) propositus was identified by testing cord blood, as was 1 Wr(a +), which indicates that both these antigens are well developed at birth

A study of the families of 19 unrelated St(a +) individuals is in progress Inheritance of $\mathrm{St^a}$ is clearly that of a Mendelian dominant character, and all of 25 sibships containing St (a +) individuals have been shown to stem from the mating St(a +) × St(a −) The antigen has been demonstrated in at least 2 generations of 12 of the families tested, and in 4 generations of 3 of them

Independent segregation of St^a and the genes for the ABO, Rh, P, Lutheran, Kell, Lewis red cell-ABH secretor, Duffy and Kidd systems has been established, and sex-linkage excluded

Information on the relationship of $\mathrm{St^a}$ to the MNSs system derives from 12 matings in 10 families, and linkage appears to be very close In 39 segregations observed between St^a and the MNSs genes, there were 38 non-cross-overs and 1 cross-over ($\Sigma\lambda = +73$, $\Sigma\varkappa = 83$ $P = \gg 0\ 01$) If the apparent cross-over is accepted at face value, and there seems to be no reason for doubting its authenticity, then it would appear likely that the linkage is not of the very close type like that between D, C and E in the Rh system, but that St^a and the MNSs genes occupy closely adjacent sites on the same chromosome Considerably more family material will have to be tested before this point can be settled conclusively

The MNSs alignment of St^a has been established by family study in 12 instances, and is

MS	*Ms*	*NS*	*Ns*	Total
0	1	2	9	12

In one other family, alignment was with either *MS* or *Ms*

While this work was in progress, the presence of yet another antibody in serum Ath was established by these methods, recognizing another 'new' factor, $\mathrm{Ri^a}$ (Ridley), of great rarity, only one propositus being found in the 17,013 random samples tested His blood groups were

A_2, CDe/cde, MS/M$\bar{\mathrm{s}}$, P_1 + + +, Lu (a − b +), Le(a − b −), K − k +, Kp(a − b +), Fy(a + b +), Jk(a + b +),

results similar to those with Mrs Stones being obtained with the 'private' and 'public' antisera listed here

The family study so far has shown that the character is inherited as a Mendelian dominant, segregating independently of the ABO and Rh genes Here again, strong evidence is building up for linkage with the MNSs system, alignment being with *MS* Independence counts[6] of 3 0 and 5 0 have been obtained, as well as 2 additional single segregations with *MS* Further, in a sibship of 7 in the first generation, 4 members with *MS* are all Ri(a +) while 3 without *MS* are Ri(a −)

It is tempting to speculate on the possibility that anti-$\mathrm{St^a}$ and -$\mathrm{Ri^a}$ in serum Ath are related as are anti-$\mathrm{Mi^a}$ and -Vw in antisera of the 'Miltenberger' type[7] On the other hand, their presence together may be entirely fortuitous, as was, presumably, that of anti-$\mathrm{Wr^a}$ and -$\mathrm{Sw^a}$, which have both been excluded from any connexion with the MNSs system

HISTOCHEMISTRY

Histochemical Localization of β-Glucuronidase in Healing Wounds of the Natterjack Toad

β-Glucuronidase the enzyme related to cell proliferation and the formation of connective-tissue ground substance, has been observed in basal layers of the oral mucous membrane and the epidermis, the blood vessels of the normal derma, and healing wounds of the skin of the back, the palate and the tongue in the rat[1–3] and healing wounds of the dorsal skin and the tongue in the iguana[4] In addition to these experiments I have examined the activity of β-glucuronidase in healing wounds of the dorsal skin and the tongue in an amphibian species, the natterjack toad (*Bufo calamita*), the animals being killed by decapitation after 4, 7, 14, 21, 28, 35 and 42 days

After excision of the wound with an extensive zone of normal surrounding tissue and fixation in formalin/chloral hydrate, the enzymatic activity was determined by the method of Fishman and Baker[5] on frozen sections with different incubation times A negative reaction was obtained in the superficial necrotic band of connective tissue in the 4-day animals, whereas immediately beneath this negative zone there was an intensely positive zone due to the presence of inflammatory exudate, and particularly leucocytes As the healing progressed, the fibroblastic proliferation zone appeared to react moderately but consistently. The multinucleated giant cells and histiocytes reacted more intensely. In the 21, 28, 35 and 42-day animals the epidermis, which had proliferated over the margins of the wound, showed a significant increase in enzymatic activity.

The epithelial proliferation appears to be closely related to β-glucuronidase activity. In the connective tissue this enzyme is associated with tissue formation and macrophage function. Since these results are in good agreement with those obtained in the rat[1] and the iguana[4] the distribution of β-glucuronidase in the epidermis no doubt has wider implications.

Arrangement of Cholesterol Molecules in the Myelin Sheath

Polarized light studies[1,2] have indicated that most or all lipid moieties of the myelin sheath are radially arranged. Finean[3,4] correlated the X-ray diffraction patterns of fresh and lipid-solvent extracted myelin with known data about the form and size of lipid molecules and suggested that a phospholipid–cholesterol complex forms a part of myelin. According to this notion the long chain of the phospholipid moiety is lying radially with curling of the polar end group, so that the phosphate might serve to bind the lipid to protein, whereas the positively charged part of the molecule is closely associated with the hydroxyl group of cholesterol. The complex would have, therefore, the form of a U, with the cholesterol and the hydrocarbon chain of the phospholipid situated in a parallel fashion and in a radial direction.

In this laboratory extraction with acetone at 0° to + 4° of human peripheral nerve and of cerebral white matter yielded similar results to those reported by Elkes and Finean[5], that is, acetone at this temperature (two 1 hr. changes) extracted practically all the cholesterol and less than 10 per cent of the phospholipids. In addition it was found that cold acetone extracted no hexosamine-containing compounds and negligible amounts of cerebroside. The estimation of the amount of total extractable lipids was done by 6 hr. extraction in boiling chloroform/methanol, 2 : 1.

A comparative histochemical study was made on fresh frozen sections extracted with acetone and on control (not extracted) sections. Human corpus callosum and peripheral nerve were frozen rapidly in isopentane chilled to about – 65° and 9μ thick sections were cut in the cryostat. Acetone extraction was done as above.

Cold acetone extraction was found to have no appreciable effect on the intensity of staining with the following procedures: sudan black *B* (for total lipids), plasmal and performic acid–Schiff (for unsaturated lipids) and the periodic acid–Schiff procedure which stains mainly carbohydrates and carbohydrate-containing lipids. No staining with the Schultz procedure for cholesterol was obtained in the extracted sections. Staining by Baker's procedure for phospholipids and by the *Einschlussfaerbung* of Feyrter with toluidine blue revealed some reduction of the intensity of staining in the extracted sections. These findings indicate that cholesterol was wholly extracted, whereas the total amount of lipids and the amount of cerebrosides were not markedly affected. The reduced intensity of staining with Baker's method and the reduced metachromasia indicates that acidic phospholipids were more markedly affected by the solvent than other phospholipids. The fact that no increase in metachromasia was noted in the extracted sections supports the idea of Finean according to which the negatively charged group of the phospholipid plays no part in binding cholesterol.

The effect of cold acetone extraction on the birefringence of myelin was examined as follows:

Longitudinal and transverse cryostat sections of human peripheral nerve were mounted in glycerine (in order to minimize form birefringence) and the intensity of birefringence was determined at certain marked sites. For low intensities the Brace-Köhler compensator was used, and for high intensities the Köhler compensator. After removing the coverslip and rinsing with water to remove the glycerine, the sections were extracted with acetone as above and then again mounted in glycerine. The intensity of birefringence was again determined at the same sites.

It has been found that in longitudinal sections the negative birefringence of myelin was decreased by about 40 per cent in the extracted sections. In transverse sections the positive birefringence was decreased by about 60 per cent of the value in untreated sections. As it is known[6] that cholesterol is positively birefringent it is obvious that its molecules are radially arranged and their presence contributes to the negative birefringence in longitudinal sections and to positive birefringence in transverse sections.

The evidence for a radial arrangement of the cholesterol moieties in myelin corroborates the scheme which has been suggested by Finean's X-ray diffraction studies.

PATHOLOGY

Ependymomas produced after Intracerebral Inoculation of *SV40* into New-born Hamsters

Eddy *et al.*[1] have reported that extracts of rhesus monkey kidney cell cultures produce subcutaneous sarcomas when inoculated into new-born hamsters. Sweet and Hilleman[2] have shown that a simian virus (*SV*40) is present in most rhesus monkey kidney cell cultures although it causes no cytopathogenic effect in them. Cytopathogenic effect is produced, however, in cell cultures of kidneys from African green monkeys. Later, Eddy *et al.*[3] found that similar subcutaneous

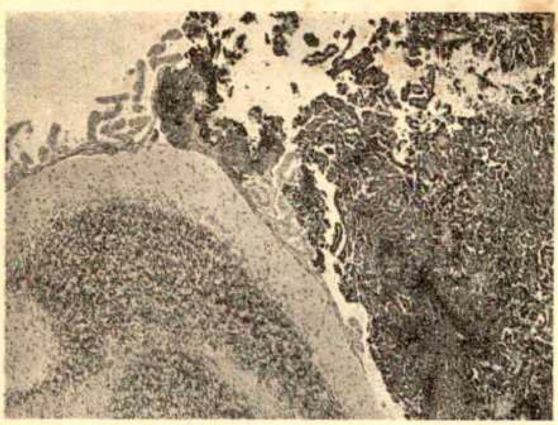

Fig. 1. Ependymoma of lateral ventricle of hamster inoculated with *SV*40. Transition from normal ependyma to tumour is seen. Hæmatoxylin and eosin (× *c*. 39)

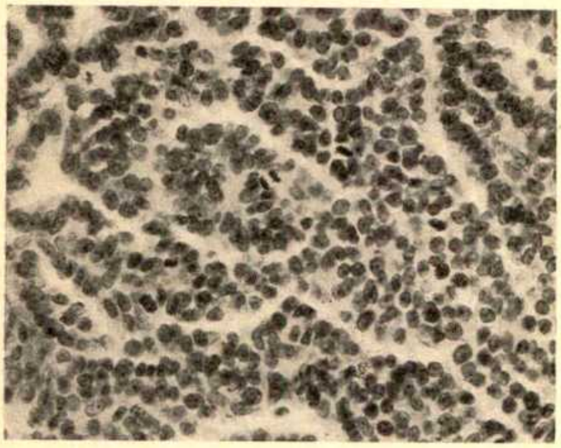

Fig. 2. Numerous mitotic figures in a cellular area of the ependymoma. Hæmatoxylin and eosin (× *c*. 530)

sarcomas in hamsters can be induced after inoculation of preparations containing *SV*40.

Since it has been previously shown that new-born hamsters are markedly susceptible to the induction of tumours after intracerebral inoculation of polyoma virus[4], studies were undertaken to determine the effect of intracerebral inoculation of large doses of *SV*40 into new-born hamsters.

Strain 777 of *SV*40 used in this work has been isolated in this laboratory. The virus pool was prepared in cell cultures of African green monkey kidneys in serum-free medium 199 (ref. 5). This virus preparation contained $10^{8\cdot7}$ $TCID_{50}$/ml.

Pregnant Syrian hamsters (*Cricetus auratus*) were obtained from the animal production unit of the National Institutes of Health and the litters were used for intracerebral inoculation. One litter of 11 animals was inoculated when less than 24 hr. old with 0·02 ml. of virus fluid. One litter of 9 animals of the same age was inoculated with 0·02 ml. of medium 199. The inocula were injected into the mid-portion of the right cerebral hemisphere using tuberculin syringes and No. 27 gauge ¼-in. needles. The animals were observed daily for evidence of neurological dysfunction. At the time of death, complete autopsies were performed and the tissues were fixed in formol–mercuric bichloride (sublimate). Sections for microscopic study were stained with hæmatoxylin and eosin and phosphotungstic acid hæmatoxylin.

Two of the 11 baby hamsters inoculated with virus fluid were eaten by the mother and 9 remained by the seventh day. Daily observation revealed no abnormalities until 100 days after inoculation. At that time 2 of the 9 appeared weak and lethargic. This weakness rapidly progressed to complete paralysis of all limbs, and these 2 animals were killed on the 100th and 101st days respectively. A third animal developed paralysis on the 111th day and was killed. Three more animals were killed on the 124th day even though there were no signs of weakness. At the time of this report (156 days) the remaining three animals appear well clinically.

Of the 9 control animals, 2 were eaten by the mother. Seven remain well clinically at 156 days.

At autopsy, all three paralysed hamsters had grossly discernible tumours of the brains. These were white and appeared to be present in the anterior horns of the lateral ventricles. The tumour of the third animal killed on the 111th day was very large and had caused marked dilatation of the lateral ventricles. One of the 3 normal appearing animals also had a tumour.

All 4 tumours had the same histological appearance. They filled the lateral ventricles of the cerebrum. They consisted of cords and rosettes of cuboidal cells with dark-staining nuclei and scant cytoplasm. Transition from the normal ependymal lining of the ventricle to tumour was seen (Fig. 1). In many areas, the tumour cells were arranged in a papillary fashion. In others, the cells were compact and arranged in sheets. Mitotic figures were numerous (Fig. 2) and the tumours were quite vascular.

These tumours have the characteristics of ependymomas, tumours arising from the ventricular lining cells[6].

The stroma of the tumour of the third animal had, in addition to normal connective tissue, areas of sarcomatous tissue and numerous multinucleated giant cells. These areas are similar histologically to the subcutaneous sarcomas described by Eddy *et al.* after inoculation of extracts of rhesus monkey kidney cell cultures[1].

Although the tumours produced by intracerebral inoculation of polyoma virus in hamsters are sarcomas and resemble the subcutaneous tumours produced by this agent, the tumours produced after intracerebral inoculation of *SV*40 are ependymomas. Such tumours are true gliomas and thus are of ectodermal origin. Ependymomas have been produced after implantation of carcinogens into the brains of experimental mice[7]. This, however, represents the first report of the production of a true glioma after virus inoculation.

IMMUNOLOGY

Immunization of the *A/Jax* Mouse with Irradiated Cells of its Indigenous Tumour, Sarcoma I

One of the transplantable tumours widely used in investigations of tumour immunology is Sarcoma I (SaI), a tumour that originated in 1947 in a mouse of the Strong *A* strain that had been treated with dibenzanthracene[1] We, as well as others, have maintained the tumour by transplantation in mice of the *A/Jax* strain, a sub-line of the Strong *A* strain, and utilize animals of this strain as the susceptible host in various experiments Since any immunological response, even though it may be insufficient to cause rejection of the tumour, may influence the results of experiments with this tumour–host system, it appeared desirable to determine whether an immunological response to SaI occurs in the *A/Jax* mouse From work of others it appeared that the possibility of an antigenic disparity between the tumour and the *A/Jax* mouse is favoured by the likelihood of genetic change in the mouse or the tumour during the prolonged period of transplantation and by the fact that the tumour was induced by dibenzanthracene[2,3]

Experiments were designed to demonstrate immunity to SaI in adult *A/Jax* animals by treatment with irradiated SaI ascites tumour (SaI-AT) prior to challenge with a lethal dose of SaI cells (The *A/Jax* mice used were obtained in 1958 from the Roscoe B Jackson Memorial Laboratory, Bar Harbor, Maine They were maintained in our laboratory by colony inbreeding for seven generations before use)

The irradiation of SaI-AT cells was accomplished by X-ray treatment of adult *A/Jax* mice bearing an ascites tumour transplanted seven days earlier Irradiation was delivered by a cobalt-60 source at a rate of 200 r /min and a distance of 35 cm The field size was 10 cm × 10 cm and the total exposure doses ranged from 18,000 r to 36,000 r (Dr R. G Parker assisted in the radiology)

Table 1 Immunity to Sarcoma I induced in *A/Jax* Mice with Irradiated Tumour Cells

Route of administration of irradiated cells	Days after challenge with live SaI-AT cells 10	20	30	40	50	100	MST*
Intraperitoneal	0/12†	1/12	6/12	7/12	8/12	8/12	27 6
Intradermal	0/12	2/12	6/12	9/12	10/12	10/12	28 7
Untreated controls	0/14	14/14					17 1

* Mean survival time

† The numerator designates the total number of animals dead of tumour at the interval shown and the denominator the total number of animals tested

Immediately after irradiation, the ascites fluid was removed with a 26-gauge needle and the tumour cells were counted Ten million irradiated cells were injected into each of 12 female and 12 male adult *A/Jax* mice The cells were deposited either intraperitoneally or intradermally in multiple sites of the skin and foot pads

Fifty days after the administration of the immunizing dose of irradiated tumour cells all animals were given an intraperitoneal challenge dose of 1,000 viable ascites tumour cells This number of tumour cells was equal to at least 100 lethal doses

The data presented in Table 1 show that whereas all the control mice died of tumour before the 21st day many of the immunized mice survived for longer periods Six of the 24 animals in the latter group were alive and healthy on the 100th day following challenge and at death showed no indication of tumour The mortality-rates and survival-times of the immunized mice were not significantly different in female and male animals or in animals immunized by the two routes

The results show that irradiated SaI-AT cells are immunogenic for the *A/Jax* mouse and indicate that antigenic differences exist between the *A/Jax* mouse and its indigenous tumour Sarcoma I

Staphylococcal Infection and Blood Groups

Many workers have shown similarities between blood group substances and a variety of bacterial and non-bacterial antigens Illchmann-Christ and Nagel[1] found that anti-A antibody was removed from B and O sera by *Staphylococci* and reasoned that *Staphylococci* possessed an A-like receptor This suggests that persons of blood group A may have an increased susceptibility to staphylococcal infection due to an inability to elaborate an antibody which may cross-react with their own red blood cells

Anderson, Coulter and Keynes[2] reported an extensive epidemiological investigation into staphylococcal infection and nasal carriage among mothers, babies and staff in a maternity hospital No attempt was made at the time to correlate blood group with other inquiries, but this has now been done retrospectively

All blood groups of mothers were recorded Each mother was nose swabbed five times between the 36th ante-natal week and the 6th post-natal week At the visit on the 36th week, each mother was questioned about previous staphylococcal infection and at the post-natal visit inquiries were made concerning infection following discharge from the hospital The results are presented in Table 1

Table 1

	Blood group of mother A	B	AB	O
Nasal carrier	127	22	7	135
Not nasal carrier	207	62	19	193
Positive history of staphylococcal infection	77	22	7	98
Negative history of staphylococcal infection	178	42	13	149
Staphylococcal infection in baby	29	15	0	37
No staphylococcal infection in baby	170	36	13	158

This table may be summarized nasal carriage, O > A* > AB > B, history of staphylococcal infection, O > AB > B > A* < O

* Indicates significance (χ^2 test $P < 0\ 05$)

Group O persons are seen to be at a slight disadvantage both as regards nasal carriage and overt infection It is doubtful whether these slight differences are of any clinical significance

RADIOBIOLOGY

Immediate Effects of X-Irradiation on the Heart of the Frog

Recent work has shown that ionizing radiations increase the excitability of peripheral receptors[1], nerves[2–4], nervous centres[4], muscles[4], and embryo heart of the chick[5]

In the work reported here, the influence of whole-body irradiations on the heart of a frog was studied according to the following technique The frogs (*Rana temporaria*) were pithed through brain and cord, after opening the thorax and pericardium, the ventricle basis was pinched with a small clip and kept still, while the apex, pinched in the same way, was connected to a strain gauge and electric recorder (Philips 'Cardiopan') This system allows a continuous record, before, during and after irradiation, of ventricular isometric contractions In some cases, the electrocardiogram was taken simultaneously

Irradiations were carried out with a Siemens 'Stabilipan' X-ray tube, for a period of 5 min (195 kV, 20 m amp, filter 0 2 mm copper, focal distance 17 cm, dose-rate 950 r /min)

Fig 1 shows the effect of X-rays on heart beat The strong bradycardia observed after 1–5 min of irradiation is reversible within 1 min after irradiation and often followed by a transient acceleration This effect can be repeated several times on the same animal by successive irradiations In some instances, the cardiac frequency was reduced to half, the electrocardiogram, however, did not reveal any auricular-ventricular block, while in three experiments, a sino-auricular block was noticed by direct observation during the first minute after irradiation

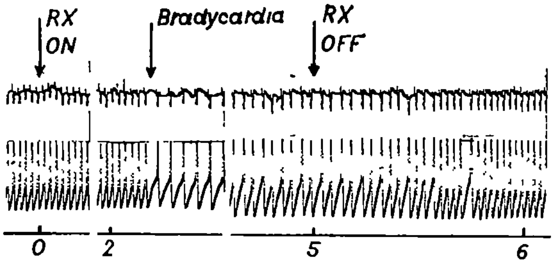

Fig 1 Reversible bradycardia by X-irradiation Upper trace electrocardiogram which shows *P* and *R* waves, lower trace isometric contractions, time is indicated in minutes

In other cases, no modification of cardiac rhythm was obtained even after a much longer period of irradiation This lack of response is not related to the sex of frogs, but seem dependent on seasonal variations, in October, 9 of the 18 frogs tested did not respond, while during the colder months, November–January, bradycardia appeared in two cases only out of 13, though the animals were acclimatized at laboratory temperature for a week When the frequency was unchanged during irradiation, a reversible decrease of contractile strength (10–20 per cent) occurred in the non-hibernating frogs (October)

These negative chronotropic or inotropic effects suggest a vagal participation in the phenomenon Consequently, the action of atropine and eserine solutions, spread upon the heart area 5 min before irradiation, was investigated in the animals, showing a good chronotropic effect

As shown in Fig 2, atropine sulphate solution (0 1 per cent) almost completely inhibits bradycardia induced by X-rays, after washing the preparation it is still possible to induce by a new irradiation the characteristic heart rate decrease Accordingly, physostigmine salicylate solution (0 1 per cent) increases the bradycardia as compared to a preceding irradiation without drug, but washing the preparation does not restitute the primitive state These two drugs seem to act in the same way on the X-rays induced decrease of contractile strength

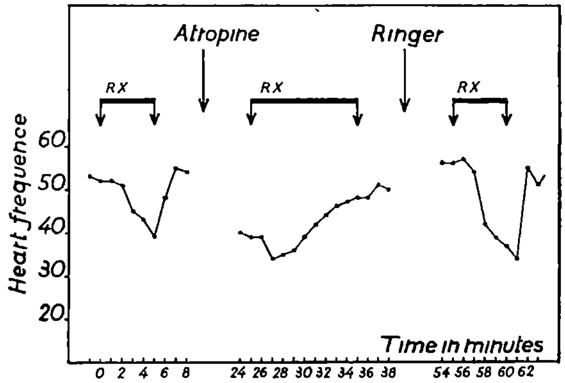

Fig 2 Successive irradiations of the same frog, effect of atropine sulphate, 0 1 per cent

High dose-rate X-irradiations induce in the spinal frog's heart a negative chronotropic or inotropic action These effects are inhibited by atropine and potentiated by eserine Hibernating frogs, as a rule, do not react The present observation suggests the occurrence of a vagal excitation or acetylcholine liberation under the influence of irradiation

Sensitivity of Interphase Cells to Chromosome Breakage by X-rays

Several previous studies have dealt with the sensitivity of interphase cells to chromosome breakage by X-rays In the root tips of beans (*Vicia faba*) Revell[1] observed that the sensitivity reaches its maximum about 8 hr prior to mitosis According to Howard and Pelc[2] this time lies in the post-DNA-synthetic period (G_2) The results obtained by Sparrow *et al* [3] in *Trillium* microspores are also similar to those of Revell In a recent investigation of the survival of HeLa cells Terasima and Tolmach[4] have found that the irradiation of interphase cells, which are presumably in the process of synthesis of DNA (S), reduces their capacity to form colonies more markedly than when they are irradiated at other stages of interphase In the present work, using tritiated-thymidine to identify directly DNA-synthesizing cells, it is shown that these cells, which are in the S-phase at the time of irradiation, are more sensitive to chromosome breakage than cells at other stages of interphase (G_1 and G_2)

Table 1. MEAN FREQUENCIES/ROOT OF LABELLED AND UNLABELLED ANA- AND TELO-PHASES, CONTAINING CHROMOSOME ABNORMALITIES (ONION)

Time (hr.) after X-rays	Labelled ana- and telo-phases		Unlabelled ana- and telo-phases	
	No. scored	Per cent abnormal	No. scored	Per cent abnormal
3½	0	0	234	17.4 ± 3.8
6½	25	40.0	83	26.2 ± 10.3
9	23	52.2	65	32.6 ± 21.3
20½	114	64.1 ± 3.8	88	33.2 ± 3.4
24	40	44.5 ± 5.6	83	19.9 ± 5.2
32½	42	30.3 ± 10.3	122	13.8 ± 7.1
Total	244	46.2 ± 2.6	675	23.8 ± 4.2

No. of roots: 3 at 3½ to 9 hr.; 2 at other times. Only one root at 6½ and 9 hr. contained labelled ana- and telo-phases. Mitotic rate reached control-level at 20½ hr.

Onion and bean root meristems were exposed to tritiated thymidine (1 μc./ml., spec. act. 1.9 c./mM) for 16 min., during the last 4 min. of which they were irradiated with 200 r. (for irradiation procedures see our earlier work[5]). After irradiation, roots were allowed to grow in tap water containing unlabelled thymidine (0.05–0.1 mgm./ml.). Controls with unirradiated and irradiated roots were run in order to determine the effect of tritiated thymidine on chromosome breakage. Samples were fixed in acetic alcohol at various times after irradiation. Stripping film autoradiographs of Feulgen-stained squash preparations were made and the frequencies of labelled interphase cells and labelled and unlabelled ana- and telophases containing chromosome aberrations (fragments and bridges) were determined. In control samples, not covered with stripping film, the overall frequencies of abnormal cells (both mitotic and in interphase, possessing chromosome fragments in the form of micronuclei) were observed.

The frequency of radioactive nuclei (37.5 per cent) observed in onion roots which were exposed to tritiated thymidine for 16 min. was about the same as that (37.6 per cent) found in roots grown for 3½ hr. longer in unlabelled thymidine. Furthermore, in the latter samples no increase in silver grain density over labelled nuclei is apparent. Similar results were also obtained in the bean root tip cells. These findings show that the pools of tritiated thymidine in both onion and bean roots are diluted very rapidly after the roots are transferred to unlabelled thymidine (cf. Wimber[6]). Therefore almost all labelled cells that are detected after irradiation represent those which underwent synthesis of DNA at the time of exposure to X-rays.

It can be seen in Tables 1 and 2 that during the entire experimental periods in both onion and bean root the frequencies of labelled ana- and telo-phases containing chromosomal aberrations are much higher than the frequencies of unlabelled aberrant mitoses. The results in Tables 1 and 2 are presented in slightly different ways, because a high variability of aberrations among individual roots in each sample was observed in the onion, but not in the bean; in either case, however, the differences between frequencies of aberrant mitoses in labelled and unlabelled cells are highly significant. The increase in the frequency of labelled aberrant mitoses is not brought about by a synergistic effect of tritiated thymidine and X-rays, since the data in Table 3 clearly show that there is no difference between the per cent abnormal cells obtained from onion roots irradiated in the presence and absence of tritiated thymidine. Moreover, an exposure of unirradiated roots to tritiated thymidine for only 16 min. does not produce any abnormal cell (Table 3, last column). These results, therefore, demonstrate that, among interphase cells in both onion and bean, the sensitivity to chromosome breakage by X-rays is at its maximum in cells which undergo DNA synthesis at the time of irradiation. (This observation is in agreement with that of S. Mitra (*Genetics*, 43, 771; 1958) on X-rayed meiotic cells of lily.) Such chromosomal damage may account for the marked reduction in colony-forming capacity of HeLa cells irradiated at the time of synthesis of DNA[4].

The present data do not permit us to determine clearly any difference in the sensitivity between post-synthetic (G_2) and presynthetic (G_1) cells. The total duration of the mitotic cycle in these materials is fairly well known[2,7]. It normally requires more than 12 hr. for cells in the G_1 stage to reach the next mitosis; consequently, the unlabelled mitoses which appear in the earliest samples (up to 9 and 12 hr.) of the present work were furnished by cells which had been in G_2 during irradiation. Since one of the immediate effects of radiation is to block cells in the G_2 stage[8,9] without greatly affecting the process of synthesis of DNA[5], the unlabelled mitoses in later samples consist of a mixture of cells that had been in G_2 and G_1 at the time of exposure to X-rays.

Although the reason for a high sensitivity of cells in the S-period, compared to those in G_2 to X-irradiation, is not apparent on the basis of "target theory"[10], it is possible that the susceptibility of chromosomes to breakage by X-rays increases when the DNA double helix is opened up at the time of replication. It is also possible that chromosome damage occurring during

Table 2. FREQUENCIES OF LABELLED AND UNLABELLED ANA- AND TELO-PHASES, CONTAINING CHROMOSOME ABNORMALITIES (BEAN)

Time (hr.) after X-rays	Labelled ana- and telo-phases (A)			Unlabelled ana- and telo-phases (B)			Test of significance between A and B

BIOLOGY

Antagonism by Deoxyribonucleic Acid Extracts of the Growth Inhibitory Effects of 8-Azaguanine on Mammalian Cells in Culture

IN a series of *in vitro* experiments involving attempts to transfer resistance to 8-azaguanine (AzG), a non-specific effect of cell preparations rich in deoxyribonucleic acid (DNA) has been observed

The continuous cell line used, *P*–388[1,2], was maintained in Eagle's basal medium supplemented with L-serine (0 2 m*M*), sodium pyruvate (1 m*M*) and calf serum (5 per cent) This cell line shows a consistent behaviour with respect to inhibition of growth by 8-azaguanine and the other inhibitors used in this investigation[3]

In these experiments a suspension of cells was inoculated into glass Petri dishes (6 cm diam) containing 8-azaguanine and DNA, then incubated at 37° C in an atmosphere of 5 per cent carbon dioxide–95 per cent air After 7 days incubation, the contents of the dishes were stained with crystal violet and the number of colonies per dish was counted using a dissecting microscope[2]

Extracts rich in DNA were obtained by the method of Kay, Simmons and Dounce[4] DNA precipitates were never dried but taken into solution in either 0 0014 *M* or 0 14 *M* sodium chloride solution

As shown in Table 1, the presence of the DNA extract leads to the appearance of large numbers of colonies at concentrations of 8-azaguanine which completely inhibit growth in the absence of the DNA With a constant concentration of 8-azaguanine, decreasing the amount of the DNA preparations per dish results in a graded decrease in the number of colonies per dish (Table 2)

Table 1 EFFECT OF DNA EXTRACT ON 8-AZAGUANINE INHIBITION OF GROWTH OF *P*388/*P*

	2×10^{-6} *M*	0	82

* Each value is the average from 3 dishes
† DNA extract from *P*388/*P* , 0 1 ml per dish = 100 μgm DNA
‡ Plating efficiency , 295 cells inoculated per dish

These results can possibly be explained in the following ways (1*a*) The DNA-rich preparations contain as impurities substances capable of binding the 8-azaguanine, etc , thus lowering the effective concentration of the drug, (*b*) in the presence of the cells, under these experimental conditions, substances can be released from the DNA extracts which effectively bind the 8-azaguanine, etc , and/or (2) the DNA extracts contain, or release on incubation, a compound or compounds which inhibit the uptake of the 8-azaguanine, etc , into the cells

There is evidence (Table 1) that the presence of the DNA extract does not merely increase the plating efficiency of the cells The regularly graded effect found with increasing concentrations of 8-azaguanine (Table 1) and also the non-specificity with respect to the source of the DNA extract strongly suggest that the colonies found are not truly resistant cells

The nature of this effect is being investigated further since, if it is a property of some substance released from highly purified native DNA under the experimental conditions used, it will be difficult to assess experiments of this nature with compounds such as 8-azaguanine and 6-mercaptopurine

However, if the activity is due to some contaminant carried through, or arising during the procedure of extracting, DNA then it may be possible to remove it prior to experimental use of the DNA extract

'Messenger RNA' in a Fission Yeast

It is now widely believed that one fraction of the ribonucleic acid (RNA) of a cell, the 'messenger RNA', is responsible for the transmission of genetic information from the deoxyribonucleic acid (DNA) of the nucleus to the cytoplasm[1] This messenger RNA has been identified with that fraction of the total RNA which shows some or all of the following properties a high rate of turn-over, a physical difference from the ribosomal RNA, a base composition similar to the DNA, and a capacity to interact specifically with the DNA Evidence for the existence of this RNA has come from phage-infected bacteria[2,3], normally growing bacteria[3], and mammalian nuclei[4,5] It has also come from bacteria[6] and budding yeast[7] in a 'step-down , where growing cells are transferred from a rich medium to a poor one For a period after the step-down it seems that messenger RNA is the main kind of RNA made by the cells We have investigated this situation in the fission yeast *Schizosaccharomyces pombe* with the object both of identifying messenger RNA and also of following by autoradiography its location in the cell and its relation to the cell-cycle

When yeast cells growing exponentially in malt extract broth at 32° C were transferred to a minimal medium containing 4 75 per cent ethanol at the same temperature, the optical density at 595 mμ remained constant for 20–30 min At the end of this plateau following the step-down, the optical density rose exponentially for several generations with a mean generation time of 6 hr The mean generation time in the normal minimal medium was 3 hr and in the malt extract broth was 2½ hr Total RNA remained constant for a longer period (1 hr) after the step-down These results are similar to those found with bacteria[8,9] except that the mean cell size of the yeasts did not change appreciably after the step-down

Continuous and pulse labelling with $^{32}PO_4$ and ^{14}C-adenine showed that RNA continues to be synthesized after the step-down The initial rate of incorporation was 3–7 per cent of that in control cells growing in normal minimal medium The kinetics of labelling with phosphorus-32 followed by an excess of phosphorus-31 as a 'chase' showed that a substantial proportion of this RNA was turning over The results from two experiments are shown in Fig 1 The decline in counts after the chase indicates instability of the labelled RNA In the control, which is not illustrated, the phosphorus-32 in RNA did not fall after the chase but rose at the expense of phosphorus-32 in the acid-soluble pool Similar experiments with ^{14}C-adenine gave somewhat different results The control behaved in the same way as that with phosphorus-32 the acid-insoluble label (RNA) rose after the chase while the acid-soluble declined After a step-down and chase, however, the acid-insoluble label only rose slightly and the acid-soluble label stayed constant. The difference between the results with phosphate and adenine is presumably because the former can exchange with the medium while the latter cannot The results with adenine after a step-down are compatible with an unstable RNA exchanging with an internal pool of nucleotides This pool would only be slowly accessible to adenine entering the cell and it would not exchange with adenine in the outside medium

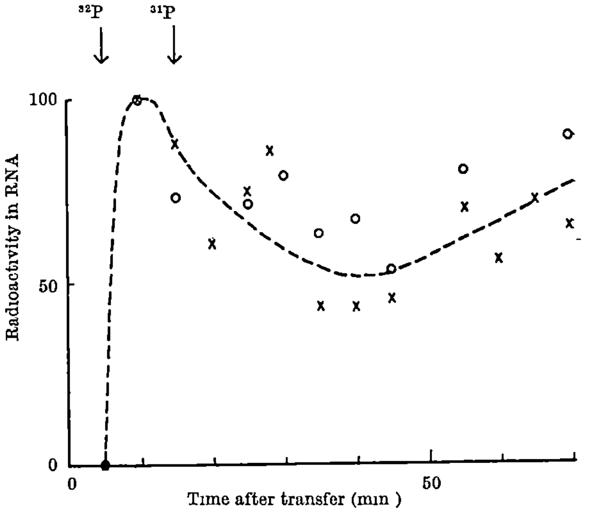

Fig 1 Phosphorus-32 label in RNA after step-down Cells transferred at zero time from malt extract broth to minimal medium with 4 75 per cent ethanol At 5 min , cells were labelled with carrier free $^{32}PO_4$ At 15 min., excess $^{31}PO_4$ was added (1,000 × conc in medium) Acid washed cells were counted at intervals on membrane filters before and after digestion with RNAase Difference in counts was taken as measure of radioactivity in RNA Two experiments with different labelling levels (0 33 and 1 0 μc /ml) normalized to 100 after 5 min labelling ○, 0 33 μc /ml , ×, 1 0 μc /ml

RNA nucleotide ratios are shown in Table 1 Those for the bulk (largely ribosomal) RNA are the means of the ultra-violet absorption data from all the experiments They do not differ significantly from those for *Saccharomyces cerevisiae*[7] Control cells growing in minimal medium were labelled for a generation time (3 hr) with phosphorus-32 The radioactive base ratios were very similar to those from the bulk, except that the CMP was somewhat lower With control cells labelled for 10 min , the ratios were disturbed, both UMP and GMP being depressed relative to AMP This tendency was even more marked in a step-down culture (10-min label started 5 min after transfer) Here the GMP is severely depressed and is nearly equal to the CMP. Only the low UMP stops these ratios being similar to those for the DNA of *S cerevisiae*[7] Base ratios for the DNA of *S pombe* have not yet been found, but this work is going forward

It is clear that the RNA made immediately after a step-down has a very different composition from the

Table 1 RNA Nucleotide Ratios

	Bulk (ribosomal) ultra-violet	Control Phosphorus-32 for 3 hr	Control Phosphorus-32 for 10 min	Step-down Phosphorus-32 for 10 min
AMP	10	10	10	10
UMP	9 9	9 5	8 8	7 0
GMP	10 2	9 1	7 6	6 5
CMP	7 1	5 6	6 5	6 1

RNA extracted by hot 10 per cent sodium chloride, and deproteinized with chloroform-octanol Nucleotides separated by electrophoresis on cellulose acetate strips after alkaline hydrolysis Radioactivity measured by scintillation counting Acid eluates measured in ultra-violet

ribosomal RNA and that the deviation is in the direction of DNA (with U replacing T) RNA labelled with a brief pulse of phosphorus-32 during exponential growth also deviates in the same direction, though not so markedly These results are consistent with the view that messenger RNA is a significant fraction of the RNA synthesized during a brief interval[3,7], though they suggest that this fraction is larger after a step-down than in normal growth

^{14}C-leucine was incorporated into acid-insoluble material at a relatively high rate for the first $\frac{1}{2}$ hr after a step-down As judged by pulse labels, this rate was about 30 per cent of that in a control growing in normal minimal medium This, coupled with the constant optical density, suggests that there is a considerable amount of protein turn-over after a step-down

Autoradiographs were made of cells labelled for 10 min with ^{3}H-adenine at various periods after a step-down, and were analysed by a method described elsewhere[10] Preliminary results show that the label is present both in nucleus and cytoplasm, though the nuclear concentration is higher They also show that cells of different length and therefore at different stages of the cell-cycle incorporate approximately equal quantities of the label This latter result differs from that with normal growing cells where the rate of incorporation rises steadily throughout the cell-cycle[11]

In summary, this work shows that fission yeasts, after a step-down in medium, produce for a time RNA which is unstable and which has a base composition unlike ribosomal RNA and approaching DNA We would therefore identify it tentatively as messenger RNA It also seems that its pattern of synthesis during the cell-cycle differs from that in normal growth

Pathways of Adenosine Triphosphate Production by Calf Lens Homogenates

In previous work we investigated the phosphorylations occurring in homogenates of various zones of the crystalline lens of a calf incubated with glucose-6-phosphate[1] The transformation of adenosine diphosphate (ADP) into adenosine triphosphate (ATP) was measured by isolation of the nucleotides by column chromatography 'Dowex 1 × 8' 200–400 mesh (formate form) The application of such a method is rendered possible by the very feeble ATPase activity of the lens We saw that the intensity of phosphorylation diminished on passing from the anterior zone, constituted by the epithelium and young fibres, towards the older fibres of the cortical and central zone The aim of the present work was to determine the extent of phosphorylation due to anaerobic glycolysis, the Krebs cycle and possibly to the pentose cycle by a transdehydrogenation reaction reduced coenzyme 2 + coenzyme 1 → reduced coenzyme 1 + coenzyme 2

Our experiments were carried out on homogenates of the cortex of calf lenses in a solution of 0 12 M potassium chloride + 0 02 M sodium bicarbonate, 1 gm wet tissue being used per 2 ml solution The conditions of incubation and the results are summarized in Table 1

Table 1

Substrates	Quantity of ATP formed (μmoles)
Homogenate + oxygen	0 2
Homogenate + glucose + oxygen	2 6
Homogenate + galactose + oxygen	0 2
Homogenate + ribose-5-phosphate + oxygen	1 6
Homogenate + fructose-1,6-phosphate + oxygen	9 9
Homogenate + 3-phosphoglycerate + oxygen	3 4
Homogenate + α-cetoglutarate + oxygen	0 2
Homogenate + glucose-6-phosphate + oxygen	5 3
Homogenate + glucose-6-phosphate + nitrogen	5 2
Homogenate + glucose-6-phosphate + CH_2ICOOH	0 5
Homogenate + glucose-6-phosphate + TPN	0 6
Homogenate + glucose-6-phosphate + TPN + DPN	0 6

Incubation medium Homogenate, 3 ml All substrates at a concentration of 0 01 mM, ADP, 0 012 mM, monoiodoacetate, 0 1 mM, coenzyme 2 (TPN), 3 μM, coenzyme 1 (DPN), 2 7 μM Final volume 8 ml Incubation, 15 min , at 37°, stopped by rapid cooling plus addition of 2 ml of 1 2 N perchloric acid

The results show that, in our experimental conditions, the amount of phosphorylation involving galactose is almost nil, that involving glucose is high Glucose-6-phosphate was more efficiently used, but most phosphorylation was obtained with fructose-1,6-diphosphate We observed that the production of ATP was the same whether or not oxygen was present, a fact indicating that the Krebs cycle can contribute only to a very small extent to the production of ATP in the lens This does not mean that the Krebs cycle pathway is not utilized in the lens *in vivo*, one of us has in fact noted a true respiration of the mitochondria of the lens cortex even though these are scarce[2]

The addition of monoiodoacetate to the incubation medium blocks almost completely the phosphorylation of ADP The production of a small quantity of ATP was, in fact, observed, but at the same time the amount of AMP increased so that the ATP formed could be attributed to the myokinase activity which we have shown to exist in the lens[3] The observed excess of AMP in relation to ATP indicates that a part of the ATP formed by the myokinase activity was utilized in the transphosphorylation reactions which we have found in similar homogenates It is noteworthy that this augmentation of AMP does not occur in conditions in which phosphorylation is active and that, in this latter case, the myokinase activity does not appear

The possibility of production of ATP by the pentose cycle and by the route involving transdehydrogenation of reduced coenzyme 2 was investigated by the addition of coenzyme 2 to the incubation medium containing glucose-6-phosphate and monoiodoacetate, the latter to block glycolysis We observed the formation of a considerable quantity of adenosine diphosphate–ribose–phosphate, the product of acid decomposition of reduced coenzyme 2 This corresponds to an almost complete utilization of coenzyme 2 In these conditions, only a supplementary production of ATP which represents about 1 3 per 100 of the ATP formed by simple anaerobic glycolysis was observed This fact indicates that, if the pentose pathway does produce ATP in the lens, it can only give very small quantities It was also observed that the addition of coenzyme 1 which would favour transdehydrogenation was quite ineffective, no reduced coenzyme 1 and no more ATP being formed This observation shows that the possibility of energy production involving transdehydrogenation cannot be demonstrated in the lens *in vitro* Therefore, in our *in vitro* conditions at least, anaerobic glycolysis seems to be the sole source of ATP in the lens The Krebs cycle or the pentose cycle seems to provide ATP in quantities negligible by comparison with those provided by anaerobic glycolysis The preferential utilization of glucose-6-phosphate and particularly of fructose-1,6-diphosphate indicates either the fragility of enzymes forming hexose diphosphate or that these enzymes represent limiting factors

Summarizing, the most efficient production of ATP from ADP by lens homogenates was obtained through fructose-1,6-diphosphate The addition of coenzyme 2 with or without coenzyme 1 caused an almost quantitative production of reduced coenzyme 2 Monoiodoacetate blocked the phosphorylation of ADP almost entirely, whatever substrate was used The same quantity of ATP was produced with or without oxygen The pentose cycle seems capable of producing only very small quantities of ATP

Dividing Cells as the Locus for Vernalization

IN an earlier communication[1] I described the "leaf vernalization" of leaf cuttings of *Lunaria biennis* After cold treatment, such cuttings from leaves of adult plants regenerate and yield flowering plants, while without a cold treatment no flowering occurs It was left undecided exactly where in the leaf cutting the vernalization takes place—in the leaf as a whole or in meristematic cells only Evidence has been obtained now that the locus of vernalization consists of cells which are in the process of mitosis

First of all, this concept explains some of the former results which were not clear originally Vernalization of leaf cuttings requires much longer cold treatment than is needed for intact plants The explanation which offers itself now is that for vernalization mitosis should start and that this takes considerable time at the low temperature of 5° C , which time must be subtracted from the total period of cold treatment to find the actual time of vernalization On the other hand, when leaf cuttings were allowed to start rooting by keeping them at ordinary greenhouse temperature for 2 weeks before the cold treatment, a much shorter period of cold treatment was sufficient for vernalization In this case mitosis had set in when the plants were exposed to low temperature

Secondly, the results of an experiment with root cuttings completely confirm those with leaf cuttings *Lunaria biennis* forms a number of thick 'contractile' roots, and these regenerate as cuttings better and even much better than leaf blades with petioles Groups of 25 root cuttings were exposed to 5° C for 0, 8, 12, 16 or 20 weeks respectively and were afterwards grown at a greenhouse temperature of about 20° C Flowering of the regenerated root cuttings occurred for 0, 8, 80, 100 and 100 per cent respectively When the root cuttings were kept at greenhouse temperature for 2 weeks before cold treatment, the percentages of flowering were 0, 80, 100, 100 and 100 per cent respectively The mean numbers of days from the end of the cold treatments to the appearance of the first visible flower bud were inversely proportional to the duration of the cold treatment In itself these results would point to the existence of 'root vernalization', but in comparison with the results of vernalization of leaf cuttings it seems more appropriate to speak of 'vernalization of dividing cells'

Thirdly, there are at least two possibilities for a direct test of this hypothesis As a matter of fact, they have led to a reconsideration of the former results and to an interpretation of the results with root cuttings as discussed here Hagemann[2] found that leaf cuttings from naturally overwintered plants regenerated into flowering plants In repeating this experiment, originally leaf cuttings were made from plants immediately after a prolonged artificial cold treatment, and no flowering occurred This means that intact leaves on their plants cannot be vernalized, while isolated leaves + petioles can be vernalized, as already stated The difference lies in the fact that in the latter case mitosis occurs during cold treatment When, in a second attempt Hagemann's experiment was repeated under identical conditions, the leaf cuttings indeed regenerated into flowering plants In this case the cuttings were made of leaves which were still growing during the exposure to cold, while in the first case the leaves were already full-grown when cold treatment was begun

The second test consists of removing the lower part of the petioles (where the mitoses occur) of leaf cuttings immediately after cold treatment, to make them re-regenerate and to see whether flower formation will take place In anticipation of an extensive experiment a preliminary test was made with rather poor plants during the bad growing conditions of the winter After cold treatment for 20 weeks, 16 cuttings re-regenerated after removing the lower portion of their petioles over a length of 0 5 cm None of them flowered, while 5 out of 24 cuttings, which were left intact, have flowered The number of flowering cuttings in the last group is rather small and this makes the total results not yet fully conclusive However, they do not disprove my hypothesis

Taking into consideration all the arguments discussed here, the conclusion may be drawn that they present evidence that vernalization occurs only in cells which are in the process of mitosis Of course the well-known fact that seed vernalization occurs only in germinating seeds supports this view

Effect of Temperature on Hatching in the Cereal Root Eelworm

Unlike most other species of *Heterodera*, the larvæ of the cereal root eelworm (*Heterodera avenae* Wollenweber, 1924) do not hatch in response to diffusates of the host plant root[1] The mechanism controlling hatching in this species has never been demonstrated, although it has been known for many years that in the field larvæ invade the roots of the host plant in the greatest numbers in spring and early summer[2] Experiments carried out at the Welsh Plant Breeding Station during the summer and winter of 1961/62 indicate that, in the laboratory, hatching of the cereal root eelworm occurs in response to a rise in temperature after a period of low temperature

In the first experiment cysts obtained from soil in July were stored in tap-water at 5° C and at room temperature (12°–22° C) for 90 days At the end of that period both lots of cysts were set up to hatch in tap-water at 21° C and over 14 days hatching was strongest among those which had been stored at 5° C (Table 1)

Table 1. Mean Daily Hatch per 100 Cysts at 21° C

After 90 days at room temperature	After 90 days at 5° C.
10 9	72 3

In a second experiment, cysts obtained from soil in October were set up to hatch in tap-water at 5° C and at 21° C Over 62 days there was no difference between the hatching under the two treatments, for the cysts at 5° C , the mean hatch was 9 4 per 100 cysts per day, while for the cysts at 21° C the mean hatch was 8 8 However, when the cysts hatching at 5° C were transferred to 21° C the hatch during the next four days was 510 larvæ per 100 cysts, which was almost as great as the hatch for the whole of the previous 62 days During this 4-day period only 2 8 larvæ per 100 cysts emerged from those cysts which were continued at 21° C throughout

These results appear to show that hatching occurs as a result of a rise in temperature after a period at low temperature, results of experiments still in progress agree with this view It has been found, for example, that plants grown in infested soil which previously had been stored out of doors during the winter bore large numbers of mature cereal root eelworm females, while plants grown in the same soil which had been stored at 21° C over winter bore almost none It is possible, however, that the viability of the larvæ had been affected by storage at the higher temperature and this point is being investigated

Clearly, and for the first time, larvæ of the cereal root eelworm have been shown to hatch in response to an external influence The results appear to show that a period at low temperature is essential for the subsequent spring hatch of the cereal root eelworm, and that this occurs in response to a rise in temperature In the field, cysts would not meet the abrupt rise in temperature to which they were subjected in these experiments, nor is it likely that they would ever be subjected to a temperature of 21° C , except perhaps for short periods in the surface layers of the soil It is possible, however, that a smaller rise in temperature may induce hatching, this question is under investigation

Endogone Spores in Cultivated Soils

Using nematological methods of wet sieving and decanting with agricultural soils in Illinois, Gerdemann[1,2] extracted two types of large one-celled spores which gave endotrophic mycorrhiza of the phycomycetous type in inoculated plants The larger of these spores, 183–812µ diam , produced arbuscules but not vesicles in infected roots Clusters of echinulate one-celled spores were formed on external hyphæ[1] A smaller spore, 133–288µ diam , induced typical vesicular-arbuscular infections and, in addition, produced on hyphæ surrounding the roots an *Endogone* sporocarpic stage and chlamydospores[2] The chlamydospores were identical with those extracted from field soil and the sporocarps were similar to those produced by the unnamed mycorrhizal species of *Endogone* described by Mosse[3]

Using the same technique in the examination of cultivated soils from the Dundee area, numerous large one-celled spores have been observed They range in size from 130 to 400µ diam , and also vary in shape, which may be spherical to irregular, or oblong These spores are considered to be either chlamydospores or zygospores of species of *Endogone* When extracted from soil they occur singly (Fig 1) and do not appear to have been formed in sporocarps Samples containing an abundance of spores have also been examined for the presence of sporocarps, but only a few small specimens have been found

The spores can be divided into 6 distinct types which are recognized by differences in average size, in wall thickness and in the morphology of the hyphal attachment In addition, each spore type has a characteristic colour which may be various shades of yellow or brown, and black In some soils only one

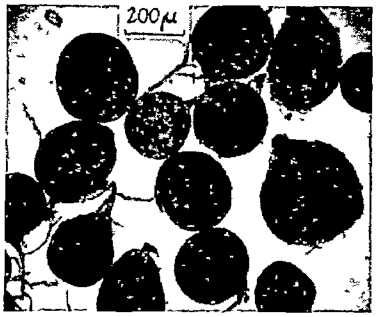

Fig 1 Miscellaneous collection of spores extracted from soil of a wheat field

type of spore is represented In other cases, up to four of the types have been noted in the same sample

Investigations are proceeding to determine whether these spores will induce mycorrhizal infection on various hosts grown in sterilized soil and to determine how many species are represented However, it is now apparent that spores of *Endogone* are abundant in certain cultivated soils These can be detected by direct microscopic examination of soil fractions obtained by wet sieving and decanting and are not revealed by methods normally utilized in soil mycology

MICROBIOLOGY

Inhibition of Endotrophic Sporulation by Antibiotics

ENDOTROPHIC sporulation occurs when an organism forms spores in a medium lacking substances necessary for growth It was of interest to determine whether a group of growth-inhibitory substances also inhibited sporulation

A strain of *Bacillus cereus* var *mycoides* was isolated from soil The organism was grown for 18 hr in shaken flasks at 32° C in a peptone–yeast extract–glucose medium The cells were washed twice in distilled water and suspended at a concentration of 9×10^8 cells/ml in 0 1 *M* potassium phosphate buffer (*p*H 7 4) containing 1 mgm /ml glucose Antibiotics were added in a graded series of concentrations to 10 ml aliquots of cell suspensions and these were then placed in 125-ml flasks and incubated with shaking at 32° C overnight Sporulation was determined by microscopic examination of smears stained with a malachite green spore stain In the controls, greater than 90 per cent of the cells sporulated Where inhibition of sporulation occurred, the minimum concentration of antibiotic that completely inhibited sporulation was then determined

All the antibiotics used were able to inhibit growth of the organism at concentrations below 50 μgm /ml The effect of the antibiotics on sporulation is shown in Table 1 It can be seen that only three antibiotics inhibited sporulation at growth-inhibitory concentrations It is interesting that these three antibiotics, tetracycline, chloramphenicol and erythromycin, are the only ones in the table that are known to act by inhibiting protein synthesis[1].

Table 1

Antibiotic	Minimum concentration to completely inhibit sporulation
Tetracycline	10 μgm./ml
Chloramphenicol	10 μgm /ml
Erythromycin	25 μgm /ml
Penicillin *G*	1,000 μgm /ml
Novobiocin	> 1,000 μgm /ml
Neomycin	> 1,000 μgm /ml
Streptomycin	> 1,000 μgm /ml
Polymyxin *B*	> 1,000 μgm /ml

Concentrations of antibiotic used 1,000, 500, 250, 100, 50, 25, 10 5, 2 5 and 1 μgm /ml

It should be emphasized that the sporulation process is occurring in the absence of growth Several of the other antibiotics listed in the table are known to be active primarily against growing cells, that is, penicillin[2], novobiocin[3], and streptomycin[4]. The present results then seem to confirm that endotrophic sporulation does occur in the absence of growth In addition, these results suggest the value of testing other growth inhibitors for their effects on sporulation, both as an aid in the understanding of the sporulation process, and to help shed more light on the mode of action of antibiotics

Withdrawal of the Concept of the Occurrence of Classical Mitosis in Bacteria

I WISH to retract the concept previously presented by me[1], and to which I have been committed, that classical mitosis occurs in bacteria This interpretation of cytological material was developed on the basis of routine microscopy on stained preparations The configurations observed were interpreted using instrumentation of inadequate resolution to solve the problem of the mechanism of division of this group of organisms It seems likely that this interpretation of structures by white-light microscopy does in fact depend on the presence of not only nuclear material which can assume a multiplicity of forms, but also on the presence of membranous bodies in the cytoplasm which accept stain and at low resolution could be misinterpreted as centrioles The application of the electron microscope in the hands of many others[2,3], as well as more recently by us[4,5], has demonstrated that a classical form of mitotic division in these organisms cannot occur Details of the ultrastructure of bacteria are now becoming resolved, and what is presently known precludes the possibility of a classical mitotic mechanism

It seems appropriate, therefore, on the basis of work of others as well as of ourselves, to acknowledge the error in interpretation which was made, and in so doing perhaps remove some of the confusion in the literature contingent on such an interpretation By acknowledging the error of interpretation, however, I do not mean to imply that I consider that the interpretations of some of my critics concerning the structure of the bacterial nucleus are necessarily correct in the present state of our knowledge There is much yet to be done by means of high-resolution instruments to resolve the ultrastructure of the bacterial cell The work of Kleinschmidt *et al.*[6] is perhaps the most revealing so far, and correlates well with the genetic studies of Wollman and Jacob[7].

It should also be emphasized that much of the work done still remains valid The staining and dehydration procedures[8] developed during these investigations are accepted and used by many as routine[9] More recent efforts at isolation of bacterial nuclei by chemical dissection, as well as the chemical evaluations of the procedures, appear sound[4] Preliminary electron microscopic studies of dissected cells promise to be most revealing[4,5] Electron microscopic studies of the isolated bodies have yet to be completed, and these likewise may contribute to our understanding of the ultimate organization of bacterial 'nuclei' The various suggestive configurations of these isolated bodies as seen by routine microscopy seem likely not to have organizational significance

I am glad of this opportunity to aid in resolving the confusion resulting from the presentation of the interpretation of material with instruments not adequate for the purpose

This investigation was supported in part by research grant *PHS* No *E*–2203 from the National Institutes of Health, U S Public Health Service

PSYCHOLOGY

Effects of Frontal Cortex Lesions on Object Discrimination Learning by Monkeys

For a long time it has been known that monkeys with bilateral dorso-lateral frontal cortex lesions are impaired on delayed response problems At the same time there does not generally appear to be any impairment on visual discrimination learning Recently, Rosvold and Mishkin[1] have suggested that, in certain circumstances, the discrimination learning of monkeys with frontal lesions may be influenced by various preference factors Specifically, Brush *et al* [2] reported that monkeys with frontal lesions are impaired, as compared with intact animals and others with inferotemporal lesions, on a series of object discrimination problems Each individual problem was presented for ten trials Bait was placed under both objects on the first trial of half the problems, and the object chosen by the monkey became the positive (rewarded) cue on the subsequent trials On the first trial of the remaining problems bait was not placed under either object, the chosen object became the negative (unrewarded) cue on the subsequent trials The frontal monkeys were impaired particularly on this latter category of problem—that is, where a reward could be obtained only by responses to the initially non-preferred object It was this finding which led Rosvold and Mishkin to their conclusion that preference factors were an important feature of the frontal deficit

If the performances of frontal monkeys are dominated by stimulus preference factors, then it would be expected that this should become apparent in a testing situation designed specifically to provide data in a form amenable to mathematical analysis of the frequency with which various strategies are adopted Such a method has been described by Levine[3] The experiment described here was undertaken with this object in mind Six young monkeys (*Macaca mulatta*) were tested in a modified version of the Wisconsin general testing apparatus Initially they were trained on three two-choice (simultaneous) object discrimination problems, each problem was run to a criterion performance-level of 90 per cent correct in 50 trials before the next problem was introduced Two of the monkeys then received bilateral ablations of the dorsolateral frontal cortex anterior to the arcuate sulcus Another two received bilateral ablations of the interior temporal cortex It was intended that lesions on both hemispheres should be symmetrical The remaining two monkeys served as intact controls Seven days later the monkeys were retrained on the second and the third of the original problems to a criterion performance level of 23 correct responses in 25 trials

Object discrimination training suitable for detailed analysis then began 16 separate problems were presented during each testing session and each problem was presented for 3 trials On the first trial of half the problems food reward was placed under both cues (first trial positive problems), on the first trial of the remaining problems neither cue was baited (first trial negative problems) During trials 2 and 3 the same reward contingencies held as in the study of Brush *et al* [2] Each testing session contained 8 problems of each type The use of three trials per problem makes the data amenable to the method of analysis suggested by Levine[3] Each pair of cues was drawn at random from approximately 500 multi-dimensional objects bought in Woolworth's and similar stores After each group of 250 problems the objects were re-paired, the only condition being that no pair should appear more than once during the course of the experiment Such 'learning set' training was continued until 1,600 problems had been completed Finally, each monkey was trained on a standard positional 5-sec delayed alternation task until a criterion performance-level of 90 per cent correct responses in 100 trials had been achieved or, if this was not achieved, for a maximum of 1,000 trials

Table 1

Animal	Problem No 1	2	3
Normal No 10	170	82 (0)	0 (0)
Normal No 12	157	117 (0)	18 (0)
Frontal No 8	108	36 (47)	4 (0)
Frontal No 9	390	143 (0)	0 (0)
Temporal No 11	209	123 (23)	45 (21)
Temporal No 13	161	26 (69)	0 (24)

The number of trials required to learn the initial object discriminations are recorded in Table 1, these scores do not include the criterion trials The retraining scores are shown in brackets As would be expected, there was some indication that the temporals were impaired post-operatively Fig 1 summarizes the performances on the 1,600 object discrimination problems Each problem block consisted of 200 problems (100 first trial positive and 100 first trial negative) There is no evidence of any overall frontal impairment Indeed, the performances of the two frontal monkeys were consistently rather better than those of the other subjects The average performance of the two temporal monkeys has been plotted One of these was severely impaired and did not achieve 60 per cent correct responses on any one problem

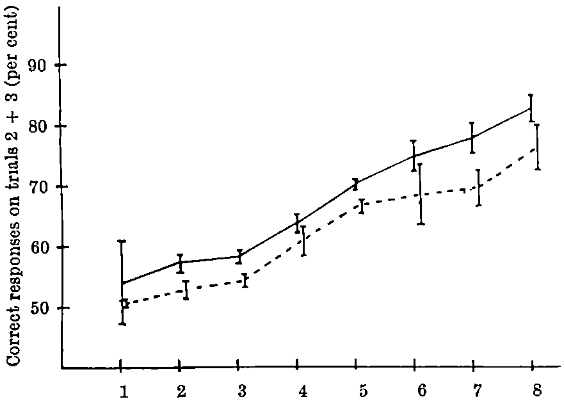

Fig 1 ---, Normals, ——, frontals, , temporals

block However, the other one reached a score of 80 per cent correct on the seventh block

Fig 2 has been constructed from the performances on trials 2 and 3 within each problem block by measuring

$$\frac{\text{(correct responses on first trial positive problems)} \atop \text{minus (correct responses on first trial negative problems)}}{\text{total correct responses}}$$

If the frontal monkeys had been handicapped on first-trial negative problems, this score should have been consistently in the positive rather than the negative range Although this was to some extent true during the earlier problem blocks, there was no evidence to suggest that the frontals differed significantly from the normals A full analysis of the monkeys' performance along the lines suggested by Levine[3] will be published later

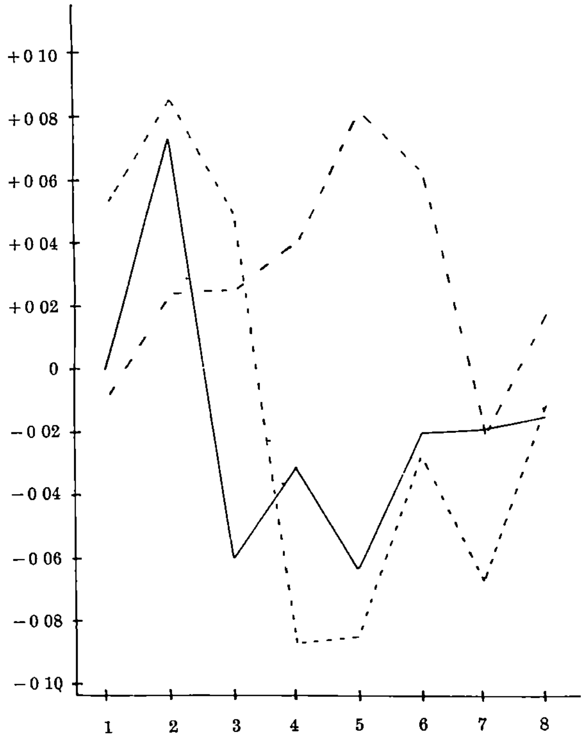

Fig 2 ——, Frontal, No 8, ---, frontal, No 9, , normal, No 10, — —, normal, No 12

Finally, the performance on the delayed alternation task was consistent with previous reports of a frontal impairment on this particular task Neither of the frontal monkeys achieved the criterion within 1,000 trials The scores for the other two groups were Normals, 497 and 117, Temporals, 693 and 111 (criterion trials have not been included in these scores)

There appears to be a discrepancy between the results presented here and those of Brush *et al* [2] It is possible that this might be due, among other reasons, to the difference in the number of trials per problem Although Levine *et al* [4] compared the performances of normal monkeys in situations where the problems were presented for three trials each and where they were presented for twelve trials, and found that the rate of learning set development, considered as a function of the total number of trials, was approximately equal in both groups, this might not apply to frontal monkeys According to a hypothesis recently proposed by one of us[5], frontal lesions may result in an inability to maintain adequate selective attention Along these lines it may be argued that when the cues are presented for only three trials they may retain a degree of novelty value which they lose when they are presented for larger numbers of trials A falling off in the frontals' attention in the latter situation might result in their behaviour deteriorating, one manifestation of which might be the adoption of a stimulus preference strategy This is a primitive response pattern in the sense that both Harlow[6] and Levine[3] have shown that it is particularly liable to occur in normal monkeys during the early stages of learning set development, and is usually eliminated as the training continues

We should like to acknowledge our gratitude to Miss Sheila Hopkins, who tested the animals on the learning set problems, and to Miss Ruth Fishel, who tested them on the delayed-alternation task The research was supported by the U S Air Force under contract *AF* 61 (052)–185 and grant 62–20

Time Uncertainty and the Estimation of Time-intervals

DURING the past decade an increasing number of experimental psychologists have returned to the problems raised by a human subject's reaction-time, the interval between the occurrence of a signal and the initiation of a response to it Many recent investigations, such as those of Klemmer[1,2], Karlin[3], Drazin[4], Bertelson and Boons[5], Kay and Weiss[6], have been concerned with the way in which reaction-time to a signal varies with the duration of the foreperiod, the interval between a warning signal and the signal to respond

As Klemmer pointed out, two different kinds of effect may determine a subject's reaction-time in these situations. The first effect depends on the subject's 'expectancy' that the warning interval will be of a certain length, this being determined by the range of foreperiods used and the probability of particular foreperiods within this range. The second effect depends on the subject's time-keeping mechanism, on the accuracy with which he can estimate an interval of a certain length, when other factors, such as the probability of its occurrence, are held constant. Whereas the first of these effects has been extensively investigated in a recent research, the second has been relatively neglected and there has been little systematic investigation of conditions which influence a subject's accuracy in estimating temporal intervals since Woodrow's[7] work on the "indifference interval".

It has been assumed by most workers that the variability or uncertainty in a subject's estimate of an interval will increase monotonically with the length of the interval in a manner corresponding to the Weber Law, or some variation of it. However, experiments which I recently performed at the Laboratoire de Psychologie Expérimentale, University of Paris, indicate that this is not so and that intervals in the region of 0·5 sec. are estimated with less variability than intervals either smaller or larger than this value. The experiments were also designed to investigate the accuracy with which a subject is able to estimate time-intervals using different rates of counting, and the results showed that a frequency in the region of one count every 0·5 sec. produced much more accurate estimation of longer time-intervals than any other rates either faster or slower.

The experiments were carried out in the following manner. Subjects listened to a regular series of clicks presented by a small loudspeaker, with an interval i between clicks. A series of n clicks was presented and the subject counted these as they occurred. He then had to imagine that the series continued and had to press a key at the estimated moment of occurrence of the $2n-1$th click. In each experimental session the numbers n and $2n-1$ were always specified, and instructions to the subject were of the following form: "You will hear a series of [for example] 5 clicks. Imagine the series to continue and press the key at the moment you estimate the 9th click would have occurred". The error of estimation was recorded to the nearest 1/100th sec. on a continuous pen recorder. In this manner the interval I between the first and last click of the stimulus series should be the same as the interval I' between the last click of the stimulus series and the subject's response. Five values of i (frequency of counting) were used, 0·25 sec., 0·5 sec., 1·0 sec., 2·0 sec. and 4·0 sec., in combination with three values of I, 2 sec., 4 sec., and 8 sec.

Seven subjects attended for three sessions. At each session the various combinations of i and I were presented in random order, and subjects were given practice under each condition before any results were recorded. The final analysis is based on thirty responses for each subject under each combination of i and I.

Typical results are given in Fig. 1, which shows the standard deviations of the estimates of the seven subjects for each value of i when $I = 4$ sec.

Variability in estimation is clearly a minimum when the value of i lies in the region 0·5–1·0 sec. The results for the other conditions are similar except that, when subjects estimate the longest interval $I = 8$ sec. using values of i greater than 2 sec., they tend to interpolate their own count in between the clicks given by the loudspeaker. Hence the value of i does not represent the actual rate of counting for values of i greater than about 2 sec. When subjects did introduce their own method of counting it was again found that the frequency they spontaneously tended to adopt corresponded to $i = 0·5$ sec.

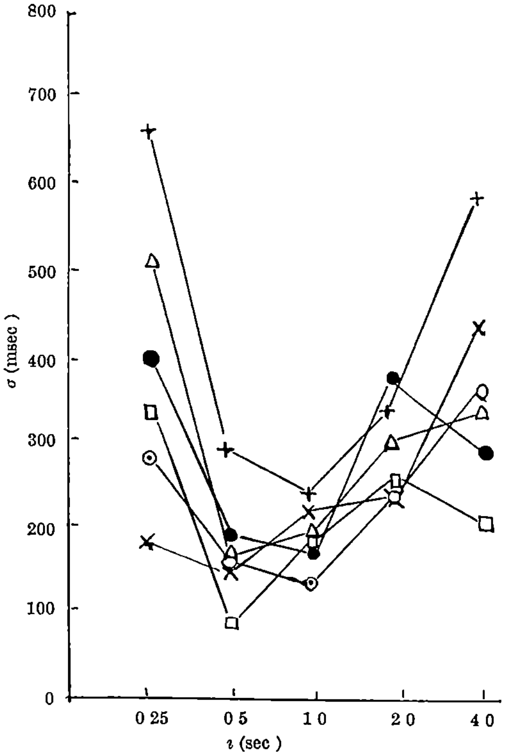

Fig. 1. Standard deviations (msec.) for seven subjects estimating $I = 4$ sec., using values of i from 0·25 to 4·0 sec.

It is worth emphasizing that the values of standard deviation given are absolute not relative values, and that the effect is so marked that, using the optimum frequency, there is less absolute variability in estimating an interval of 4 sec. than there is in estimating an interval of 2 sec. using a non-optimum frequency. Further details of these comparisons will be given by me elsewhere[8].

A general theoretical consequence of these results is that it is most important to take account of the units used, either overtly or implicitly, by a subject when one constructs psychophysical scales by extrapolation or interpolation methods. A practical consequence is that, in tasks having a rhythmic structure, synchronization of a response with an anticipated event should be more accurate at some frequencies than at others. As Fraisse[9] remarks, the value of 0·5 sec. appears in a variety of experiments too often for this to be mere coincidence, but the physiological significance of this value is as yet obscure.

FORTHCOMING EVENTS

Tuesday, July 24

Parliamentary and Scientific Committee, General Committee (in Committee Room 10, House of Commons, Westminster, London, S W 1), at 5 30 p m —Discussion on "Atomic Energy in this Country" introduced by Sir William Cook, Mr A J Sayers and Colonel G W Raby

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned

Sub-Editor (with practical experience of work in medical bibliography and/or scientific publishing, and a wide knowledge of medical terms and accuracy in detailed work) for the *British Medical Bulletin*, for duties which will include verifying references, marking copy for printers and checking proofs—The Director, Recruitment Department, British Council, 65 Davies Street, London, W 1, quoting Ref G3 N (62) (July 27)

Assistant Lecturers or Demonstrators (2) (with medical qualifications registrable in this country) in Pathology—The Registrar, The University, Manchester 13 (July 28)

Lecturer in Geochemistry and Metamorphic Petrology, for duties which will include initiating and administering the geochemical and spectrographic units in the newly completed Sedimentary Research Laboratory—The Registrar (Room 22, O R B), The University, Reading (July 30)

Plant Physiologist (preferably with research experience), for the investigation of effects of temperature, oxygen and carbon dioxide on the respiration of apples—The Director, Ditton Laboratory, Agricultural Research Council, Larkfield, Maidstone, Kent (July 30)

Assistant Lecturer in the Department of Geography—The Registrar, The University, Liverpool, quoting Ref CV/132 (July 31)

Lecturer or Assistant Lecturer in Bacteriology—The Registrar, The University, Manchester 13 (July 31)

Lecturer in Civil Engineering—The Secretary of University Court, The University, Glasgow (August 4)

Associate Professor in the Department of Geography, University of New England, Armidale, New South Wales, Australia—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 (Australia and London, August 11)

Temporary Lecturer in Mathematics (Pure or Applied)—The Principal, Royal Holloway College (University of London), Englefield Green, Surrey (August 11)

Chair of Western Asiatic Archæology at the Institute of Archæology—The Academic Registrar, University of London, Senate House, London, W C.1 (August 15)

Professor of Botany in the School of Biological Sciences, The University of New South Wales—The Agent-General for New South Wales, 56–57 Strand, London, W C 2, and The Appointments Section, The University of New South Wales, Box 1, Kensington, New South Wales, Australia (August 20)

Professor of Zoology in the School of Biological Sciences, The University of New South Wales—The Agent-General for New South Wales, 56–57 Strand, London, W C 2, and the Appointments Section, The University of New South Wales, Box 1, Kensington, New South Wales, Australia (August 20)

Medical Research Fellow (preferably with experience in pædiatrics and nutrition) in the Department of Chemical Pathology, University College, Ibadan, Nigeria, to take part in nutrition studies —The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W C 1 (August 22)

Senior Tutor/Demonstrator (with research interests in socio-economic geography (for preference in the geography of settlement), and preferably field experience in the African or Asiatic tropics) in Geography at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 (Australia and London, August 24)

Lecturer or Assistant Lecturer in the History of Science, and a Lecturer or Assistant Lecturer in Zoology at the University of Singapore—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W C 1 (August 31)

Senior Lecturer in Biochemistry—The Registrar, The University of Adelaide, Australia, or The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 (Australia, August 31)

Lecturer in Veterinary Pathology—The Registrar, The University, Liverpool, quoting Ref No CV/129 (September 15)

Professor and Head (with experience in teaching and research) of the Department of Pharmacy—The Executive Secretary, School of Pharmacy, Hebrew University of Jerusalem, P O Box 1172, Jerusalem (September 15)

Professor of Agricultural Chemistry—J P MacHale, Secretary and Bursar, University College, Earlsfort Terrace, Dublin 2, Republic of Ireland (September 15)

Senior Lecturer (with an honours or higher degree in science or engineering, with teaching and/or research experience in the field of physical metallurgy) in Physical Metallurgy at the University of Melbourne, Australia—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 (Australia and London, September 30)

Assistant Lecturer in Geology—The Registrar, The University, Nottingham

Experimental Officers or Senior Experimental Officers (metallurgists, physicists or physical chemists, preferably, but not essentially, with a degree), for work on direct generation involving cathode preparation and testing—Prof J G Ball, Imperial College of Science and Technology, London, S W 7

Graduate (interested in population genetics, and preferably with appropriate postgraduate research experience), to study the effects of radiation-induced mutations on mouse populations—The Administrator, Radiobiological Research Unit, Medical Research Council, Harwell, Didcot, Berkshire

Lecturer (graduate of a British university, preferably with experience in the field of virology) in Microbiology—The Secretary and Registrar, Bristol College of Science and Technology, Ashley Down, Bristol 7, quoting Ref CST 62/43

Lecturer (with a good honours degree in geology and experience in the application of photogeological techniques) in Photogeology, for undergraduate and postgraduate instruction and research—Prof W D Gill, Geology Department, Imperial College of Science and Technology, London, S W 7

Physics Master—The Headmaster, Carmel College, Wallingford, Berkshire

Research Assistant (graduate chemist or biochemist), to work on problems of protein analysis and structure—The Secretary, St Mary's Hospital Medical School (University of London), Paddington, London, W 2

Research Fellow or Lecturer (mathematical physicist, preferably possessing doctorate) in the Metallurgy Department, for work on problems of crystal plasticity with an established research group—Prof J G Ball, Imperial College of Science and Technology, London, S W 7

Research Physicist (with a higher degree in physics, and preferably experience of high vacuum technique and/or electronic counting equipment) in the J J Thomson Physical Laboratory, to carry out a programme of electron diffraction intensity measurements at high energies—The Registrar, The University, Reading

Research Students in the Department of Chemistry, for research in inorganic fluorine chemistry—Prof Panson, Department of Chemistry, The Royal College of Science and Technology, George Street, Glasgow, C 1

Senior Lecturer or Lecturer in Chemistry, and a Senior Lecturer or Lecturer (preferably with a special interest in geomagnetism or ionospheric physics) in Physics at Ahmadu Belo University, Northern Nigeria—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W C 1

Tutorial Assistant in the Dfpartment of Geology—The Registrar, University College of Wales, Aberystwyth

£500 A YEAR TAX FREE FOR YOUR FAMILY

The Equitable offers you a special plan to protect your family's future at the lowest possible cost Should you die within a period of 20 years your dependants will receive £500 a year tax free for the balance of the period

You only pay premiums for 15 years and if you are 29 now the cost is as little as £18 5 0 a year—about 7/- a week The premiums for larger benefits are in proportion

The Equitable offers attractive terms because it has no shareholders to take any part of the profits and pays no commission for the introduction of business

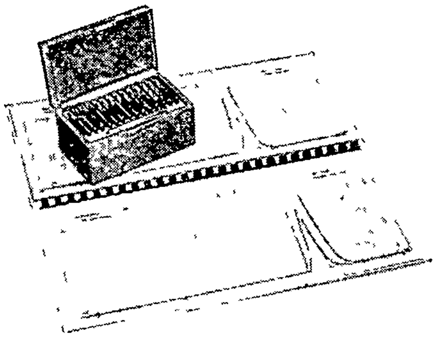
CALIBRATED INTERFERENCE FILTERS

FOR PRECISE SPECTRAL ANALYSIS



Optics Technology MONOPASS interference filters are designed for precise spectral analysis in the 400 millimicron to 2 7 micron region MONOPASS filters permit highly sensitive spectral measurements since each filter passes only an extremely narrow band of wavelengths, and rejects all others from X-band to X-ray Individual calibration curves for each filter assure pinpoint accuracy, with each curve set in laminated plastic and bound in a rugged volume for permanence MONOPASS filters are available in complete sets, or may be ordered to specification

VISIBLE SPECTRUM SET 10A includes ten MONOPASS filters to isolate principal lines as K, Ca, Hg, etc, from 706 millimicrons to 404 millimicrons, important in flame chemical analysis Four neutral density filters and a linear spectral "wedge" filter are included Price, $325 00

VISIBLE SPECTRUM SET 12A includes ten MONOPASS filters uniformly spaced from 400 millimicrons to 700 millimicrons, as well as four neutral density filters and a linear spectral "wedge" filter Price, $325 00

INFRARED SET 15A includes ten MONOPASS filters spaced at every 0 1 micron between 0 8 micron and 1 75 microns Price, $450 00

INFRARED SET 20A includes ten interference filters on 1" diameter substrates spaced at every 0 1 micron between 1 75 microns and 2 75 microns These filters are blocked out to 3 2 microns on the long end and to X-ray on the short end Price, $450 00

NEW! RUBY LASER SET 50A includes seven all dielectric mirrors and beam-splitters at several values of attenuation, designed to withstand high LASER powers without deterioration, plus MONOPASS Filter at 694 millimicron ruby wavelength Price, $350 00

APPOINTMENTS VACANT

UNIVERSITY OF NEW ENGLAND
AUSTRALIA
DEMONSTRATOR IN THE DEPARTMENT OF PHYSIOLOGY

Applications are invited for the above post Applicants with a degree in either Science, Agricultural Science or Veterinary Science will be considered for the position Facilities will be provided for applicants who wish to study for a higher degree The main research interests of the Department are Climate Physiology and Acclimatization Physiological and Biochemical Individuality, Erythropoiesis and Anaemia, and Rumen Physiology Commencing weekly wage will be fixed according to qualifications and experience within Grade I £A 1,120 by £A 60 to £A 1,360, Grade II, £A 1,320 by £A 80 to £A 1,560, or Grade III, £1,560 by £A 80 to £A 1,720 None of these figures include the current cost of living adjustment of £A 44 per annum Tuition fees will be remitted for any course undertaken at the University by the appointee and allowances will be made for travel and removal to Armidale

Applications, two copies, should be forwarded to reach the undersigned by August 10, 1962, and should contain details of academic qualifications and experience, personal data, and the names of two people to whom reference may be made on their behalf, and a recent photograph Applicants outside Australia and New Zealand should forward an additional copy to the Secretary of the Association of Universities of the British Commonwealth, Marlborough House, Pall Mall, London, S W 1, by the same date

T C LAMBLE,
Registrar

Armidale, N S W,
Australia

UNIVERSITY COLLEGE OF NORTH WALES
BANGOR
DEPARTMENT OF AGRICULTURAL BOTANY
RESEARCH ASSISTANTSHIP ON SILICA UPTAKE BY PLANTS

Applications are invited from graduates in agricultural botany, botany, biochemistry or agricultural chemistry, with interests in plant physiology or anatomy, to undertake research on silica uptake and deposition by grasses Salary, £550 by £50 to £650 and F S S U benefits

Applications (two copies), giving full details of education and previous experience, together with the names and addresses of two referees should be addressed to the Registrar University College of North Wales, Bangor, to arrive not later than August 8, 1962

UNIVERSITY COLLEGE, DUBLIN
ASSISTANT IN AGRICULTURAL ECONOMICS
(SESSION 1962-63)

Applications are invited for an Assistantship in Agricultural Economics for Session 1962-63 Candidates should have an honours degree in economics or in agricultural economics Some experience of teaching is necessary as the successful applicant will be required to lecture on agricultural economics to final year undergraduates (agricultural) Salary £900 to £1 100 per annum, depending on qualifications and experience Marriage and children's allowances payable

Applications, in writing, giving full details to Professor of Farm Management, University College, Glasnevin, Dublin, 9

NATIONAL INSTITUTE FOR RESEARCH IN NUCLEAR SCIENCE

Opportunities for Experimental Physicists at the Rutherford High Energy Laboratory, Harwell

RESEARCH IN ELEMENTARY PARTICLE PHYSICS

The 7 GeV proton synchrotron "NIMROD" which is being built in the Rutherford High Energy Laboratory, Harwell, will be in operation by the end of 1963 There are available a limited number of posts for physicists with postgraduate experience in the field of elementary particle physics or allied subjects to join teams now planning and preparing the experimental programme

The posts are offered with a tenure of up to five years and carry F S S U benefits Applicants would be expected to hold a higher research degree or to have had the equivalent amount of postgraduate research experience

The annual salary depending on age and experience, will be within one of the following ranges

£ £
790 to 1,310
1,440 to 1,770
1,840 to 2,590

Assistance could be given with housing or house purchase There are generous leave arrangements

If you are interested in a post now or during 1963 please send a postcard for an application form to

The Personnel Officer,
The National Institute for Research in Nuclear Science,
Harwell, Didcot, Berkshire, *quoting reference number A6/34*

UNIVERSITY OF MANCHESTER

Applications are invited for the post of Assistant Lecturer in the Department of Metallurgy of the Faculty of Science Candidates should be graduates in Metallurgy or Chemistry, with practice or a direct interest in the application of thermodynamics and chemical kinetics to chemical reactions of metals, alloys, and their compounds A vigorous research programme already exists in the vapour deposition of metals and the oxidation of metals and alloys Duties to commence October 1, 1962, or as soon as possible thereafter Salary scale £900 to £1 050 per annum with membership of the F S S U and children s allowance scheme

Applications should be sent not later than July 31, 1962, to the Registrar, the University, Manchester 13, from whom further particulars and forms of application may be obtained

NATIONAL COLLEGE OF FOOD TECHNOLOGY
ST GEORGE'S AVENUE, WEYBRIDGE SURREY
Principal J D Mounfield, M Sc Tech, Ph D, F R I C

Applications are invited for the post of Lecturer in the College from graduates in chemistry, preferably from those with experience in the food industry The duties will include the teaching of chemistry and food quality control Salary scale £1,600 by £40 to £1 800 per annum Starting salary dependent on qualifications and experience

Application forms (obtainable from the College), should be sent to the Principal as soon as possible

UNIVERSITY OF MANCHESTE

Applications are invited for the post of
turer in the Department of Metallurgy of
Faculty of Science Candidates should be gr
ates in metallurgy preferably with some indus
or research experience in the field of enginee
applications and/or properties of metals, all
their oxides or carbides The successful ca
date will be expected to undertake research
problems of materials and to assist in the te
ing of metallurgical principles to enginee
and/or dental students Salary on a scale fi
£1,150 to £1 950 per annum, initial salary acc
ing to qualifications and experience Meml
ship of the F S S U and children's allowa
scheme

Applications should be sent not later than
31, 1962, to the Registrar the University, M
chester, 13, from whom further particulars
forms of application may be obtained

BOARD OF MANAGEMENT FO
DUNDEE GENERAL HOSPITAL
ASSISTANT BIOCHEMIST

Assistant Biochemist with a degree in ch
istry or biochemistry, or Membership of
Royal Institute of Chemistry, required for
of the main Teaching Hospitals of the Univer
of St Andrews The appointee will be requ
when trained, to assist in the supervision of w
in other hospitals in the Eastern Region of Sc
land Salary in the range of £650 to £1,
(basic grade), the starting point depending
qualifications and experience Excellent opp
tunities for further training

Applications together with the names of t
referees should be sent to the Hospital Secreta
Maryfield Hospital, Dundee

Kodak High Speed Ektachrome—fast becoming invaluable in many research projects...

High Speed 'Ektachrome' is the fastest colour film made by Kodak. Rated at ASA 160, it brings black-and-white speed to colour photography. It has proved itself invaluable where coloured dyes are used as markers; in metallurgical analysis by flame propagation; in photo-recording where high-speed galvanometer traces overlap and need to be identified by colour; in photo-elastic stress analysis; in Schlieren photography and in many other fields where high speed transients and identification by colour go together. WRITE FOR DETAILS

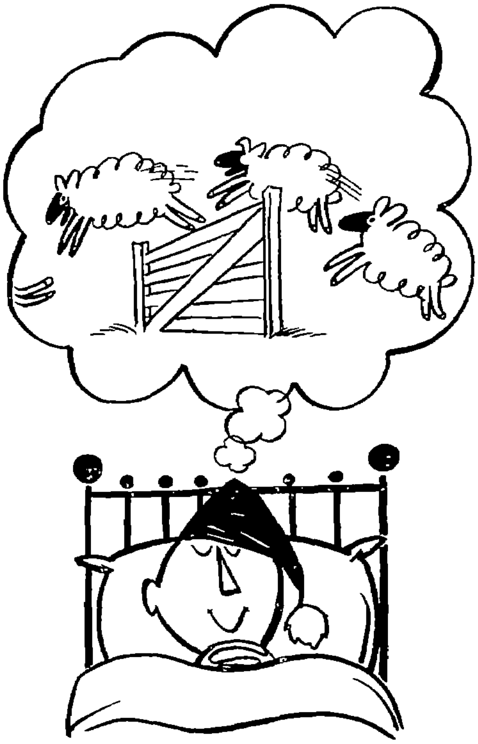
COULTER COUNTER



Counting and sizing with Coulter is anything but a tiring business and you can sleep peacefully in the knowledge that you have the most advanced equipment for this exacting work. The Coulter Counter is based on the simplest possible principle and manufactured to the highest standards. The result is an exceptionally accurate instrument with a high degree of calibration stability. It will count and size at least twenty times as fast as any other method without any operator fatigue and without any calculations more complicated than simple arithmetic.

- **Counts up to 5,000 particles per second**
- **Sizes from 0.25 microns upwards**
- **Wide size range (1:64000 Volume ratio)**
- **Complete size distribution analyses made in under 1 hour**
- **On-Stream quality control possible**

full details will be sent on request

TECHNICAL TRANSLATING

TECHNICAL translating must be regarded as a regrettable necessity If scientists knew their languages, or if translators knew their science, there would be no problem As matters stand, however, the flood of technical and scientific literature in all languages continues unabated, and the problem has been solved to date by producing a limited number of cover-to-cover translations from Russian into English and leaving all other articles and papers to the individual interest of scientists who can request translations privately

In this way the Copyright Act of 1956, which lays down that translating is legal only when done with the author's consent, is obeyed in the spirit and there the matter might rest were it not that in the final analysis technical translating is an essential service to scientists and should be improved within the limits of the possible

Staff translators can get help from their colleagues, and free-lance translators and translation agencies manage with their given resources, but officially no questions are asked whether the services provided as a whole are good enough Technical translators generally do not seem to appreciate that the literary aspect of their work should be subordinated to its technical aspect An expert translator in his particular technical field knows only too well how complex the subject-matter usually is and thereby does not throw the onus of understanding entirely on the reader, but the technical or scientific worker has in far too many cases to be extremely indulgent in puzzling out possible meanings in what passes for a technical translation

Provided a technical translator has had the necessary training and is sufficiently acquainted with the details in the two relevant languages, the translation itself should only be in plain technical English, which should be regarded as the professional standard to be aimed at in this kind of work The alternative —that scientists should learn languages and do their own foreign reading—is interesting in theory and would naturally broaden their cultural outlook, but in practice the vast majority of scientific workers will always have to rely on the help they can get from technical translators Another point is that translations in their nature are expensive It would therefore be in the interest of everyone concerned to see that a professional level were reached and possibly taken for granted

A step in this direction would be for some authorized and recognized body to produce a publication similar to *Technical Translations*, a fortnightly typescript-offset journal published by the U S Department of Commerce, Office of Technical Services, Washington, D C , at the reasonable price of 12 dollars per annum inside the United States (16 dollars abroad) The value of such a British *Technical Translations* would lie in the co-operative effort required to bring all the translators and translation agencies in Great Britain under one umbrella so that the service given to scientists and technologists would be no less prompt and comprehensive than that given to their colleagues in the United States

Translations not only have to be made, they also have to be made accessible

The difficulties of educating technical translators, however, should not be underestimated It takes years to learn science, and equally years to learn languages It follows, therefore, that technical translators cannot change or be produced overnight Similarly, it follows that if no academic courses of a suitable nature are provided, there will never be enough trained technical translators to do the work in the future, even if the demand for good workers does not increase

The Fédération Internationale des Traducteurs in Paris is drawing up a 'Translator's Charter' which is intended to put all translators, technical and literary, on a professional basis internationally, and the Institute of Linguists, 3 Craven Hill, London, W 2, is preparing plans for a diploma specially for technical translators in Britain It remains to be seen whether these measures, taken by themselves, will be sufficient to satisfy the demand for a rapid and accurate communication of technical and scientific papers published in languages other than English

The following suggestions, therefore, are put forward as a contribution to the study of a problem which perhaps deserves far more attention than it has so far received

The objective should be two-fold to provide courses for beginners and short refresher courses for practising translators All this would take time, but only a limited number of people would be involved, otherwise there might be a flood of translators to cope with a possibly static amount of work

Courses for beginners should be relatively easy to organize as the requirements would involve only basic languages and basic science or technology The Holborn College of Law, Languages and Commerce, Red Lion Square, London, W C 1, is running at present a German technical translation course and will have in the autumn also a similar course in French, while the Institut Français, Queensberry Place, London, S W 7, is offering a French technical translation course now

By adopting a scheme with a high-sounding title such as industrial scholarships, it might also be possible to transfer from the universities direct to industry a limited number of talented graduates who would rather combine science and languages than do either separately Again, the idea of industrial scholarships would have to come preferably from large firms or an organization such as the Federation of British Industries

With regard to refresher courses, translators need to keep up with the advancing terminology and developments in the scientific and technical fields every bit as much as their practising opposite numbers, that is, their potential clients Annual weekends could meet this requirement if the necessary backing from authoritative quarters were forthcoming The subject-matter for such refresher courses is more or less well known to every technical translator techniques and jargon

Beginners must naturally keep strictly to the original, but with experience a certain latitude becomes possible and desirable For example, every language has its typical grammatical constructions Normally, translating is done word for word with the minimum of rearrangement to give adequate readability Perhaps more acceptable results could be achieved faster if translators regarded it as part of their task to translate also grammatical constructions The substance of the original may come through even more clearly in this way

Another technique which sounds scarcely relevant, but is extremely important from a practical point of view, is typing The better a translator can type, the more time and energy he has for the actual work of translating A quarter of an hour, or even longer, looking for the right word is most uneconomical working, yet it is so easy for one translator to phone another who knows the answer and might reciprocate on some future occasion

The image of technical translating is small, pettifogging and 'uninteresting' All this it certainly is on occasion, especially when output alone is important for economic reasons.

In the wider picture, however, science and technology have many important small links in the chain from the original conception to the final achievement, whatever it happens to be, and technical translating is one such link in the information and communications field Perhaps this link is a more vital one than is generally appreciated because, in the past, too many amateurs have had to do it or it would, by and large, not have been done at all

THE SECOND MASER MILESTONE

Advances in Quantum Electronics

Edited by Prof Jay R Singer. Pp xvii+641 (New York and London Columbia University Press, 1961) 15 dollars, 120*s*

THE title of this book rather suggests that it is a comprehensive review of the present state of quantum electronics, and so it is, for the expert

The new field of quantum electronics was firmly established at its first international conference, held in September 1959 The second international conference was held in Berkeley, California, in March 1961, and the present volume is really the conference report It comprises the summaries and parts of the discussions of about seventy papers presented at the meeting The articles vary in length from a few paragraphs to about ten pages, depending presumably on the whims of the authors, and their contents are usually devoted to areas of the subject where recent advances have been made, with relatively little space devoted to giving the background of the topic Thus the book must be regarded as primarily for the worker in quantum electronics, and a newcomer will probably wish there were more review articles Even so, a casual reader can scarcely fail to be impressed by the picture which emerges, of a most exciting and rapidly developing field of activity.

It is natural to compare this book with the report of the first conference, published under the title of *Quantum Electronics* and edited by Dr C H Townes, to see how the ideas and work there reported have progressed Two main features emerge In 1959 it was rather novel to have a microwave amplifier or oscillator using the maser principle, but now this is so commonplace that relatively little space is devoted to masers The big step forward has come with the application of maser principles to optical frequencies, and has led to the laser, or the generation of coherent infra-red and visible light From the high proportion of papers devoted to lasers it is clear that interest has now swung away from microwave masers, for the very good reason that the new field provides all sorts of challenging problems and exciting possibilities To mention a few there is the possibility that modulated visible light can be used for communication purposes both terrestrially and in outer space, so intense can be the radiation from a laser that a wide variety of second order effects may be observable, such as the generation of higher harmonics of optical frequencies, and the production of far-infra-red radiation by the mixing of two optical frequencies, alternatively, just the study of the effects produced by subjecting materials to intense radiation fields should in itself be of considerable interest All these possibilities and many others were discussed at the conference, and there are papers describing the present state of progress As no developments of this magnitude can take place without accompanying advances in techniques there are papers dealing with all aspects of laser technology. materials, light sources, optical systems and so on But in nearly every case the relevant paper is short, and probably omits as much as it reveals

One section is entitled, "Some New Ideas and Accomplishments" I would have thought that these sentiments should have applied to the whole volume, and its publication will be widely welcomed by the considerable number of physicists and electronic engineers who are at present exploiting the field of quantum electronics K W H STEVENS

ASTRONOMY IN EVOLUTION

A History of Astronomy

By A Pannekoek Pp 521+24 plates (London George Allen and Unwin, Ltd , 1961) 65*s* net

THE main problem facing an author attempting to write about the history of any science is to decide on the amount of detail which should be included, too much detail and the reader loses the main gist of the story, too little and the story tends to become a string of generalizations The result must always be a compromise and especially is this so in a history of astronomy which must go back before the beginnings of civilization and the advent of written records The late Prof Pannekoek, well known as a practising astronomer, has managed to steer a middle course between too many facts and too much generalization On this important criterion his book scores a considerable success

Yet a balance between fact and general assessments is not enough, for the facts must be correct, there must be no gaping lacunæ and the historical generalizations should fit the evidence presented On the facts themselves, Prof Pannekoek is sound enough, even if occasionally an oversimplification tends to give one a wrong impression, and there are certainly no major omissions to be laid at his door. It is through some of the paragraphs giving the author's historical interpretations that the reader should, however, be prepared sometimes to tread rather warily, in a number of instances there is more than a tendency to apply a mid-twentieth century attitude in assessing the reasons for failures or changes made long before the Renaissance of Western Europe had come to alter men's outlook Yet these occur mainly in the earlier part of the book, and, in any event, they never amount to serious proportions

Prof. Pannekoek laid out the general scheme of his book in a thoroughly sound way, dividing it into three parts The first of these—astronomy in the ancient world—is concerned with the very beginnings of the subject from prehistoric times until the fifteenth century A D when Ulugh Beg made his famous star catalogue at Samarkand This occupies less than a third of the book The second part—astronomy in revolution—commencing with brief chapters on what is called "Dark Europe" and the renascence of science, passes on to discuss the contributions of Copernicus, Brahe, Kepler, Galileo and Newton New observational accuracy following on the invention of the telescope and refinements to celestial mechanics consequent on the application of gravitational theory bring the section to a close The ground is now prepared for part three which, beginning with the extraordinary observations of William Herschel, is concerned with the stellar universe With the title "Astronomy Surveying the Universe", the reader is brought, if not up to date, at least well into the twentieth century, and there is a brief mention of the work of Eddington and Einstein.

Prof Pannekoek shines most in the third part, when he deals with the more modern aspects of astronomical history In the second part, the era of dynamical and telescopic astronomy, his magnitude is scarcely perceptibly dimmed, and it is only in the first part of the book, when he deals with ancient astronomy and those whose outlook did not include any truly empirical approach, that he becomes partially eclipsed from time to time Clearly, his sympathies grow in inverse proportion to the time difference between his own age and that with which he is dealing Strange to relate, it is in the first part of the book that he expresses his willingness to believe that the Babylonians and others since their day were able to see the crescent of Venus with their eye alone and that even the satellites of Jupiter have been observed in this way such observations are equivalent to being able to read from a distance of more than 32 ft the sans serif capitals at the top of this review! No, Part 1 is not the happiest feature of the book, although it certainly contains a wealth of interesting and useful material.

Prof Pannekoek's book appeared first in 1951 in Amsterdam and the fact that it contains no reference to the steady-state theory is not, then, a cause for adverse comment, nor is the complete omission of radioastronomy Unfortunately, readers may nevertheless feel surprised, at least over radioastronomy, as the publishers in their wisdom have inserted a photograph of the 250-ft parabola at Jodrell Bank They must, however, assuage their disappointment by reading the useful appendixes or referring to the very full list of references It is also sad to record that the translation of Prof Pannekoek's original text is not all it might be indeed, at least two translators seem to have been at work, one whose style is far more pedantic than the other In consequence, tortuous sentences and infelicities of phrase which are not conducive to relaxed reading are all too frequent, but in spite of this, the book is something which can do no less than add to what was already a very worthy reputation COLIN A RONAN

REACTOR MATERIALS AND RADIATION DAMAGE

Properties of Reactor Materials and the Effects of Radiation Damage

Proceedings of the International Conference held at Berkeley Castle, Gloucestershire, England, from 30th May to 2nd June, 1961 General Editor D J. Littler (Central Electricity Generating Board: Berkeley Nuclear Laboratories) Pp xv + 562. (London Butterworth and Co (Publishers), Ltd, 1962) 126*s*

THIS book is a report of a conference held in May 1961 to mark the opening of the Berkeley Nuclear Laboratories of the Central Electricity Generating Board One hundred and fifty delegates were invited, and forty-seven papers were presented. There were three introductory lectures F Seitz spoke on the point defects introduced by irradiation, but as his lecture was based on work already published a summary only is given A H Cottrell summarized the theory of fracture, and L Rotherham gave an interesting account of the history of pile design and of the materials problems that arose in the development of the British gas-cooled reactors. The main Conference was organized in nine sessions, and dealt with the measurement of neutron flux in reactors, the theory of damage and the direct and indirect experimental methods used in its study, the effects of irradiation on mechanical properties and resistance to corrosion, and the phenomena of growth and swelling in reactor materials The term 'growth' was applied to the changes of shape and dimensions produced by thermal cycling and by the production of vacancies, interstitials and fission fragments within the material, while the term 'swelling' was confined to the effects of the generation of insoluble gases within the material, though the distinction was not always consistently maintained The papers were discussed in groups, the discussions were lively and informative they are fully reported but well edited The book as a whole is well printed and illustrated, and pleasant to read

The book does not really live up to its title, for it does not present a logical account of the properties of reactor materials in relation to their function in the reactor Questions of neutron absorption, and the conflict that so often arises between desirable nuclear properties and undesirable mechanical and chemical properties are scarcely mentioned Instead, a discussion of present knowledge and theories of radiation damage is presented Consequently, the book is immediately useful to the specialist concerned with the day-to-day handling of these problems rather than to the general reader. In due time it will be frequently used to discover what was thought about these subjects in 1961.

The picture is one of great activity and some confusion. The methods of calculating or measuring the neutron fluxes within a reactor are not yet finalized, so that it is still better to state that a sample was exposed for a given time at a certain point in a certain pile, with an estimate of the flux, than simply to give a figure for the total flux. A variety of direct methods for observing the effects of radiation damage have been developed, but often only the results of a few preliminary observations were available, showing that the method has promise. It is, however, apparent that the electron microscopy of thin films is a powerful method, and that much is to be gained by its use for observations of specimens systematically exposed to accurately measured and closely defined radiations.

The important practical problems included the structural changes and loss of strength in irradiated graphite and the release of the stored energy on heating, the hardening and changes of creep and fatigue strength in canning materials, the possibility of radiation increasing the chemical reactivity of graphite towards the constituents of cooling gases, the swelling and embrittlement of boron-containing control rods, and the control of swelling and distortion in uranium and uranium alloy fuel elements. The embrittlement of ferritic pressure vessel steels did not receive as much attention as might have been expected, but there was some discussion of the relation between twinning and the initiation of cleavage fracture in iron. A number of papers aimed at the elucidation of the physical processes associated with radiation damage but experiment yielded enough incalculable results to show that the processes are not yet understood, and that theory must for some time depend on the guidance of experiment.

Most of the papers were highly condensed, and some of them were written in a breathless shorthand, unnecessarily difficult for the reader. The authors of these papers would do well to study the Russian contributions, which were generally models of courteous and lucid English. N. P. Allen

POLITICS OF AGRICULTURE

The State and the Farmer

By Peter Self and Prof. Herbert J. Storing. Pp. 251. (London: George Allen and Unwin, Ltd., 1962.) 30s. net.

The Economics of Subsidising Agriculture

A Study of British Policy. By Gavin McCrone. (University of Glasgow Social and Economic Studies, New Series, No. 1.) Pp. 189. (London: George Allen and Unwin, Ltd., 1962.) 25s. net.

POLITICS 'contains' economics in the same sense that medicine contains pharmacology, or agriculture contains veterinary science; each of the latter sciences constitutes a legitimate branch of knowledge in its own right; but the actual application of the conclusions reached by these sciences can only be made by the legislator, the physician and the farmer, respectively (together with the scientists who advise him). These latter are synthesizers, who have to take into account the evidence from a variety of contributory sciences before they reach their conclusions.

So the economist must not claim priority; and it i philosophically correct to regard agricultural economics as a contributor of only part of the knowledg required for the solution of the problems of agricultural politics, the subject-matter of *The State and th Farmer*.

Peter Self, lecturer in political science at th London School of Economics, has mainly made hi name as a far-seeing writer on the acute problems o town planning and urban expansion; in this book collaborating with an American professor, he enter quite a new field. The book covers the subject mos comprehensively; I have searched diligently for th smallest inaccuracy, without success; the authors g out of their way to be scrupulously fair to ever party concerned; and all this is done without an sacrifice of the ease with which this book can b read, a most unusual feat in writing. My only complaint is that the study might have gone back a littl farther into history to mention Lloyd George's *Green Book* of 1925, which proposed all the ideas—security of tenure, low rents, and guaranteed prices—which were to become the policy of both the Conservativ and Labour Parties in the 'forties.

The essence of the book is a fascinating and rather alarming account of the extraordinary skill with which the National Farmers' Union was organized—"losing battles to win campaigns" as a political pressure group, to obtain such large concessions from a predominantly urban parliament. Governments of both parties were afraid of an open breach with so well-organized a minority.

In return for all these concessions, the Government took power to expel farmers judged incompetent from their farms and homes. The National Farmers' Union had no qualms about the Englishman's home no longer being his castle, and indeed protested when the Government repealed these powers in 1958. Attempts to exercise these powers had in fact been few and half-hearted. However, the decision to repeal them, the authors think, must be attributed to the hostile publicity so brilliantly planned by a small group of Liberal farmers, the Farmers' and Small Holders' Association.

The authors are moderately critical of the administration of these Acts by the Civil Service (as in the Crichel Down case), and by War Agricultural Committees, in which 'muddle' and 'gossip' too often took the place of efficiency and justice. However, they defend the Government, and criticize the Farmers' and Small Holders' Association, over the notorious case of the expulsion of Lady Garbett.

The National Farmers' Union, as *The State and the Farmer* points out, has always been impatient of political claims based on the preservation of farming as a way of life for those deeply attached to it, and of the beauty of the English countryside—though it is here, in fact, that the real strength of the Union's claims lies. It has always contended that its case was strictly economic, namely, the improvement of Britain's balance of payments by replacing imports. McCrone meets this claim head on. He argues the case in technical detail, but his central point, which is valuable and important, is that the imports displaced have been mainly from the Commonwealth (including some poor sugar-producing communities) and Denmark, all very good customers for British manufactures. Their economic situation requires that, when Britain buys less from them, they must, on the whole, react by buying less from Britain. Indeed, they go out of their way to foster new manufacturing capacity in order to make sure that they buy still less from Britain in the future. Meanwhile, the expansion of high-cost production of milk and pork in Britain has greatly increased imports of fodder grains, most of which come from the dollar area. Much of the grain fed to dairy cows, it appears, is wasted, but the author evades discussion of this question.

The author did some original calculations, comparing the price support received by farmers in European countries measured as a percentage of their gross sales, with Britain third on the list at 24 per cent (only Switzerland and Finland are higher), Germany 18 per cent, France 15 per cent, and the other Common Market countries lower again. If we reckon on 'net sales' (that is, excluding imported fodder grains and store cattle) the British proportion would come out very much higher again. Neglect of this point leads McCrone into a really serious error (although a great many others have fallen into the same error, including Government spokesmen) when he claims that British agriculture produces 43 per cent of the country's requirements. Debiting imported fodder and stores, the correct figure for home production as a proportion of all agricultural requirements is only about 25 per cent (a little higher if tropical products and textile fibres are omitted).

He is also wrong when he asks us to "take a look at farm buildings"—after all the tax-aided farm building of the past decade it is now probably true to say that too much money has been spent on farm buildings rather than too little.

Finally, however, the author has the courage to make himself unpopular by challenging the principle of security of tenure. Was it not precisely the lack of this security, he asks, which provoked so many important agricultural improvements in the eighteenth and nineteenth centuries? COLIN CLARK

FOOD SCIENCE

Recent Advances in Food Science

Papers read at the Residential Summer Course, Glasgow, September 1960. Edited by Prof. John Hawthorn and Jas. Muil Leitch. Vol. 1: Commodities. Pp. xv+284+xvi. Vol. 2: Processing. Pp. xv+317+xvi. (London: Butterworth and Co. (Publishers), Ltd., 1962.) 70*s.* each volume.

THE acceptance of the term 'food science' effectively dates from the publication in 1951 of the papers presented to the short courses in food science held by the Low Temperature Research Station in Cambridge. The volumes under review result from a residential course on recent advances in food science held at the Royal College of Science and Technology in Glasgow in 1960.

The 54 papers are separated into two volumes entitled *Commodities* and *Processing* respectively. Volume 1 is divided into three sections, and the first introductory one contains an article on teaching and research on food science in the United States by Prof. E. M. Mrak of the University of California, who acknowledges the great contributions made by British scientists in this field. Three papers follow on food and micro-organisms where, after general considerations by Prof. J. Hawthorn and a review of the effects of environment on the growth of micro-organisms by Prof. E. O. Morris, there is a discussion by Prof. J. W. Howie on the hazards of handling unclean food, that is, food poisoning, where he shows that *Salmonella typhimurium* is, at least in Great Britain, by far the most important disease-producing organism.

Section 2, entitled "Animal Foods", contains 13 papers and deals with such topics as the anatomical distribution of edible tissues (R. W. Pomeroy), adipose tissue and animal lipids (C. H. Lea), the physiology of milk secretion and its relationship to milk composition (J. A. B. Smith), some physical, chemical and structural characteristics of egg shells (C. Tyler), the bacteriological and chemical changes in spoiling fish (J. M. Shewan) and autolytic changes in the lipids of fish flesh (J. A. Lovern).

The final section of Volume 1 is entitled "Vegetable Foods" and consists of papers on polyphenols (E. C. Bate-Smith), wheat proteins (J. Pace), wheat lipids (N. Fisher), malting (I. A. Preece), cereals other than wheat and barley (W. F. Geddes) and fresh fruit and vegetables (J. C. Fidler).

Volume 2 starts with a comprehensive paper on the accelerated freeze-drying process by J. C. Forrest, who lists some of the features worthy of further study which could not be completed owing to the closure of the experimental factory of the Ministry of Agriculture, Fisheries and Food at Aberdeen. The author of the second paper, E. G. B. Gooding, was also prominent in the research programme of the Aberdeen factory; he contributes a discussion on the effects of storage on the quality of dehydrated foods, especially vegetables. Deterioration of dehydrated meat is considered in two further papers; the first, by Dr. Matheson, demonstrates the presence of enzymes after freeze drying, but states that their importance in the rapid deterioration of products above certain moisture-levels has not yet been proved. The second is a consideration of non-enzymatic browning in dried meat, very clearly presented by Dr. J. G. Sharp.

In a section on sterilization and refrigeration, heat sterilization (T. G. Gillespy), sterilized milk (H. Burton and D. J. Jayne-Williams), modern cans (R. K. Sanders) and processing and canning machinery (T. W. Uthwatt) are considered. The preservation of fish at sea both by chilling and freezing is discussed by G. C. Eddie with considerable attention to its engineering and economic aspects. This is followed by a general consideration of quick freezing of fruits and vegetables (W. B. Adam) and an extremely interesting paper on pre-cooked frozen foods (J. H. Hulse) especially with regard to present practice in North America. This is a field in which the author predicted the great expansion that is now taking place in Britain.

The remainder of the volume contains a group of papers on such varied topics as cheese starters (R. J. M. Crawford), egg preservation (N. R. Knowles), new developments in milling processes (C. R. Jones), continuous baking processes (J. J. Devlin and N. Chamberlain), sugar preserves (Mamie Olliver) and the bacteriology of meat-curing brines (M. Ingram).

It is of interest that after all the great hopes expressed for radiation preservation of food only a few years ago there is not a single paper devoted to this subject; however, the subject is referred to in the text by three authors.

The volumes can be thoroughly recommended to all interested in recent developments in food science as being the most up-to-date collection of information available on a wide series of topics in this rapidly developing field. P. L. PELLETT

WILLIAM HENRY BRAGG AND THE NEW CRYSTALLOGRAPHY*

By Prof. P. P. EWALD, F.R.S.

President of the International Union of Crystallography

THE year 1962 has a double significance in crystallography. It is fifty years since Max von Laue's discovery of the diffraction of X-rays in crystals, the basic venture that detected the port of entry to the New Crystallography, and it is a hundred years since the birth of William Henry Bragg, the older of the two pioneers who together were the first to find the path to the riches of the untrodden land lying behind the coast. It follows by simple arithmetic that William Henry Bragg was fifty years of age when he began the work that makes his and his son's name famous as long as our present science will persist. This is, in itself, an unusually high age for discoveries of prime importance in physics, but even more remarkable is the continuous hold of leadership in the new research which W. H. as well as W. L. Bragg have maintained—Sir William up to the last months before his death at the age of eighty, and Sir Lawrence, fortunately, to this day, and, we hope, long beyond.

The title of the lecture makes mention only of William Henry Bragg, because he is distinguished, this year, by the centenary of his birthday. Yet, so far as the work on the new crystallography is concerned, the contributions of father and son are interlinked to such an extent, especially in the early years, that it would be an invidious attempt to single out one or the other.

Let us now go back a long stretch of time in order adequately to describe the setting of the early and most dramatic work of the Braggs in the tension-loaded years of 1912–14. It is hard for the present generation of scientists, be they advanced or still budding, to keep in mind how many facts which now belong to our well-established picture of the physical world were either quite unknown or very hypothetical in 1912, the year of Laue's experiment. The atom, far from being represented by the simple and well-established present model, was still a nebulous entity in 1912 about which nothing decisive was known. Rutherford's model, it is true, had been announced the year before as an alternative to J. J. Thomson's entirely different conception of the atom, but it had yet to be established on more evidence than that of the scattering effect on α-particles. No convincing quantitative connexion to the mysterious Rydberg number had yet been found—this amazing feat was to occur only in the next year, 1913. The quantum of action, represented by Planck's constant *h*, had made its first appearance in Planck's theory of black-body radiation in 1900, but up to 1912 it remained an *ad hoc* hypothesis which most of the physicists who were steeped in classical physics regarded as a temporary impasse which might soon be solved by the invention of a better model.

There existed, thanks to Clausius, Maxwell and Boltzmann, a fairly satisfactory model of matter in the gas state, but for the more individualistic aggregations, solid and liquid, scarcely anything was known. We can perhaps best visualize this vagueness of knowledge by considering how little detail is known even to-day of the liquid state: one is still at work trying to find out what are the fundamental features of the structure of a liquid which determine its physical properties. It was the same with crystals before 1912. An elaborate theory of crystal structure had grown from the very beginnings of quantitative measurement of crystals about 1781 and had, somewhat more than a hundred years later, led to a highly perfected, complete, but rather abstract theory of space groups which has now found its right place, but which at the time we are speaking of was void of any but the most formal connexion to the problems of solid matter. No physicist, no crystallographer was able to assign correctly to a given crystal one, or even a small selection, of the 230 possibilities of arrangement which this theory predicted, and it was left wide open for discussion what was the nature of the particles that were arranged in the three-dimensionally periodic fashions which the theory allowed: individual atoms, molecules, characteristic little crystal fragments?

The attempt to use the forerunner of the complete theory, the mere notion of a simple periodic arrangement of molecules exerting central forces on one another, had led the eminent mathematicians Cauchy, Navier, Poisson in the 1820–30's to results concerning the elastic behaviour of such solid matter which were not confirmed by experiment, and this failure discredited the entire concept of internal regularity of crystals. Besides, before the invention of the powder diffraction method by Debye and Scherrer and by Hull about 1916 crystals were regarded rather as oddities of Nature than as the typical state of true solid matter of everyday life. In the first few years of X-ray diffraction anyone who was interested in this new method combed the mineralogical collections for suitable crystals having faces of at least 5 × 5 mm. or thereabouts, and it was only in the mid-'twenties that the advantages of using much smaller crystals were found out.

If, then, in 1912 the nature of the solid state was still wide open to speculation, so was the entirely different problem of the nature of X-rays. These rays, discovered in 1895 by W. C. Röntgen in Würzburg, continued to retain much of the mystery that enshrouded them from their first beginnings. Rarely has the discovery of a physicist aroused such a storm of public reaction as that of Röntgen's unknown rays, the X-rays. Röntgen was a character who hated to part with any unfinished experiment by publishing it. He made the chance observation which led him to X-rays on November 8 and, working feverishly in the next six weeks, found nearly all the properties of X-rays that were to be known within the next ten years before he sent his *First Communication* to press on December 28, 1895. The news of these uncanny rays with which you could see the bones in the quick made headlines and gave rise to comments and cartoons in all countries Physicists and medicals alike tried in vain to find out more about the properties of these rays than Rontgen had indicated in his 10-page pamphlet which he sent out to his friends as a New Year's gift

---

* Substance of the first Bragg Lecture delivered at the University of Leeds on June 7 and at the Royal Institution, London, on June 13.

Within a year of Rontgen's discovery three theoreticians gave the same explanation of the nature of X-rays Stokes in Manchester, Liénard in Paris and Wiechert in Konigsberg Their idea was that the electrons, while travelling from the cathode to the anode, form an element of current and are surrounded by a mixed electric and magnetic field On hitting the target they are suddenly brought to rest, and thenceforth produce only an electrostatic field. The sudden transition from one kind of field to the other produces a kink in the lines of force which travels away in all directions like any disturbance caused by the acceleration (or deceleration) of a charge According to this view, the single X-ray is a pulse in the ether similar to the pulse in air caused by a ball of shot landing on its target The emission of the X-ray field could be calculated by Maxwell's equations, and it could be seen that the field would be concentrated on or near to a cone having as axis the direction of deceleration

Among the physicists who carried out calculations along this line of thought was Arnold Sommerfeld, then professor of theoretical physics in the University of Munich He further discussed the faint indications of diffraction which first the Dutch Haga and Wind, and later, in a perfected manner, Walter and Pohl in Hamburg had obtained by using a wedge-shaped, very carefully worked and adjusted slit The intensity profiles on the photographic plates showed not the clear fringe systems obtainable with monochromatic light, but they could be interpreted as the diffraction of a pulse of width of the order of 0 4 Å This order of magnitude was the same as that predicted several years earlier by Willy Wien, who reversed the argument by which Einstein, in one of his four famous papers of 1905, had explained the photoelectric effect In Wien's argument the energy E of an electron falling through the voltage V applied between the cathode and the target of an X-ray tube is given as $E = e\mathrm{V}$, where e is the electron charge This energy is found again in the X-ray photon of frequency $\nu = c/\lambda$, according to the conversion formula between energy and frequency $E = h\nu$, where h is Planck's constant Looking back, Wien's argument was excellent, and we have by now become accustomed to the application of such formulæ in the production of radiation which are not backed by explanatory mechanism, but, at the time we are considering, Maxwell's theory still reigned supreme, and from that point of view these arguments were just black magic which could not be trusted This argument, which predicted an unchecked wave-length from a not understandable formalism, had little effect

On the other hand, there were substantial reasons for doubting the wave-nature of X-rays, and W H Bragg was one of those who felt them most strongly He came to this field, not from the classical Maxwellian theory, but from the study of radioactivity, which he had entered on in 1904, when it was quite a young and most disquieting branch of physics and chemistry Bragg was then professor of physics in the University of Adelaide, and this work was his first research work after seventeen years devoted nearly exclusively to teaching and organizing the University Important results appeared at once from the research The dependence of the ionizing power of α-rays on their velocity, their finite range and the statistical straggling of its length these were results of fundamental importance which quickly made W. H Bragg's name well known He was called to Leeds in 1908, organized there the physics teaching laboratory, and as soon as this was done continued the line of research started in Adelaide The fact that not the intensity but the 'hardness' of γ-rays, measured by their penetrating power, determined the velocity of the secondary β-rays created by them, struck Bragg as a fact of utmost importance In conjunction with H J Porter he investigated whether the same was true for the creation of secondary β-rays by X-rays that is, for the emission of fast photoelectrons by the absorption of X-rays He showed it to be the case, and explained the ionization produced by X-rays to be mainly an indirect one, the energy of the X-ray being used, in the absorption process, for the creation of the fast photoelectron which then, on colliding with the surrounding matter, knocks off further electrons and thereby ionizes the medium

In the primary process, the absorption of the X-ray, a large energy is suddenly transferred to the photoelectron, a fact impossible to understand if the X-ray, like the classical light-wave, conveyed a widely distributed energy flux Such a sudden, localized energy transfer is characteristic of collisions between particles, and therefore was a strong argument for attributing to X-rays a similar nature to that of cathode rays, namely, to consider them as a stream of fast particles. These, however, had to be neutral, since there is no deflexion by electric or magnetic fields This view, which accounted well for all observations implying the photelectric effect and absorption, was put forward by W H Bragg in his book *Studies in Radioactivity*, which appeared early in 1912

Then came, in this very year, Laue's discovery of the diffraction of X-rays, which was conceived out of the opposite assumption, namely, the wave-nature of X-rays It solved the old conundrum of X-rays in a seemingly irrefutable fashion, confirming the wave nature and rejecting the particle assumption The experimental evidence was so strong and simple that it could not be doubted Anyone who has formulated a theory of his own and assembled a large amount of evidence in its favour will appreciate the blow it must have been to Bragg to renounce his theory and to accept the opposing facts Only in one letter to *Nature*, the first of a whole chain of letters by the Braggs, is a statement made which can be interpreted as an attempt to salvage the corpuscular theory, even though this is not mentioned by name It is based on the remark which W L Bragg made to his father during the analysis of the famous diagram of zincblende which formed part of the Laue–Friedrich–Knipping publication, to the effect that all the directions of the secondary X-rays leaving the crystal are 'rational' directions, or 'avenues' between the crystal atoms It is clear that if this were a general property of the Laue diagrams it would lend itself to the interpretation that these 'avenues' are the paths of least resistance to the passage of a stream of corpuscles It was not clear at the time that the statement held only for particular conditions of incidence

Another great physicist, who also came from studies of ionization and was in search of an alternative explanation of the Laue diagrams, Johannes Stark, made a very similar attempt to account for the directions of diffraction by the assumption that 'photons' were channelled in the crystal along the avenues between the atoms or crystal pits (*Kristallschachte*), as he called them.

This letter to *Nature* is dated October 18, 1912. It came at the end of attempts made by W. L. Bragg during the preceding months to test the 'avenue' hypothesis experimentally. They came to nothing, and so were not published; but Sir Lawrence has recently described to me how he went about them. Imagine a crystal slab and a photographic plate fastened to the front and back side of a flat box respectively. The box was tilted in all directions during the exposure, so that X-rays fell on the crystal within a certain solid angle. If they were conducted preferentially along certain avenues of the crystal structure, then, since crystal and plate did not change their relative position during exposure, one would expect strong blackening on the plate where the directions of the avenues intersected it. This experiment was done—like that of Laue–Friedrich–Knipping—with 'white' X-rays, and it showed no effect. Had it been done with a strong monochromatic component in the incident X-ray spectrum W. L. Bragg should have obtained a 'wide-angle' diagram which, though disproving the point it was intended to prove, would have led to an entirely different experimental approach to the whole subject.

There is one last reference which shows that it was not an easy decision for both father and son fully to abandon the particle hypothesis. This is the title of W. L. Bragg's first publication, a paper read to the Cambridge Philosophical Society on November 11, 1912. It is the famous paper in which the spots of the Laue diagrams are explained as reflexions of the incident X-ray beam on the internal atomic planes of the crystal. X-rays are here treated as light waves, full use being made of their destructive interference so characteristic of wave-motion. But, as Sir Lawrence himself notes in 1942 in his address to the first Conference on X-ray Analysis in Industry: "I was careful to call my paper on the structure of zincblende 'The diffraction of short electromagnetic waves by a crystal', because I was still unwilling to relinquish my father's view that the X-rays were particles, I thought they might possibly be particles accompanied by waves".

Although no further mention of the corpuscular theory of X-rays appears in the Bragg publications of the next decades it would certainly be an error to assume that it was entirely eliminated from their minds. Laue, so far as I know, never did any work on ionization and photoelectric processes. He knew of them, of course, but he also knew that all attempts at explaining the photoemission of electrons on classical lines had ended in failure. He could see that right at his doorstep. The photoeffect was one of the major topics of the second Solvay Conference in Brussels in 1913, and Sommerfeld and Debye had prepared a report showing that it would take a resonator a long period of time to accumulate by resonance to an incident spectral line as much energy as is found in the kinetic energy of the ejected electron—whereas no delay in the emission was observed. On the other hand, Laue also knew, of course, of the successful application by Einstein of the quantum relation $h\nu$ = energy to the photoeffect, which, though not giving a satisfactory explanation, rendered the facts. So I presume that Laue was resigned to accepting the corpuscular side of X-rays as one of the many still mysterious quantum phenomena, for the understanding of which the time was not yet ripe. His personal attachment to this side of X-rays was less strong than that of Sir William Bragg.

It is obvious to-day that γ-rays and X-rays presented in the most evident way the general dilemma which later went under the name of particle-wave aspect and gave rise to much fundamental thought, including the principle of indeterminacy of Heisenberg, Bohr's principle of complementarity, and de Broglie–Schrodinger's wave-mechanics.

Such was the expansion of new territory that lay open to investigation along the lines of purely classical optics that even Sir William Bragg did not return to the quantum effects of X-rays. He left the discovery and exploration of Auger effects, Compton effect and atomic and crystalline energy-levels to others.

At the time of Laue's experiment the commercially available medical X-ray tubes usually had a platinum target. Tungsten was only just becoming available, through Langmuir's work, in malleable and workable form, and the Coolidge type fully evacuated X-ray tube, which depended on tungsten, dates only from 1913. Tubes with other targets had to be made to order, and often did not last very long because they could not be sufficiently outgassed. From the work of Barkla in Edinburgh it was known that under the condition of running tubes at rather low voltages there were homogeneous components in the emitted X-radiation, recognizable by the fact that this part of the radiation did not get harder by traversing a number of aluminium sheets, and that its hardness depended only on the target material and not on the applied voltage which affected the remaining part of the emission. There was a definite regular increase discernible in the hardness of these homogeneous components or 'characteristic rays' as the atomic weight of the targets was increased, and this led Barkla to distinguish between a K-series, observed on the lighter targets, and an L-series coming from the heavier ones. Barkla's discovery of the characteristic X-rays together with his second discovery, that of the polarization of X-rays, were the two, and only two, notable advances in the knowledge of X-rays since Rontgen's first nearly exhaustive investigation. It was assumed that the characteristic X-rays were comparable with the line spectra emitted by elements in the optical region, and that the non-characteristic part of the radiation represented the result of the sudden stoppage of the cathode ray electrons on the target, according to the Stokes–Liénard–Wiechert idea. But it must be remembered that the 'kind' of X-rays could at that time be characterized only by measuring the absorption coefficient, and that this means of discrimination had a very low resolving power. The comparison of the characteristic radiation to an optical line spectrum was therefore a conjecture rather than the actual demonstration of the existence of sharp lines.

Laue and Friedrich had planned their experiment so as to obtain a strong secondary radiation. It was known to Friedrich from Barkla's work that the radiation from a commercial tube with platinum target, run in the then usual way with an induction coil and a parallel sparkgap, would excite strongly the K-radiation of elements of atomic weight between 50 and 100. This accounts for Friedrich choosing a copper sulphate crystal in his first attempt, and then ordering the famous zincblende crystal from Steeg and Reuter with which the final photographs were taken that were reproduced in the original publication Laue formulated the theory of diffraction by a three-dimensional grating after the experimental proof of diffraction had been given In applying it to the zincblende diagram, he found that each spot was formed by a definite wave-length λ (or its overtones λ/2, λ/3), different for different spots Since at that time monochromatic X-rays were thought of only in connexion with characteristic radiation, Laue attributed the diffracted rays to a characteristic radiation of the crystal This was not at all in keeping with his own theory, but a misconception which lasted for quite some time, so that when the original publication was reprinted in *Annalen der Physik* this point was reiterated and enlarged on in March 1913 in one of three notes added to the reprinting that is, at a time when W L Bragg had fully explained the pass-filter action of the crystal

Let us, in fact, return to W L Bragg's first paper in the *Proceedings of the Cambridge Philosophical Society*, November 1912 The three important advances made in this paper are

(1) *Reflexion/Diffraction* The spots on the Laue diagram of zincblende are explained as reflexions of the incident beam on internal atomic net planes of the crystal This idea also explains the shapes of the spots—in fact, it was originally deduced from a consideration of these shapes

(2) *Continuous spectrum/Characteristic rays* The appearance of sharply defined wave-lengths in the spots is explained by the selective action of the crystal, which passes only certain wave-lengths out of an incident continuous spectrum

(3) *Face-centred/Simple cubic lattice* It is shown that certain reflexions, the absence of which had already been noted by Laue, should indeed not be observed if the lattice of zinc sulphide was a face-centred cubic lattice instead of the simple cubic one assumed in Laue's discussion

As to the first of these points, W L Bragg states that he sees no contradiction in the reflexion statement to Laue's statement that the spots are caused by diffraction—though his reasons are not elaborated on

Regarding point (2), Bragg assumed the incident radiation to be a 'pulse', that is, not to be of a periodic nature The periodicity in the secondary beam is created by the regularly repeated reflexions of the pulse on the successive net planes This creation of a monochromatic ray has nothing to do with the excitation of characteristic radiation, but it is intimately connected to the topics of the resolving power of a grating and to the concept of coherence of a ray Now Laue had started his career as assistant to Planck, with important papers touching closely on these very topics The notion of the creation of periodicity by the action of a grating should have been alive in his mind I believe it is first to be found in Lord Rayleigh's papers, many of which Laue was familiar with But it was most forcefully explained in Sir Arthur Schuster's *Optics*, a book that was probably unknown to Laue, whose knowledge of English was poor On the other hand, this book formed the base for the teaching of optics in Cambridge by C T R Wilson, and its influence as a background on W L Bragg's argument is patent

The third advance made in Bragg's paper, the determination of the face-centred cubic lattice for zincblende, was a brilliant discovery which could not have been made without the second one For the interpretation of absent reflexions on a diagram taken with a standing crystal presupposes that—within certain limits—all wave-lengths are contained in the incident radiation, that is, that the incident radiation consists of pulses That Bragg was familiar with Pope's arrangements of packing of spheres, including as it does the face-centred cubic lattice, was a help, but without the correct view of the pass-filter action of the lattice it might not have led anywhere It is interesting to note in this connexion that Laue, in one of the three notes added to the reprinting of his original paper (*Ann der Phys*, Leipzig, March 1913), develops the theory of the structure amplitude of a lattice of several atoms, the discussion of which would have given him the correct explanation for the missing reflexions had he not been mesmerized by the idea of "characteristic radiation"

After W L Bragg had presented this brilliant paper to the meeting of the Cambridge Philosophical Society, C T R Wilson suggested in the discussion that since internal crystal planes reflected X-rays, so might external faces do provided they were smooth enough This prompted Bragg to try reflecting the X-rays on a strip of split mica, with the gratifying result of obtaining a reflected image after a very short exposure, and at the expense of a burnt-out platinum contact on the hammer-break of the induction coil This experiment was reported in a letter to *Nature* dated December 8, 1912

It seems justified to regard W L Bragg's paper and the subsequent experimental verification of the reflexion idea as the starting point of a new development leading to the two main fields of application of Laue's discovery X-ray spectroscopy and X-ray crystal analysis In *Nature* of January 23, 1913, W H Bragg reports that the reflected rays which his son registered photographically could also be detected by their ionization This must have been the preliminary experiment on the result of which the construction of the X-ray spectrometer was based· this most powerful instrument with which practically all progress was achieved in 1913 and 1914 and the early post-War years It was an instrument which could be constructed rapidly by transforming an optical spectroscope, and its efficiency was due to the well-placed system of slits at the tube and at the entrance to the ionization chamber, to the sensitive ionization chamber, and the avoidance of variations of capacity by placing the electrometer by means of which the ionization current was measured under the axle of the spectrometer about which the chamber was being turned It embodies much of the experience W H Bragg had gained in the course of his previous work on ionization by α and other rays

The spectrometer revealed for the first time the correctness of the assumption that the radiation coming from the tube contains a mixture of 'white' X-rays or Bremsstrahlung pulses and of nearly monochromatic radiation The resolving power of the slit system was not at first good enough to separate sharply the spectral lines—but this was, perhaps, very fortunate, for Moseley and Darwin, who had started similar work independently and only a little later in Manchester, using fine slits, missed the characteristic lines altogether before they knew from Bragg's work where to look for them

While W H Bragg perfected the spectrometer, his son in Cambridge succeeded in making the first structure determinations by comparing the Laue photographs of various alkali halides These first structure determinations were of fundamental importance. They solved the mystery of what was the nature of the primary particles assumed but not defined in the structure theories. They laid down the absolute scale in which atomic distances and X-ray wave-lengths could be measured. They used, as a criterion of the correctness of the assessment of atomic sites, the idea of the completeness of the diagram, that is, the notion that, within certain limitation of angular and spectral range, the diffracted spots that could be expected were actually there, no more and no less.

Using this rock-salt structure and the reflexion angles measured on the spectrometer, W. H. Bragg determined the absolute values of the wave-lengths of the L-radiations of platinum, nickel and tungsten. He had to show that the peaks found on the spectrometer were indeed those of characteristic radiation. By measuring the absorption coefficient he identified the radiation according to Barkla as either K-radiation from an element of atomic weight 74, or L-radiation from atoms of weight 198. The latter is in good agreement with the platinum target (at. wt., 195). Again, according to Whiddington, the production of rays of the measured absorption coefficient requires electrons of a certain minimum energy, and this value fell close enough to that obtained from the wave-length by means of the equivalence $E = h\nu$. It is interesting to note this roundabout argument, the only one then available; its importance lies in the fact that by confirming the absolute value of the wave-length obtained via the sodium chloride structure, this structure itself, which was derived only with the help of λ/a ratios, was also confirmed. It thus became certain that the nodal points of the structure really carried atoms, and not sodium chloride molecules as might have been expected.

The further development of the work of Sir William Bragg and his son is better known than these quite early stages, and I need mention only a few points which appear to me to be of particular importance.

(1) The exploration of X-ray spectroscopy, although begun by W. H. Bragg, was soon taken over systematically by Moseley in Manchester and Oxford and Maurice de Broglie in Paris. Both found the photographic registration of spectra more convenient and more accurate for angular measurement than the ionization method. This work was of the greatest importance for the then developing atomic theory.

(2) The determination of the structure of diamond in 1913 was an important step forward because of the simplicity and beauty of the structure, and because it was the first structure which found the undivided approval of physicists as well as chemists. Prof. Bragg was to report on this structure at the Birmingham meeting of the British Association for the Advancement of Science of that year, and I had seen the announcement of the talk in *Nature* (I was then living in Munich and a few months married). The announcement prompted me to throw overboard all plans for a honeymoon on the Bay of Biscay and to follow the inner call to Birmingham. Neither my wife nor I has ever regretted this, for it was a fine meeting, with Lord and Lady Rayleigh receiving the guests at the reception and Oliver Lodge delivering the presidential address, and Marie Curie, the "silent woman, rushing off to France", as the disappointed reporters put it, getting an honorary degree. Bragg's talk, with the wonderful result and the beautiful directness and simplicity of the argument, made a deep impression on all. After the talk, a crowd of colleagues and friends gathered round the speaker congratulating him and asking questions. When they were gone I approached him—quite unknown to him and a young man who might have been his son—and after a few words of admiration told him that I disagreed with his calling the first reflexion observed on the octahedral face a first-order spectrum while also calling the first observed reflexion on the cube face a second-order spectrum. The latter should be considered as a fourth-order if referred to the same cubic axes. I am telling this because I think that Sir William's reaction was that characteristic of a truly great and liberal mind. Instead of being convinced of his better understanding, or being annoyed, he thought for a few seconds and simply said "Yes, you may be right. I see your point".

(3) In the third instance I would like to mention the 'normal intensity sequence' in the successive orders of reflexion obtained from a set of equal equidistant net planes. The theory of intensities was not well developed until well into the late 1920's, when W. L. Bragg and his co-workers in Manchester advanced it to a useful stage. On the other hand, as soon as any information is needed on the mutual arrangement of atoms in the basic cell of the crystal this can only be obtained by a discussion of the intensities of the reflected rays. It would have held up crystal structure analysis for 10–15 years if one had wanted to wait for an applicable theory of intensities—which in fact remains even to-day one of the major problems. W. H. Bragg circumvented this difficulty by introducing a normal intensity sequence of 100 : 20 : 7 : 3 : 1. Where this was not observed, it was an indication of unequal distances and unequal atomic populations of planes within the set of parallel planes of atoms. This approximate rule, gathered from the great wealth of measurements made, was most helpful for overcoming the formidable difficulties in interpreting the measurements in terms of structure.

Although W. H. Bragg started out as a mathematician—he was third wrangler in the Mathematical Tripos Part I in 1884 and prepared himself for his double role of professor of mathematics and physics in Adelaide only on his way out in 1886 by reading up on electricity and magnetism—he became fully convinced of the strength of simple reasoning in physical terms, and for his own use discarded as much as possible mathematical formalism. His determinations of crystal structures like those of diamond, quartz, or anthracene–naphthalene are based on the simplest of geometrical arguments, and this makes the reading of these papers or of their condensation in the classic volume *X-rays and Crystal Structure* so instructive and delightful. The method of deduction followed there trains the reader to geometrical perception in three dimensions, an aptitude that can be greatly improved by practice and which both Sir William and Sir Lawrence possessed or developed to a remarkable degree. It makes the results appear to be gained in a nearly effortless way, and when one listened to Sir William lecturing on his work he seemed to live through the joy of discovery and of the clinching argument every time afresh. He was, and will remain, one of the great masters of scientific exposition, and this art he may well have acquired during his first, non-productive period at the University of Adelaide.

This direct approach also explains Sir William's attitude towards the formal theory of space groups. As a trained mathematician he might have seen its general importance, but as one converted to direct physical argument he had no use for this formalism. Shoji Nishikawa, who was one of the earliest to appreciate the help to be obtained from space-group theory, on visiting Sir William in 1919, handed him a paper he had written on this subject asking him to publish it if he thought it was meaningful—but it never again saw the light of day. About 1923 Bernal had worked through space-group theory on his own—but this attempt was not encouraged. When, not much later, Astbury and Yardley had worked out their space-group tables it took "some persuasion" to obtain Sir William's backing for the publication.

In his Bakerian Lecture of 1915 Sir William spoke in very clear terms of the connexion between Fourier analysis and diffraction effects. But this remark lay dormant for more than ten years, and the present application of Fourier methods in all parts of diffraction theory sprang from Duane and Havighurst's work in the United States rather than from Bragg's Bakerian Lecture. Again I believe it was too formal an approach to fit into the simple line of thought Sir William meant to cultivate.

Sir William was, as his son is now, fully aware of the responsibility of leadership in scientific thought implied in his position as director of the Royal Institution. He felt strongly the honour and the obligation of working at the little mahogany desk which Faraday had used. Over his many and responsible duties as officer of the Royal Society, the International Union of Pure and Applied Physics and of a large number of special committees, he did not neglect the traditional duties towards the coming generation. His Christmas Lectures on "The World of Sound", "Old Trades and New Knowledge", "The Universe of Light", are wonderfully suited to arouse the interest of children or adolescents in science. I vividly remember the beautifully simple and impressive lecture Sir William gave in 1931 on the occasion of the centenary of Faraday's discovery of electromagnetic induction in the lecture room of the Royal Institution where Faraday himself so often lectured, and with Faraday's original coils and instruments for the demonstrations. I remember, too, the loving pains he gave to the edition of Faraday's diaries with all their little interspersed drawings, and how pleased he was to see this greatest treasure of the Royal Institution safely published. Sir William knew well what he owed to those who worked before him, and he served them in filial piety. It is up to us to render the same service to him, the great man, friend and teacher whose work opened the way for us.

TIME-RESOLVED INTERFEROMETRY OF RUBY LASER EMISSION

By T. P. HUGHES

Research Laboratory, Associated Electrical Industries, Ltd., Aldermaston Court, Aldermaston

IN connexion with the possible use of the ruby laser as a light source in plasma diagnostics[1], and in order to elucidate further the mechanism of laser action, it is necessary to know how the spectrum of the laser emission varies in time. The time-integrated spectrum has been examined by a number of workers[2-5]. This article describes what are believed to be the first observations of the time-resolved spectrum, obtained with a Fabry–Perot interferometer and a rotating mirror camera, and proposes a new explanation of the 'spikes' of laser light intensity.

A cylindrical pink ruby crystal, 5 cm long and 0·6 cm in diameter, cut with its crystal axis at 90° to the axis of the cylinder, was used in the experiments. Its ends, flat to $\lambda/10$ and parallel to 6 sec of arc, were coated with dielectric multi-layer reflectors, one being almost opaque and the other transmitting a few per cent at 6943 Å. The crystal was mounted inside an Associated Electrical Industries helical xenon flash tube (type *FA*26), energized by a condenser bank of capacity 1,200 μF charged to 2·5 kV. Under these conditions, which were kept constant throughout the experiments, laser action began about 400 μsec after the flash tube was triggered and lasted for about 1·4 msec, so the pumping energy was well above the laser threshold. The flash tube and ruby crystal were cooled by a rapid flow of air at room temperature.

The optical arrangements used for most of the work are shown in Fig. 1. The front surface of the laser crystal was 44 cm from the fore slit S_1. In the absence of the etalon E the rotating mirror camera swept an enlarged image of a narrow strip of the laser emission pattern across the photographic plate P. When the etalon was in place, the fringe pattern it produced was focused by the lens L_2 on to the slit S_2, with the vertical diameter of the pattern coincident with the slit centre. Each etalon place had a small wedge angle, disposed so that with the aid of S_1 and the lens L_1 both the principal ghost images were rejected by S_2. The etalon could be set up with the plates separated by 1·00, 3·16 or 10·15 mm, for which the changes in wave-length required to displace a fringe by one order are 2·4, 0·76 and 0·237 Å respectively in the region of 6943 Å.

Each pulse of laser emission consisted of a large number of the well-known 'spikes' of intense light. By rotating the mirror at a speed sufficient to resolve these in time, a series of snapshots of that part of the laser pattern which entered the slit S_1 was produced. The sweep speed required to do this made it impossible to record the whole duration of the laser emission, but with appropriate synchronization any part of it could be examined at will.

By removing S_2, replacing S_1 by a small circular aperture, reversing the order of the telescope lenses

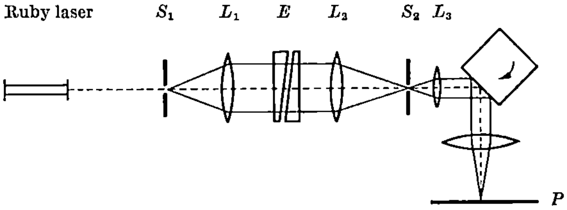

Fig. 1. Optical arrangements

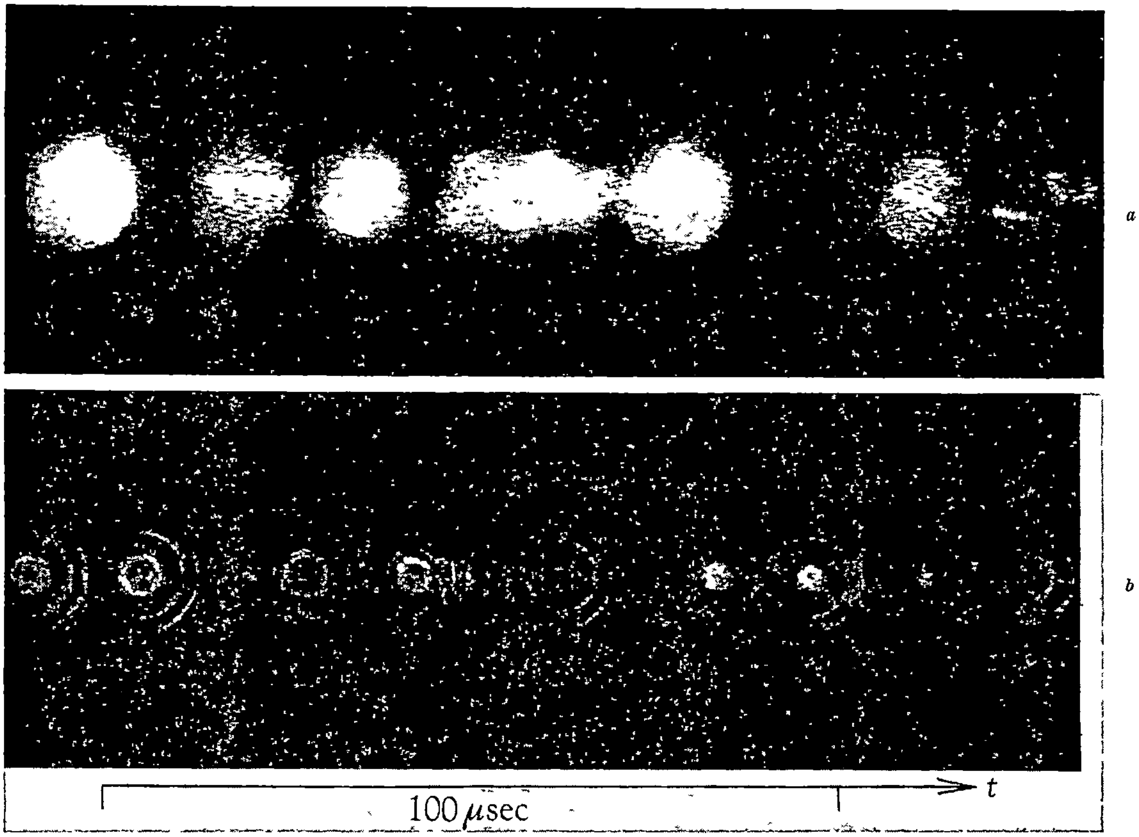

Fig. 2. Streak photographs of whole field, towards end of laser pulse. *a*, without etalon; *b*, with 3.16-mm etalon

L_2 and L_3 and moving the laser closer to the camera, a small image of almost the whole field of the laser emission could be recorded for a sequence of spikes. At a suitable mirror speed it then became possible, towards the end of the laser pulse when the spikes were well separated in time, to record the complete patterns due to successive spikes in considerable detail, often entirely without overlap. An exposure made in this way without the etalon is shown in Fig. 2*a*. It may be seen that, in agreement with the observations of Borie, Durand and Orszag[6] using a framing film camera and of Clark, Wuerker and York[7] using an image convertor camera, elements distributed over the whole of the far field contribute simultaneously to a spike, and the intensity pattern changes (often drastically) from one spike to the next. The very sharp images obtained from most spikes show that in general their duration is less than 0.3 μsec, but some of the patterns appear to persist for 2 μsec or longer. Fig. 2*b* was obtained similarly to Fig. 2*a*, but with the 3.16-mm etalon in position. The wave-length distribution of the emission appears to be the same over the whole pattern in a spike but varies considerably between spikes.

Fig. 3*a* is a streak photograph obtained using the optical arrangements of Fig. 1 without the etalon. The mirror was rotating sufficiently slowly for the whole laser pulse to be recorded; only a few spikes are resolved. Figs. 3*b* and *c* were obtained in that order from successive pulses separated by about 1 min, under the same conditions as Fig. 3*a* but with the 3.16-mm etalon in place. The mean radii of the fringes decreased by about half an order during each pulse, corresponding to an increase in the mean laser wave-length of about 0.4 Å. Taking the value quoted by Maiman[8] for the rate of change of the R_1 line wave-length with temperature (about 0.05 Å °C^{-1} at room temperature) this effect can be explained by a rise in the crystal temperature of about 8° C (observations quoted by Pringsheim[9] indicate that the wave-length increases as the temperature rises). The flash tube emission persists for some msec after the laser action ends, so a further rise in temperature must occur. Only part of the energy absorbed by the crystal will be dissipated in 1 min, so in the next pulse the crystal will be somewhat warmer at each stage and the fringe radii correspondingly smaller, as is observed.

The photographs shown in Figs. 4*a*, *b* and *c* were taken at eight times the speed used for Fig. 3, and only the first part of the laser pulse was recorded. From the streak photograph taken without the etalon (Fig. 4*a*) it may be seen that at the beginning of the laser action only the central region of the field is illuminated. Fig. 4*b* was taken under the same conditions as Fig. 4*a*, but with the 3.16-mm etalon in position. The variations in output wave-length are confined to a range ± 0.4 Å about the mean. This was confirmed by observations with a 1-mm etalon. With a 10.15-mm etalon Fig. 4*c* was obtained, which reveals the nature of the laser light in more detail. The wave-length distribution in a single spike consists of one, or a few, highly monochromatic components. The half-intensity breadth of each component must be $\leqslant$ 0.03 Å. However, the central wave-lengths of the components vary considerably between spikes, and these variations show remarkable regularities. The magnitudes of the wave-length

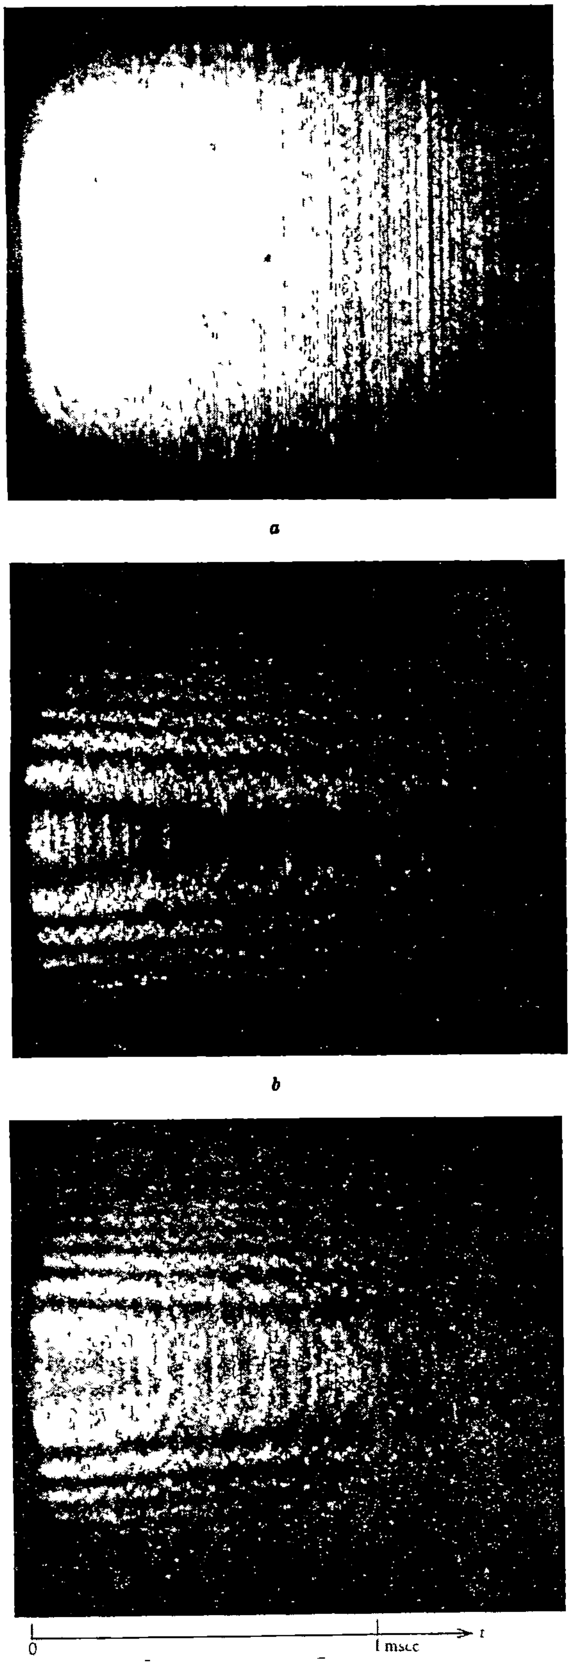

Fig 3 Slow streak photographs of complete laser pulses *a*, without etalon, *b*, *c*, with 3 16-mm etalon two successive pulses

steps very often appear to be 0·025 or 0·05 Å, which are approximately those required to change by one or two the number of wave-lengths in twice the optical length of the ruby crystal. This result is in agreement with the observations of Abella and Townes[4] and of Ciftan *et al.*[5], who deduced from their time-integrated interferograms and spectrograms that the laser resonates in the longitudinal mode at a number of eigenwave-lengths λ near the R_1 line centre, such that $n\lambda = 2D$, where D is the optical length of the crystal, and n is one of a series of adjacent integers. Under the conditions of the present experiment n takes about 30 values in the neighbourhood of 2.5×10^5.

In general, only one or two eigenwave-lengths are excited in any one spike, though occasionally a few more are present. The same eigenwave-length very rarely appears to occur in consecutive spikes. At the beginning of the laser pulse there is a steady step-wise progression towards longer wave-lengths which is reproduced in all exposures obtained under these conditions. If the interpretation given above of Figs. 3*b* and *c* is correct this effect cannot be explained by thermal changes, which are an order of magnitude too slow.

These results suggest the following explanation of the mechanism of spike emission. Although the natural lifetime of the excited state giving rise to the R_1 line is long, the R_1 line profile of the crystal as a whole is broad because different Cr^{+++} ions are subject to different perturbations. This broad profile may be divided into small elements surrounding each eigenwave-length of the laser. Then the condition for laser action to occur at one of these eigenwave-lengths, say λ_i, is that sufficient population inversion has been achieved between the excited state and the ground state in that group of ions for which the R_1 transition lies very close to λ_i. It follows that in the first spike of laser emission only those λ_i's closest to the centre of the R_1 line profile will be present, and only a fraction of the total population of excited ions will be de-excited. The next spike will occur a little later, when those ions associated with eigenwave-lengths slightly lower down the R_1 line profile have been pumped sufficiently, and so on. Supposing the R_1 line profile to be Gaussian for simplicity, with a half-intensity breadth of 2 Å, and neglecting losses, it may be shown that if at constant pumping power the first spike occurs after pumping for t sec, then the twenty most central eigenwave-lengths (with intervals of 0·025 Å) will be emitted within the next $t/30$ sec. Losses will make laser action impossible outside a certain wave-length range, which will be broader at higher pumping powers. However, before these distant eigenwave-lengths have been reached others nearer the R_1 line centre will be active again as a result of further pumping and of relaxation processes. It should be noted that, unless the R_1 line profile is asymmetrical, this model does not explain why early spikes progress towards longer wave-lengths preferentially.

Similar considerations presumably apply to other laser materials and geometries.

By cooling the crystal, and thereby narrowing the fluorescent line profile, the number of eigenwave-lengths and their overall spread will be reduced but their separation will be unchanged. Also, the separation of adjacent eigenwave-lengths is inversely proportional to the length of the crystal. Thus a short cool crystal may possibly operate in a single longitudinal mode, even well above the threshold pumping power. Further experiments designed to test these ideas are in preparation.

I thank Dr. J. Dyson and Dr. A. A. Ware of this Laboratory, and Dr. R. Dunsmuir of the Associated Electrical Industries (Rugby) Research Laboratory, for helpful discussions, and Mr. R. P. de Ste. Croix for assistance with the experiments. I also thank Dr. T. E. Allibone, director of this Laboratory, for permission to publish this article.

OBITUARIES

Sir John Felton, O.B.E.

SIR JOHN ROBINSON FELTON died at Sutton, Surrey, on June 21 in his eighty-third year. He was sixty-seven when he retired in 1947 after having been for five years H.M. Chief Inspector of Mines and Quarries in the Ministry of Fuel and Power, now the Ministry of Power.

The son of George and Isabella Felton, he was born at Blyth, Northumberland, on February 28, 1880, and educated at Gateshead Higher Grade School, then at Armstrong (now King's) College, Newcastle upon Tyne.

His mining engineering apprenticeship was served at West Stanley Colliery, Stanley, Co. Durham, and Stobswood Colliery, Northumberland. After obtaining his Home Office certificate of qualification he was appointed manager of West Stanley Colliery in 1903. He left in 1908 to begin what was to prove a long and distinguished career in H.M. Inspectorate of Mines and Quarries, then under the Home Office.

Felton served in the South Staffordshire Mines Inspection District for fifteen years until 1923, the first seven as an assistant inspector and eight after being promoted to senior inspector. For a period in 1920–21 he was deputy director of production under the Coal Controller. He was appointed an officer of the Order of the British Empire in 1920.

In 1923 he was transferred as senior inspector to the Yorkshire and North Midland Division. This mines inspection division was split the following year and he was promoted to be the first divisional inspector of the newly formed East Midland Division.

He was promoted to H.M. Deputy Chief Inspector at London Headquarters in 1937, then appointed Chief Inspector in 1942. Knighted in 1946, he retired in 1947. For some time after his retirement he was a member of one of the Valuation Boards under the Coal Industry Nationalization Act.

Felton was an honorary member of the Midland Counties Institute of Mining Engineers. He had been president during 1936–37 and adopted as the subject of his presidential address the "Safety and Health of Mineworkers". He further contributed to the *Transactions of the Institution of Mining Engineers* "Some Notes on a Visit to Germany" and was the author of five special reports on colliery disasters at Bilsthorpe (1934), Markham (1937), Barnsley Main (1942), Manvers Main (1945), and Harrington (or Lowca) in 1947.

His recreations were reading and almost certainly writing, for his penmanship was outstandingly good. He had a deep love of music and of church music in particular. He was organist and choirmaster at Methodist churches at West Stanley and elsewhere, for as he moved about the country he remained until the end a devout and active church member.

Sir John was a man of wide and deep sympathies, greatly interested in the welfare of young people and for many years associated with the National Children's Homes. He was also very much concerned with the welfare of old people and took a leading part in the provision of houses for them in the Sutton district.

His wife died in 1936 and his only child, a daughter, in 1953. In recent years he had been greatly troubled by failing eyesight, but he bore all his misfortunes with fortitude and invariable cheerfulness.

T. A. Rogers

Prof. A. J. Grove

Alfred John Grove, professor emeritus in the University of London, who died on June 5 at the age of seventy-four, held from 1947 until his retirement the newly created chair of zoology at Queen Mary College. Indeed, this appointment was largely a tribute to his work in building up the Department from small beginnings during the years 1929 and onwards.

Grove took his first degree at Birmingham when he was only nineteen and was at once awarded a scholarship to work on entomological problems. A series of papers, mainly on the functional morphology of insect mouth parts, was recognized by the award of the D.Sc. degree of that University, and soon by the grant of an 1851 Exhibition which took him to Cambridge in 1910, where he continued his studies for a year as a member of Emmanuel College. From 1911 until soon after the outbreak of the First World War, Grove was employed as an entomologist in the Indian agricultural service, but he was then drawn back into university life as a lecturer at his old University. When it became apparent that there was a need for medical entomologists, Grove volunteered for service in the Royal Army Medical Corps and worked with teams controlling malaria in the Middle East, particularly in Palestine. He resumed his interrupted academic career by accepting a lectureship in the University of Sheffield shortly after the War ended and stayed there until 1929, when he joined G. P. Mudge in the small department at East London College (as Queen Mary College was then called). Up to that time the department had been solely concerned with preparing students for first medical examinations, but now it began to accept students for general and special degrees in zoology. Re-equipment and expansion were inevitable and in 1936 the department moved, with Grove as its head (Mudge having retired), into new quarters in the newly built west block, where it is still housed.

The Second World War put a brake on further material progress, for in 1939 a greatly diminished Queen Mary College was moved to Cambridge for the duration of the War, but there can be no doubt that the war years spent in the stimulating atmosphere of Sir James Gray's Department was of lasting benefit to Grove and his colleagues; it is a pleasure to place on record that this is still remembered with gratitude. The happy relations between the two Zoology Departments was in no small measure due to Grove's eagerness to co-operate and to take full advantage of the splendid resources put at his disposal.

Grove will be remembered by his colleagues as an authority on the reproduction of earthworms as well as for his contributions to insect morphology, while many generations of students are grateful for his text-books and laboratory manuals which bear witness to his ability as a meticulous teacher. Grove took a full share in examining for the University of London and never shirked any of the onerous and time-consuming administrative duties inevitable in a large university either within the College or at the Senate House and by the time he retired he had been a dean for many years and chairman of several important committees, posts which he filled with great success.

G. E. Newell

Prof. Franciszek Adamanis

Polish pharmacy suffered a great loss when Prof. Franciszek Adamanis, professor of pharmaceutical chemistry at the Medical Academy in Poznan, died of cancer on April 14. His intellectual qualities, combined with his open-hearted friendliness, earned him the respect and affection of many pharmacists abroad as well as in Poland. His own interests and affections were deeply connected with the profession of pharmacy. He was a champion of the improvement of the status of this profession, in opening the door for a pharmacist to the analytical and biochemical laboratories and to the pharmaceutical industry. The aim of his life was to gain recognition for pharmacists in the fields of analytical chemistry, biochemistry and microbiology.

Franciszek Adamanis was born in Libawa (Latvia) on October 4, 1900. He finished his secondary education in Homl (Russia) in 1918 and entered the Faculty of Law in the University of Poznan. Later, he became a member of the Faculty of Pharmacy, and in 1927 he gained his Master's degree for work on Heinz Aldol. For his first scientific work he was awarded the bronze medal by the Senate of the University.

In the same year he started to work as an analytical chemist in the chemical industry and in 1929 he became a director of the firm Akwawit in Poznań. In 1930 he started to work on his Ph.D. thesis under the guidance of Prof. Konstanty Hrynakowski. He studied the additive combinations of the molecular compounds of urea by the method of thermal and optical analysis. He determined the forces of co-ordination existing between components of the molecular compounds and the effect of these forces on the biological action. He also pointed out the relation between the additive properties of tri-valent nitrogen and its pharmacological action. The very promising results of his research made possible his graduation for Ph.D. in 1932 and his habilitation for docent in 1937.

After the death of Prof. Hrynakowski in 1938, he became the head of the Department of Pharmaceutical Chemistry at the University of Poznan

After the outbreak of the Second World War he was taken prisoner and sent to the concentration camp in Gusen, Austria, from 1940 until 1945 The deep honesty of his character helped him to maintain an inflexible position In trying to save the lives of many people, he organized the production of drugs in the simple and primitive conditions of the camp's laboratory He distributed more than 40,000 ampoules of injections among people, running the risk of losing his own life every day.

After the War he returned to Poland and started to rebuild from the ruins of the University of Poznań the Department of Pharmaceutical Chemistry His post-war scientific work extended into two main efforts First, he pioneered the teaching of pharmaceutical chemistry and the change of the old traditional programme which was based on the division of drugs according to their chemical structure In his book *Chemia Lekow*, which appeared in three editions, he presented a modern approach in chemistry of drugs, giving their division from the pharmacological point of view The post-war research mainly concerned the adaptation of modern analytical methods, for example, chromatography to the analysis of active substances of plants, especially alkaloids and glycosides Another line of research which resulted from his analytical school was that on the stability of drugs, which will be continued by his disciples He was the author of 75 original research papers and several theoretical reviews He guided Ph D theses for 19 pharmacists

In 1946 Adamanis was nominated professor of pharmaceutical chemistry, and in 1958 he became full professor In addition, he was director of the State Institute of Medicinal Plants in Poznań until 1954, and dean of the Faculty of Pharmacy during the academic year 1951–52, for the past four years he was pro-rector of the Medical Academy in Poznan He took part in several international conventions of pharmacists and worked as an active member of scientific and pharmaceutical organizations He was a member of the Committee of Pharmaceutical Sciences at the Polish Academy of Science, president of the Section of Pharmacy at the Poznan Society of Friends of Science, president of the Polish Pharmaceutical Association from 1960, member of the Polish Pharmacopœia Commission, vice-president of the Section of Medicine at the Main Council of the Ministry of Education, and member of the American Pharmaceutical Association In addition to this, he took part in work of social organizations His great endeavours were rewarded by the City of Poznan and by the Government

Adamanis was a man with an unusual background who had a variety of interests his knowledge of Russian literature was exceptional, and he was an expert in architecture and sacral art His main 'hobby' was photography, and he was also a strong supporter of the cultural background of his students Now death has taken this great man, whose deep honour and honesty will remain the ideal for all future pharmacists

DANUTA MALEJKA

NEWS and VIEWS

California Institute of Technology

ON June 30, four distinguished scientists retired from their chairs in the California Institute of Technology, each having reached the full retiring age of seventy the honour of professor emeritus has been awarded to them

Prof A H Sturtevant

PROF A H STURTEVANT was Thomas Hunt professor of genetics He has been at the Institute since 1928. He was a member of Morgan's original '*Drosophila* group' that pioneered the new science of genetics, largely through the study of the *Drosophila* fruit fly. Among many major contributions, Prof Sturtevant demonstrated that the genes lie in linear order and he helped to develop chromosome theory Prof Sturtevant is the author or co-author of 137 scientific publications, including several books Among the books are *An Introduction to Genetics*, written with Dr George W Beadle, formerly of the Institute and now president of the University of Chicago, and *Genetics and Evolution*, a collection of Prof Sturtevant's scientific papers selected by Dr E B Lewis, professor of biology in the Institute

Prof C. C Lauritsen

PROF C C LAURITSEN was professor of physics, and pioneer in nuclear physics and rocket research He has been on the faculty of the Institute since 1929 He was one of the pioneers in research in the field of nuclear physics, and under his leadership the Kellogg Radiation Laboratory has, for three decades, been one of the world's leading centres of nuclear studies Prof Lauritsen was also scientific director of the very large and active rocket-development group at the Institute during the Second World War, and in subsequent years became one of the leading advisers to the Government on military and scientific matters He received the Medal of Merit for his war work In addition to serving as technical consultant to the Army, Navy and Air Force on nuclear weapons and rockets, he spent a year at Los Alamos as special consultant on the atomic bomb project He also helped formulate plans which led to the establishment of the Office of Naval Research

Prof E C. Watson

PROF EARNEST C WATSON, professor of physics, was formerly dean of the faculty, and one of the builders of the California Institute of Technology Since 1960 he has been on leave as scientific attaché to the U S Embassy in India He supervised the planning and development of the well-known Norman Bridge Physics Laboratory at the Institute His wife, Jane Werner Watson, is the author of nearly two hundred children's books

Prof F J Converse

PROF F J CONVERSE is an authority on soil mechanics He is president of the Converse Foundation Engineering Co and has been consulted as a foundation engineer in the construction of many dams, tunnels, factories, military installations, shipyards, airports, power plants and sub-stations throughout the United States, and has done such specialized jobs as investigating the ground settling at Terminal Island

Explosives Research and Development Establishment, Waltham Abbey

Dr. G H S Young

Dr G H S Young, of the Ministry of Aviation's Explosives Research and Development Establishment, Waltham Abbey, has been promoted to deputy chief scientific officer and given general charge of all development work and chemical engineering in the Establishment After graduating from the Honours School of Chemistry at the Imperial College of Science and Technology, London, in 1937, he took the diploma in chemical technology in 1938 and continued thereafter his research under the late Sir Alfred Egerton on the slow combustion of hydrocarbons which gained him a Ph D in 1939 At the outbreak of war, Young was drawn into technical work for the Services, initially at Imperial College and later at Woolwich and Swansea During 1941–45 he was attached to the Proof and Experimental Establishment at Inchterf in Dumbartonshire, where he learned the hard way about practical matters connected with the performance of cordite in guns, and concurrently about the related problems of propellent manufacture at the nearby Ordnance Factories

Young became a foundation member of the staff at Waltham Abbey when the Research and Development Establishment was set up there in 1945 by the Ministry of Supply From then onwards until 1953 he was in L A Wiseman's group studying the combustion of liquids and gases In particular, he made some of the earliest measurements in Great Britain of the attenuation and modulation of micro-wave signals by rocket exhausts, and looked into the controlling factors During this period Young served as secretary of the Spectrochemical Committee of the Scientific Advisory Council In 1953 he was promoted to superintendent rank, and although this necessitated a switch into predominantly development work he has nevertheless found time to build up the team responsible for rheological research on solid propellents and broaden its scientific basis

Botany in Kashmir

Dr T N. Khoshoo

Dr T N Khoshoo, who has recently been appointed head of the Department of Botany at the University of Jammu and Kashmir, was born on April 7, 1927, at Srinagar, Kashmir, He gained an M Sc (Hons) in botany at the Panjab University, Lahore, in 1946 and was the recipient of several prizes, including the "Prince of Wales Gold Medal" for high performance in biology in general and botany in particular Soon after the partition of India, he joined the Panjab University, Chandigarh, where he gained his doctorate and became a senior lecturer In May 1962 he joined the University of Jammu and Kashmir as reader and head of its Postgraduate Department of Botany Dr Khoshoo has been actively engaged in working on the cytology of gymnosperms and the experimental evolution of some polytypic angiosperms of north-western India On these topics he has published about fifty-five research papers, including his work on polyploidy in gymnosperms, cytogenetical evolution in gymnosperms, the karyotype in *Welwitschia mirabilis*, etc Of special interest are his investigations of the *Sisymbrium irio* complex, which is still being continued by him Several other plant species have now been included in this project With his wide experience in field botany of the north-western Himalayas, it is hoped that he will be able to enlarge these investigations and soon build up an active school in experimental evolution and ecogeography of the plants of the Kashmir region Dr Khoshoo is a Fellow of the Indian Academy of Sciences, Bangalore, and joint editor of *Silvae Genetica Journal of the Forest Genetics and Forest Tree Breeding*, published from Schmalenbeck

Government Support for the British Academy

In a written answer in the House of Lords on July 10, the Minister for Science, Lord Hailsham, said that in the light of discussions between the British Academy, and the Government, and at the suggestion of the Government, the British Academy prepared an outline scheme under which the Academy itself would administer an additional grant for the support of research in the humanities The scheme excludes the social sciences which present a different problem involving a wider field of Government interest The Government proposed an additional grant of £25,000 to the British Academy in 1963–65 for this scheme, and it was envisaged that in two or three years the figure might rise to a steady level of £50,000 a year Any extra administrative costs incurred by the Academy in administering the scheme would be found out of the grant The British Academy warmly welcomed an arrangement on these lines and the Government appreciated the efforts of the Academy both in presenting the problem constructively to them and in devising the scheme

Grant for University of London Nuclear Reactor

In a debate on science and technology in the House of Commons on July 12 it was announced that a grant of about £250,000 is being offered to the University of London by the Department of Scientific and Industrial Research to provide a low-power nuclear reactor for research and training The reactor, a 100-kW *Consort* made by the General Electric Co , Ltd , will be operated by Imperial College on behalf of the University and will be built at Imperial College's Field Station at Silwood Park, near Virginia Water, Surrey While intended primarily for the University of London, it will be available for use by other research organizations in the London area In May 1961, the Government announced that it had agreed in principle to the award of three grants for low-energy nuclear reactors for British universities one to the four Scottish Universities and the Royal College of Science and Technology, Glasgow, jointly, one to the University of London , and one to the Universities of Liverpool and Manchester jointly Final approval of these projects had to be postponed in July because "the scientific expansion in all fields seemed likely to exceed planned financial resources" In December the Council was able to go forward with one of these awards—£450,000 to the Scottish Universities Work on this project is going forward to schedule, and the Scottish consortium has been joined by the Queen's University of Belfast At that time the Department of Scientific and Industrial Research stated that it hoped to make an announcement later about the remaining two projects

Research Group in Epigenetics at Edinburgh

The Medical Research Council has recently agreed to the formation at the University of Edinburgh of a Research Group in Epigenetics The Group is to be under the direction of Prof C H Waddington, and will be attached to the Department of Animal Genetics It is expected that the support will be made available by the Research Council for a period of at least ten years, the total sum involved over this period being of the order of £200,000 The Wellcome Trust have provided a capital sum, up to £50,000, to make possible the erection of a new laboratory to house the work The field of the Research Group covers all those processes by which a newly fertilized egg develops into the differentiated cells of the adult organism As medical science finds ever more powerful methods for the control of infectious disease and the repair of accidental damage, disorders of developmental processes are bound to acquire increasing importance among the medical problems of the future If such degenerative diseases as rheumatism, arthritis and senescence in general, disorders of growth (as in cancer) and the developmental mishaps which produce congenital abnormalities are to be dealt with satisfactorily a much more profound understanding will be required of the processes by which the simple cells of the embryo acquire, and maintain, the specific characters of the different tissues of the adult animal In the past few years, several particular problems within this general field have been under investigation at the Edinburgh Institute of Animal Genetics, both by members of the University staff and by workers financed by the Nuffield Foundation, the British Empire Cancer Campaign, the Agricultural Research Council and the Damon Runyon Trust for Cancer of New York The resources now provided by the Medical Research Council will make it possible to build up a group of workers who can bring to bear most of the numerous modern relevant techniques in an organized attack on the very complex problems of fundamental biology which underlie the many diverse manifestations of developmental disorder with which mankind is afflicted

The Forestry Commission

The forty-second annual report of the Forestry Commission for the year ended September 30, 1961, provides not only an account of the Commission's work but also shows the progress in both State and private forestry (Pp 70+8 plates London H M S O, 1962 5*s* 6*d* net) At the same time, there is the disturbing note that although 100,000 acres were planted with trees during 1960–61 (64 per cent by the Commission), insufficient land was acquired by the Commission to support the planting programme adopted in 1958 There is still a certain reserve of land suitable for planting, but with this reserve diminishing instead of being maintained until nearer the end of the planting programme it may cause some difficulties with planning nursery work where provision for plants must be made perhaps some four years before they are required The Forestry Commission's effective estate, including land to be planted, was 1,671,081 acres on September 30, 1961 On the production side, 23 million hoppus feet of timber were cut from the Commission's forests There were reduced pitwood purchases by the National Coal Board, particularly in Scotland, but developments in forest utilization in Britain included the opening of a chipboard factory at Inverness, the addition of a small hardwood pulp mill to a paper mill in Kent, plans for an integrated saw mill and chipboard factory at Thetford and the possibility of a large-scale pulp mill in the Scottish Highlands Two of the significant points which arise out of this report are the utilization developments just mentioned and the help given to private forest owners by the State in the form of planting and management grants (now £1,183,000 a year) and by the Timber Growers' Organization and the Scottish Woodland Owners' Association These two bodies are materially helping to bring more and more management into private forestry and thus increase the productivity Other activities of the Forestry Commission included research, education and the provision for the public of facilities of recreation and amenity

The Royal College of Science and Technology, Glasgow

The annual report for the session 1960–61 of the Royal College of Science and Technology, Glasgow, records the approval by the University Grants Committee of proposals for a new faculty for industrial and social studies (Pp 75 Glasgow The Royal College of Science and Technology, 1962) Such a faculty would include industrial economics, economic history, political theory and institutions and administration, and provide degree courses and facilities for postgraduate study and research, within which the Department of Industrial Administration and General Studies would be integrated The report lists the titles of theses approved for the award of the Diploma of Membership of the College and the Associateship and recent publications by members of the College There are the usual departmental reports, but a brief record of research work in progress, with departmental lists of publications and the titles of theses approved for higher degrees, is issued in a separate *Research Report*

Cost of Books

In the article on "Gas Chromatography" (*Nature*, 194. 822, 1962), Dr. D H Desty, commenting on the book *Gas Chromatography* Second International Symposium held under the Auspices of the Analysis Instrumentation Division of the Instrument Society of America, June 1959 (Academic Press, Inc 16 dollars), wrote "The increase of nearly 50 per cent over the latter [First Symposium] is also somewhat surprising" Mr Kurt Jacoby, vice-president of Academic Press, Inc, New York, writes giving some interesting bibliographical data "First Symposium, edited by Coates *et al*, 1958, 323 pages, 12 dollars, or 0 037 dollars a page, Second Symposium, edited by Noebels *et al*, 1961, 463 pages, 16 dollars, or 0 034 dollars a page Since there was a general price increase in the manufacture of books between 1958 and 1961, the price is both proportionally and actually lower for the Second Symposium" We are pleased to publish this statement from Academic Press, for it is certainly true that publishers have been facing, and are continuing to face, increases in costs of printing, paper, block-making, etc, not all of which are passed on to the book-buyer

Space Bibliography

The diverse literature of space flight is listed and described by F I Ordway III in his *Annotated Bibliography of Space Science and Technology* (Pp x+77 Washington, D C Arfor Publications, P O Box 6285, 1962 2 95 dollars) The bibliography covers the years 1931–61, and aims at including all significant books on the subject in the English language The books are listed according to the year of publication each entry consists of the author, title, full bibliographical details of the American edition and about fifty words of summary After the main list comes an "Astronomical Supplement", which gives, without summaries, books on 'fringe' subjects, the Sun, the Moon, geophysics, etc Finally, there are indexes of authors and titles Mr Ordway's claim that he has listed "all significant English-language titles since 1931" is very nearly true, and his summaries are fair and informative Altogether, this is a most useful reference book, both for librarians and for working scientists

The European Common Market

A THIRD revised edition of the bibliography compiled by J E Wild on *The European Common Market and the European Free Trade Association* has been issued as *Special Subject List No 35* (Pp 64 London The Library Association, 1962 9*s* , L A Members, 6*s* 9*d*) It is in two parts, the first covering books, pamphlets and reports, and the second periodical articles There is also a short list of bibliographies, reading lists, etc There are some 750 entries arranged alphabetically by authors, and also a name and subject index The entries are selected to cover as many aspects of European economic integration as possible, including, for example, scientific manpower, and giving prominence to such controversial matters as agriculture, the Commonwealth problem, competition and sovereignty

The International Commission on Zoological Nomenclature

NOTICE is hereby given of the possible use by the International Commission on Zoological Nomenclature of its plenary powers in connexion with the following cases, full details of which will be found in the *Bulletin of Zoological Nomenclature* (19, Part 4, published on July 16, 1962) (1) Validation and interpretation of the generic name *Endothyra* Phillips, [1846] (Foraminifera) *Z N* (*S*) 768 (2) Designation of a type-species for *Boa* Linnaeus, 1758 (Reptilia) *Z N* (*S*) 1188 (3) Validation and interpretation of the specific name *Culex aegypti* Linnaeus, 1762 (Insecta, Diptera) *Z N* (*S*) 1216 (4) Suppression of the specific name *Pachyodon nucleus* Brown, 1843 (Pelecypoda) *Z N* (*S*) 1470 (5) Validation of the emendations *Dorhynchus* (of *Dorynchus* Thomson, 1873), and *stirhynchus* (of *stirynchus* (*Axius*) Leach, 1815), designation of a type-species for *Callinectes* Stimpson, 1860, validation of the family name Potamonidae Ortmann, 1896, validation of the specific names *Callinectes sapidus* Rathbun, 1896, and *Goneplax sexdentatus* Risso, 1827 (Crustacea, Decapoda) *Z N* (*S*) 1499 (6) Validation of Morch, 1853–1858, *Catalogus Conchyliorum* and designation of a type-species for *Pseudamussium* Morch, 1853 (Pelecypoda) *Z N* (*S*) 1501 Any zoologist who wishes to comment on any of the above cases should do so in writing to the Secretary, International Commission on Zoological Nomenclature, c/o British Museum (Natural History), Cromwell Road, London, S W 7, before January 16, 1963

The Institute of Physics and the Physical Society

AT the second annual general meeting of the amalgamated Institute of Physics and the Physical Society, held in London on July 10, the following were elected to office *President*, Sir Alan Wilson, *Vice-President*, Prof B H Flowers, *Honorary Treasurer*, Dr J Taylor, *Honorary Secretary*, Dr C G Wynne The three new Ordinary Members of the Council elected were Dr D H Follett, Prof M H L Pryce and Prof A M Taylor Prof P M S Blackett, Sir John Cockcroft, Prof W E Lamb, jun , and Prof C F Powell were elected Honorary Fellows in recognition of their eminent work and valuable contributions to knowledge in the field of physics

Natural History Certificate Course

THE University of London awards a certificate of proficiency in natural history This certificate is available to all persons interested in the study of living things in their natural habitats The work involves a directed course of private reading at home, attendance at a practical course of four-weeks duration in the spring and summer, an approved plan of field-work suited to the student's locality to be written up in the form of an essay, and examinations Students wishing to begin their directed course of reading can apply at any time before November 15 for registration with the view of attending next year's practical course which (subject to sufficient entries) will be held at suitable field centres for one week in April and for three weeks in August The regulations and application form can be obtained from the Secretary, Natural History Certificate Course, Department of Extra-Mural Studies, University of London, Senate House, London, W C 1

Grants for Humanities and Social Sciences in Israel

THE Edmond James de Rothschild Memorial Group is offering several fellowships to enable leading authorities in the humanities and the social sciences to spend a period of six months to a year at the Technion–Israel Institute of Technology, Haifa Candidates must be men of recognized academic standing at a university or other institution outside Israel, of sufficient calibre and experience to enable them to assist in the broadening of the basis of the humanities and the social sciences at the Technion They will be expected to deliver a course of lectures in their field of specialization and generally stimulate (and receive stimulation from) the student body and faculty of the Institute Each fellowship-holder will receive a grant of 7,000 dollars per year (or 3,500 dollars for six months), and tourist-class round-trip fare between his home country and Haifa Technion will undertake to provide him with suitable housing for the duration of his stay Application should be made in writing to the Registrar, Technion–Israel Institute of Technology, P O B 4910, Haifa, Israel, before September 1 for the academic year 1962–63, and February 1 for the academic year 1963–64

Symposium on Antarctic Biology

A SYMPOSIUM on Antarctic Biology will be held in Paris during September 2–8 It is being organized by the Scientific Committee on Antarctic Research (S C A R) with the co-operation of the French Academy of Sciences at the Faculté de Médecine, 45 Rue des Saints-Pères, Paris Its aims are to review progress in Antarctic biological research, to discuss the most profitable lines of future research, to integrate Antarctic work with biological research elsewhere, and to discuss the special problems involved in research in the Antarctic and Sub-antarctic, including international co-operation The opening address will be given by Prof P P Grassé, chairman of the Organizing Committee

The following sessions will be held the life sciences in the Antarctic, medical research, microbiology, biogeography and systematics—botany, biogeography and systematics—marine zoology; biogeography and systematics—terrestrial zoology, marine productivity, ecology of invertebrates, ecology of vertebrates, ethology of vertebrates, conservation, animal physiology, future research programmes. About sixty papers will be read. Delegates will attend from Argentina, Australia, Belgium, France, New Zealand, Norway, South Africa, U.S.S.R., the United Kingdom and United States. Further information can be obtained from the Secretary of the British National Committee on Antarctic Research, c/o Royal Society, Burlington House, Piccadilly, London, W.1.

University and College News:

Belfast

THE following appointments have been made at the Queen's University of Belfast: *Lectureships*, F. W. Boal (geography), M. F. Moore (psychology), Dr. A. E. Henderson (zoology), Dr. K. A. Jones (geology).

Melbourne College of Pharmacy

MR. NIGEL MANNING, immediate past-president of the Pharmacy Board of Victoria, has been appointed dean of the College of Pharmacy at Melbourne. He takes up his new post in February 1963. For many years Mr. Manning was lecturer in pharmaceutics at the College. He is at present a partner in a retail pharmacy in Melbourne and is joint editor of the *Australian Pharmaceutical Formulary*. Although the College has been established a number of years, it is now housed in a new building which was opened in March 1960, and has accommodation for more than 600 students.

Sheffield

DR. ALICE GARNETT, reader in geography, has been appointed professor of physical geography, as from October 1. S. A. F. Murrell has been appointed lecturer in metallurgy, and J. A. Whiteman has been appointed to be C. H. Desch Research Fellow.

Southampton

DR. G. J. HILLS, lecturer in physical chemistry in the Imperial College of Science and Technology, has been appointed to the chair of physical chemistry. The following appointments have recently been made to lectureships: L. C. J. Johnson (chemistry), R. Butterfield and A. Coull (civil engineering), A. G. Howsen (pure mathematics), D. Ramsden (physics), A. M. P. Lockwood (zoology). R. M. Laird has been appointed to a research fellowship in chemistry and J. W. Powell to be Vokes Research Fellow in mechanical engineering. Dr. R. E. Parker, lecturer in chemistry, has been appointed secretary and registrar of the Royal Institute of Chemistry.

Announcements

PROF. J. YUDKIN, of Queen Elizabeth College, University of London, has been awarded the William Julius Mickle Fellowship for 1961–62 by the Senate of the University of London for his work on nutrition.

THE Dr. W. S. Bruce Memorial Prize for 1962 has been awarded to Mr. K. V. Blaiklock, in recognition of his contributions by way of navigation to the exploration of the Antarctic continent and for his mapping of lands bordering the Weddell Sea. The Joint Committee of Award for this Prize is nominated by the Royal Physical Society, the Royal Scottish Geographical Society and the Royal Society of Edinburgh, and the Prize is in commemoration of Dr. W. S. Bruce, the Scottish explorer and scientific investigator of polar regions.

AN international symposium on "Chromatography", organized by the Société Belge des Sciences Pharmaceutiques, will be held in Brussels during September 14–15. Further information can be obtained from the Secretary, Société Belge des Sciences Pharmaceutiques, 11 rue Archimède, Brussels 4.

A GENERAL discussion on "High Resolution Nuclear Magnetic Resonance", arranged by the Faraday Society, will be held in the University of Oxford during September 17–19. Subjects under discussion will include: nuclear magnetic resonance in diamagnetic materials, nuclear magnetic resonance in paramagnetic materials, applications to the determination of molecular structure, applications to the study of kinetic processes. Further information can be obtained from the Secretary, the Faraday Society, 6 Gray's Inn Square, Gray's Inn, London, W.C.1.

THE annual summer conference of the Universities Federation for Animal Welfare will be held at Knuston Hall, near Wellingborough, Northamptonshire, during September 14–21. The programme will include talks and discussions on: the humane treatment of laboratory animals, the control of deer, the trapping of fur-bearing animals. Further information can be obtained from Universities Federation for Animal Welfare (Summer Congress), 7a Lamb's Conduit Passage, London, W.C.1.

THE eighteenth International Congress on the History of Medicine will be held in Warsaw and Cracow during September 17–24. Topics under discussion will include: medicine and humanism in past centuries, educational relations between Polish and foreign medical world, medical men who were famous as writers and artists. Further information can be obtained from the Organizing Committee of the Eighteenth International Congress on the History of Medicine, Warszawa, ul. Chocimska 22.

THE eighth Latin-American Congress of Chemistry will be held in Buenos Aires during September 16–22. The Congress will be divided into the following sections: inorganic and radiochemistry, physical chemistry, organic chemistry, biological chemistry, analytical chemistry, food chemistry, pharmaceutical chemistry and pharmaceutical industries, industrial chemistry and chemical engineering, history of chemistry and chemical education. Further information can be obtained from the Secretary, Octavo Congreso Latinoamericano de Quimica, Casilla de Correo 2153, Buenos Aires.

A NATIONAL astronomical convention, arranged by the Rank Taylor Hobson Astronomical Society in collaboration with the Ratcliffe College Astronomical Society, will be held in Leicester during September 7–9. The programme will include: contemporary astronomy (Dr. R. v. d. R. Woolley), some highlights of the 1961 International Astronomical Union meeting (Dr. D. Dewhirst), the design and construction of astronomical instruments (Dr. E. H. Linfoot), the design of radio telescopes (Mrs. P. R. Foster), contributions of radio astronomy to cosmological inquiry (Dr. R. D. Davies), aspects of the history of astronomy (Dr. H. C. King). Further information can be obtained from Mr. V. W. Littlejohn, 19 Southdown Drive, Thurmaston, Leicester.

THE FOREST PRODUCTS RESEARCH LABORATORY

THE Forest Products Research Laboratory of the Department of Scientific and Industrial Research held, during May 29–31, its first open days since the War This Laboratory, which was set up at Princes Risborough in 1927, has the function of carrying out research on all aspects of timber utilization, its interests range from detailed chemical studies of some of the extractives found in timber to engineering work on the production of laminated wood beams About thirteen hundred people visited the Laboratory during the three days, the visitors representing university departments, other research institutions and many industrial and commercial organizations connected with the timber trade or interested in some aspect of timber utilization

Although in the past much of the work of the Laboratory was concerned with determining the properties of imported timbers, about 30 per cent of the present effort is devoted to work on home-grown timbers in collaboration with the Forestry Commission Many exhibits illustrated work in this category Examples of investigations which are specifically linked to home-grown timber are experiments to find a means of preventing the growth of staining fungi in freshly felled softwoods by the development of a suitable spray treatment, the development of methods for preventing attack by ambrosia beetles on softwood logs in the forests of Argyllshire, a trial of the diffusion process for the preservative treatment of impermeable softwoods such as spruce, and the development of techniques for making an assessment of the basic properties of wood by examining small borings 11 mm in diameter taken from the standing tree

This last project is being used to examine the wood in trees which have been provisionally selected, because of certain outstanding features such as stem shape and vigour, to serve as breeding stock for future generations, and the Laboratory is engaged on an examination of the borings from these trees in order to ensure that the basic properties of the wood are satisfactory, and to select those with outstanding properties for a breeding programme The measurements made on the borings include fibre dimensions and density variations, new equipment which enables many measurements of density and variations of density within the tree to be carried out rapidly was on show The method is based on the absorption of β-particles from radioactive carbon-14 in carefully microtomed sections of the borings 100μ thick

Thinnings form a substantial proportion of the yield from any forest plantation and are now in excess of what is required for pit props, fence posts, etc The Laboratory has therefore embarked on a programme of evaluating the quality and yield of paper pulp obtainable from home grown softwoods Equipment for pulping and for measuring basic paper properties was on show together with samples of paper obtained during this work.

The suitability of home-grown timbers for structural purposes was demonstrated by means of a model of the wooden bungalow built by the Forestry Commission at Alice Holt Lodge, Farnham, from Sitka spruce and Scots pine The design was based on working stresses for these timbers obtained during the general programme of assessing home-grown timbers in progress at the Laboratory Conventionally, wood is quality graded by visual assessment of the number and distribution of knots, and working stresses are derived from experimental data obtained on defect-free material suitably adjusted by empirical factors to allow for the effects of natural variability and of knots A prototype machine which measures the working stresses of timber at the rate of 80 ft per min was on show When fully developed and in use this should result in much more rapid and accurate grading and more economic use of timber for structural purposes

Throughout the life of the Laboratory, kiln schedules have been developed which permit commercial timbers to be dried without serious splitting or twisting A new aid to good seasoning practice was demonstrated in the form of an experimental kiln trolley which uses the weight of the load to clamp the timber stack, thus reducing the amount of twisting which can take place during seasoning This will be specially useful with certain difficult timbers

In view of the great amount of energy consumed in cutting wood and the large proportion of a log that is wasted during woodworking operations, the potential value of research in this subject is considerable Equipment designed to measure the forces involved in cutting, and the temperature of a circular-saw tooth during operation were on show

There was a number of exhibits demonstrating work on new methods of manufacturing glued laminated structures These include the use of low voltage, infra-red and radiofrequency heating to set the edges of the glue lines This is achieved after a short period of time and the laminates can then be removed from the jig and the rest of the glue line allowed to set during storage The growing importance of chipboard was evident in research which is being supported by the British Plastics Federation The Laboratory is undertaking a study to evaluate the importance of various factors in the manufacture of chipboard and pilot-scale equipment for investigating various stages of the manufacturing process was on show

A new and patented process for the manufacture of '*Y–D*' spade handles was demonstrated during the open days This development stemmed from the discovery that steamed and compressed wood can be satisfactorily bent after it has been allowed to cool This process, which results in a substantial reduction in losses due to broken bends, is being taken up by several industrial concerns

One of the more important functions of the Laboratory is to ensure that, where appropriate, timber is effectively treated with preservatives to prevent attack by fungi or insects, and methods for assessing the initial toxicity of preservative formulations were illustrated New and improved methods are under investigation, and the Laboratory is co-operating with many European scientists to develop standard methods of test Radiography is being used to assess the rate of development of wood-boring larvæ in treated blocks of wood and X-radiographs on show demonstrated the usefulness of this technique in facilitating work on preservatives

With some timbers it is extremely difficult to obtain penetration of preservative liquid deeply into the wood and a variety of exhibits illustrated work on this problem The rate of flow of an inert gas under a fixed pressure is being used to determine the permeability of wood specimens in the three directions of the grain, and a technique has been developed which enables the process of impregnation under pressure to be studied photographically or by direct observation A short film strikingly demonstrated the variation in the rate of penetration of liquids in different regions of a wood specimen

While the common furniture beetle and the death-watch beetle are widely distributed throughout Britain, the house longhorn beetle (*Hylotrupes bajulus*) causes serious damage only in and around Surrey, and in this area a large increase in damage has been noticed during the past twenty-five years It was illustrated by means of maps that this area coincides with that of the highest mean temperatures during the breeding months of this insect (June–September) It is of some interest that an experiment is being planned in collaboration with scientists in the four Scandinavian countries to explore in a controlled manner the effect of temperature and humidity on the activity of this insect

Wood is used by a few industries on a very large scale and by very many smaller industries in small quantities but in a highly specialized manner The range of problems still to be solved was well illustrated by the exhibits on show on this occasion

E J GIBSON

INTERNATIONAL HYDROGRAPHIC RESEARCH

THE eighth International Hydrographic Conference opened in Monaco on May 8, under the presidency of Prince Rainier of Monaco The opening address was delivered by Rear-Admiral Knox, president of the Directing Committee of the International Hydrographic Bureau, who welcomed delegates from forty-one countries, as well as observers from non-member countries and from international scientific and maritime organizations He expressed gratitude for the generous contributions of data to the Bureau, especially those from the Academy of Sciences of the U S S R and the Woods Hole Oceanographic Institute of the United States Another welcome gift came from Portugal—a complete set of the *Cartographic Monument of Portugal* from an Executive Commission appointed by the Portuguese Government commemorating the five-hundredth anniversary of the death of Prince Henry the Navigator.

The General Bathymetric Chart of the Oceans, which can be seen in the Musée Océanographique in Monaco, was the life-work of the late Prince Albert of Monaco, and therefore is one of the reasons for the Headquarters being in Monaco It is now proposed to complete and print the Chart in such a way as to satisfy the demands of hydrographic officers, oceanographers and others. In national hydrographic offices the bathymetric data is plotted to 1/1,000,000, however, the General Bathymetric Chart of the Oceans is plotted to 1/10,000,000 This has become a financial responsibility of the International Hydrographic Bureau, and it was decided that with co-operation of all State members and other interested agencies, the Chart would be compiled under the auspices of the Bureau

It has become necessary to revise the statutes of the International Hydrographic Bureau and bring them into line with more forward-thinking policies However, before this can be carried out, a decision must be taken concerning the Convention on Juridical Personality At the conference held in 1957 action was started to gain juridical personality recognized, this being necessary before diplomatic status can be requested, as with other international bodies After submission to Foreign Office Ministers, only fifteen signatures of State members were obtained, which was insufficient, twenty-four signatures being required It has now been decided to prepare a convention with a new text, and this will be drafted in Paris, preferably before the end of the present year One interesting and useful matter discussed was the setting up of working committees between the five-year conferences, when work could be set in motion in preparation for discussion at conference-level. Agreement was reached on the importance of studying, together with other bodies, a comprehensive system of classification for documentation covering, principally, hydrography, oceanography, geodesy and allied subjects, with the view of establishing a documentation service

The question of agreement on the velocity to be adopted for all oceanic soundings using echo-sounding apparatus was thoroughly explored, as some standardization is desirable It was agreed that machines be used 'preferably' calibrated for a sounding velocity 820 fathoms (1,500 metres) per second

Progress towards the international adoption of the metric system is very slow, principally on account of the confusion it would cause to navigators of many countries, whose instruments are calibrated in fathoms, and soundings on charts are given in fathoms and feet The International Hydrographic Bureau felt that as yet it is unable to take any effective action since hydrographic offices tend to conform to their national unit of measurement, and until general standardization at an international level has been reached little can be done In the meantime, all countries will endeavour to work towards that goal and report progress every five years

The importance of mean sea-level in the choice of the geoid was the subject of a proposal that the Bureau should be responsible for determining the norms to be followed in the determination of mean sea-level with the ultimate object of standardization for future work of wider scope As this does not fall within the field of hydrography, the Bureau felt that it was not competent to carry out the work It was decided that this study should be transferred to the Permanent Service for Mean Sea Level for consideration and that State members be advised of their reply

A proposal was carried which recommended that, in the terminology of lights in their national language, hydrographic offices adhere as closely as possible to the document entitled *Nomenclature of Lights Used for Marine Navigation*, drawn up by the International Association of Lighthouse Authorities in June 1960 and distributed to hydrographic offices by the Bureau

An exhibition of recent instruments and equipment used in hydrography was prepared for the Conference, and revealed the great advances made in the field of electronics H M S *Vidal* arrived to assist in the demonstration of equipment, and Rear-Admiral Irving, hydrographer of the Navy, headed the British delegation at the Conference A 6-hr cruise was made along the coast when the delegates were given a practical demonstration of a 'Tellurometer' (Vickers) microwave system for use in hydrographic survey, where the master installation is on the ship with known base remote stations ashore It is intended for round-the-clock operations and to save manpower The automatic plotting table provides an automatic plot of the ship's position on a 24-in × 24-in. chart with an accuracy approaching 1 part in 10,000 An enterprising exhibitor chartered a launch for the duration of the Conference to demonstrate a highly accurate radio survey-accuracy position-fixing system The 'Track Plotter' (Decca) provides a pictorial display of the vessel's movements on a special chart; the position-line numbers can at the same time be read from easily defined sequential counters The control operates regardless of visibility and the absence of conventional facilities

A new development also demonstrated was a 'Towed Surveying Asdic' (Kelvin Hughes) This apparatus contains a transducer facing sideways, giving a fan-shaped beam—1½° horizontal plane, 19° vertical plane—of supersonic energy which scans as it is drawn along in the sea The returning echoes make their imprint on an 18-in wide chart, thus providing details of the sea bottom over a swathe 800 yd wide when the depth may be only 30 yd

As with all conferences, there is often a gay beam threading its way between the scientific intricacies. This was admirably demonstrated by one of the closing social events—a dinner given by the Monagasque Government The president of the conference, Ingenieur Général Guggenheim, expressed on behalf of the participants of the conference appreciation of the warm welcome extended to them by the Principality of Monaco, where forty years ago the Bureau was founded He pointed out the work of hydrographers is of an international character and not solely for hydrographic services This aspect was foreseen even before the First World War, but did not materialize until the birth of the International Hydrographic Bureau ALICE KENNEDY

THE INTERNATIONAL BIOLOGICAL PROGRAMME

DURING May 21–22, at Morges, Switzerland, a programme of co-operative research in basic biology on an international scale was outlined by a Planning Committee organized for this purpose by the International Council of Scientific Unions Two years of preliminary discussions by members of the International Council and three of its affiliated Unions—the International Union of Biological Sciences, the International Union of Biochemistry and the International Union of Physiological Sciences—had convinced these scientists that there is a genuine need for such a programme These discussions had further emphasized the fact that, although biologists might derive inspiration and encouragement from the success of the International Geophysical Year, a large-scale programme of intensive research, highly concentrated in a small period of time, is not practicable in the biological sciences The scope of biology is so vast, and affects so many facets of human life, that it could not possibly be covered in a single co-ordinated effort Consequently, the Committee appointed by the International Council of Scientific Unions decided not to attempt to organize a single International Biological Year comparable with the International Geophysical Year

On the other hand, the biologists meeting at Morges, both during preliminary discussions and at the meeting itself, became increasingly aware of the need for an International Biological Programme of a somewhat different nature This need arises from the fact that many problems of vital importance to man's future welfare can be solved only by means of new scientific information Such knowledge can best be acquired through co-ordinated research in basic biological science on an international scale Problems requiring such an international approach have arisen chiefly through the sudden changes in his environment, which man has produced in recent years, as well as the spectacular growth of human populations and the advance of civilization They include man's catastrophic transformation of natural communities of living organisms which often has greatly reduced their productivity, the need for increasing greatly the productivity of living communities all over the world to keep up with the world's growing population, the physiological stresses to which people are exposed because of their rapidly changing ways of life, and the changes in genetic constitution of human populations caused partly by the rapid advance of civilization

As an aid to solving these problems, the Planning Committee outlined a series of interrelated projects, for each of which a detailed programme of research will be prepared by a small sub-committee of scientists selected by the Planning Committee Under the general title of "The Biological Basis of Productivity and Human Welfare", the following specific projects will be organized Three projects will deal with the subject "Biological Productivity of Terrestrial Communities" The first will devote its efforts to a general survey of terrestrial communities The second will study the metabolism of terrestrial communities, particularly photosynthesis, the nitrogen-cycle, and the physiological interrelationships between organisms A third project on terrestrial communities will seek methods of conserving them and increasing their productivity

In addition to the projects concentrating on the land, one project will be devoted to fresh-water communities, and another to the biological resources of marine communities

A group of human biologists, consisting of physiologists and geneticists working in collaboration with each other, will investigate the biological basis of human adaptability, both physiological and genetical

The size and scope of these projects, as well as their duration, will be worked out by the sub-committees, which are now being appointed by the Planning Committee

Prof G Montalenti (University of Rome), convenor of the Planning Committee, expressed great satisfaction with the outcome of the conference He announced that detailed plans for each of the proposed projects should be ready for consideration by the Central Planning Committee early in 1963, after which they will be submitted to biologists in all the nations which are members of the International Council of Scientific Unions for further revision, financial support and for co-operation in organizing the actual teams of research workers

Similar optimism was expressed by other members of the Planning Committee These included the following the International Council of Scientific Unions was represented by its vice-president, S Horstadius (Uppsala, Sweden), and F W G Baker, who acted as secretary of the conference Representing the International Union of Biological Sciences were its president, C H Waddington (Edinburgh), general secretary, G L Stebbins (Davis, California), Jean Baer (Neuchâtel), of its Division of Zoology, and D Steinberg (Leningrad) The International Union of Biochemistry was represented by its president, M Florkin (Liège), the International Union of Physiological Sciences by J S Weiner (Oxford), and the International Union of Geography by H Boesch (Zurich)

Although the research to be carried out under the International Biological Programme will be entirely in fields of basic biology, it will be oriented toward solving practical problems of human welfare For this reason the conference was attended by the following consultants S J Holt, representing the Food and Agriculture Organization of the United Nations, R L Dobson, of the World Health Organization, and H Seligman, representing the International Atomic Energy Association The advice of consultants from these organizations will be frequently sought by sub-committees for each project, while making their plans

Interest in the Programme has been expressed by the officials of Unesco, whose representative, A Kepes, attended the conference The co-operation of the Organization is assured, particularly for those aspects of the programme which involve the training of additional research workers to carry on the work of the projects

Because of the importance of the Programme for the conservation of natural communities throughout the world, the International Union for the Conservation of Nature acted as host for the conference, which was held at its headquarters, Les Uttins, at Morges In addition to its president, Jean Baer, a member of the Planning Committee, the International Union for the Conservation of Nature was represented at the conference by two consultants, E M Nicholson (London) and E H Graham (Washington, D C)

At the conclusion of the session, General G Laclavère, treasurer of the International Council of Scientific Unions, discussed with the conference members his experiences with the planning stages of the International Geophysical Year, and gave many helpful comments on procedure He expressed great satisfaction with the work accomplished by the Committee

THE CARNEGIE UNITED KINGDOM TRUST

THE forty-eighth annual report of the Carnegie United Kingdom Trust for 1961* covers the first year of a new quinquennium in which new policies included schemes for the distribution of allocations for pioneer projects in new communities and for the benefit of youth projects Few applications, however, have survived the assessment of innovation, but a good start has been made with the award of grants for youth club improvements, for which 44 grants, totalling £6,216, were offered Payments during the year amounted to £152,533, and at the end of the year £541,315 was committed to projects maturing during the quinquennium £45,000 has been allocated for continuance during the quinquennium of the policy of aiding the development of the museum and art gallery services During the year expert reports were commissioned on 25 museums and development grants offered to 13 on which reports had been earlier approved

In a final statement on the distribution during 1957–61 of £194,123 in improvements grants to nearly 1,500 village halls, for which purpose the Trust has now spent some £371,520 in grants for 2,156 schemes, the report refers particularly to the special difficulties of tiny communities on small Scottish islands During 1956–61 the Trust also provided £3,856 to finance the installation of film projection equipment in 16 remote communities where it was difficult or impossible for the Highlands and Islands Film Guild to provide a mobile service

Dr J H Nicholson's study of the social problems of new communities was issued in a report published in August 1961 under the title *New Communities in Britain Achievements and Problems*, and Dr Nicholson's recommendations are detailed in the Trust's report Although no grants were made during the year for pioneer projects to provide social amenities in new communities, some *ad hoc* grants made to new communities are now producing results At Cumbernauld encouraging progress is reported in dealing with problems that face families transported into developing new communities The Bristol Social Project was finally terminated in 1961 and a report on the work and a pamphlet containing a personal interpretation of the results by Prof R Wilson, chairman of the Projects Committee, are expected to appear in 1962 The year also saw the end of the Trust's responsibility for the Liverpool Personal Service Society's experiment in rehousing selected homeless families in rehabilitation houses under case-work supervision, a report on the inquiry into the needs of families with handicapped children is also in the press The Trust is spending £45,000 on two projects, one for establishing a centre at Shrewsbury providing a training and educational group for children aged two and upwards, a centre for continuing assessment, focus for a counselling assessment, and an information centre and meeting ground for parents, and the other for a centre in Glasgow where a child-welfare clinic, a handicapped children assessment centre and a day nursery for handicapped children will be placed under one roof

Although grants for education totalled only £19,670 during the year, they cover some interesting projects The David Marshall Lodge, Aberfoyle, in the Queen Elizabeth Forest Park, is now out of the responsibility of the Trust, but the Trust is hopeful of achieving an attractive scheme in the Brecon Beacons National Park for a sheltered viewpoint and picnic rendezvous, with facilities for the national park's warden and information services The decline in applications for field-study bursaries continued and only 79 people received help at a cost of £237 Ten grants for field work in archæology by amateurs working under skilled direction were promised to a total of £562, and four applications for assistance in field work by local groups of amateurs in natural history were approved, with a total commitment of £279 A grant of £500 a year for the years 1962–65 was offered to the Royal Meteorological Society to maintain its programme of courses for amateurs at the level achieved in 1961, the Conservation Corps founded by the Council for Nature in 1959 is to receive grant assistance from the Trust, totalling £14,500 over five years until 1963

---

* The Carnegie United Kingdom Trust 48th Annual Report, 1961 Pp viii – 76 (Dunfermline, Fife The Carnegie United Kingdom Trust, 1962)

HEALTH IN THE AMERICAS

HEALTH conditions in the Americas, especially in Central and South America, have recently been reviewed (*WHO Chronicle*, 1, No 50, 1962) Latin America has a rapidly growing population By 1980 that of South America may reach 234 million and that of Central America 115 million, the combined population of 349 million exceeding by nearly 80 million the estimated population of the United States and Canada for that date The population of Latin America is young, approximately 40 per cent being less than 15 years of age and only 3 per cent 65 years and more By comparison, only 27 per cent of the population of the United States is less than 15 years of age, while 8 per cent is 65 years and more

Birth-rates in Latin America are high—more than 40 per 1,000 population in many countries, and in general exceeding 30 per 1,000 Death-rates in infancy and early childhood are also high Whereas, in the United States, the death-rate for this period of life is 1 1 per 1,000 population, in all except two of the Latin American countries with accurate data available, it was at least eight times as high in 1956, and in one it was nearly forty times as high These high death-rates are closely correlated with high rates of illness In Guatemala City, for example, children less than 5 years of age accounted for 28 per cent of patient-days in hospital, their average length of stay being more than twice as long as that of other patients

Among the communicable diseases which exact their toll in the Americas, malaria, smallpox, yellow fever, tuberculosis, leprosy, the venereal diseases and the zoonoses are all important

Malaria The original malarious area of the Americas, covering 16,083,000 km, contained a population of 142,702,000 in mid-1960 Of this population, 38 per cent lived in areas from which it was claimed that malaria had been eradicated and 7 per cent in areas where the consolidation phase had been reached Some 37 per cent lived in areas where eradication was in the attack phase, and 14 per cent in areas where the eradication campaign had not yet begun Four thousand, seven hundred and ninety-two cases of smallpox were reported from seven countries

Aedes aegypti, the vector of urban yellow fever, has been eradicated in Bolivia, Brazil, British Honduras, the Canal Zone, Chile, Colombia, Costa Rica, Ecuador, El Salvador, French Guiana, Guatemala, Honduras, Nicaragua, Panama, Paraguay, Peru and Uruguay, and in other countries such as Mexico and Argentina the programme is making progress The main problem at present is the continued existence of the mosquito in the United States and in some of the Caribbean Islands Fifty cases of jungle yellow fever were reported in 1960 from Bolivia, Brazil, Colombia, Peru and Venezuela, 30 being from Bolivia Although this disease is not amenable to the measures used in the eradication of urban yellow fever, elimination of the urban vector removes the risk of its spread

Although diagnostic facilities and reporting of cases of tuberculosis are less advanced in Latin America than in North America, relatively more new cases are reported in the former, and death-rates there in 1959 were at least three times greater Reporting has improved, but, despite this, the number of cases reported is declining everywhere Tuberculosis still remains one of the principal causes of death in Latin America, however

In 1958, there were nearly 10,000 new cases of leprosy distributed over 13 countries and 13 territories Approximately 200,000 persons are known to be suffering from leprosy in the Americas, and, if all cases were registered, this number would be higher In Latin America at present, more than 30,000 beds or 2½ per cent of existing hospital beds, are in leprosaria or leprosy units

Both syphilis and gonorrhœa are serious health problems in most Latin American countries Death-rates from syphilis and its sequelæ, including cardiovascular syphilis and syphilitic psychoses, are higher in more than half the Latin American countries than in the United States In one country the rate is more than four times as high

The zoonoses are widespread in the Americas Rabies is to be found in all countries of the region, except Uruguay, the total number of cases reported in man in 1958 being 176, in animals more than 7,000 Brucellosis also occurs widely in man and animals Testing of sample herds in Mexico showed that up to 68 per cent of the animals were reactors, and similar testing in Brazil showed a proportion of 57 per cent A Mexican authority estimates that there are 20,000 human cases due to *Brucella melitensis* in Mexico every year

In the twenty countries of Latin America, 33 million city dwellers, or 39 per cent of the urban population, in 1961, were without water from a community water supply Smaller cities and rural areas are even worse off It is estimated that 100 million persons in Latin America need proper water supplies This situation results in unfavourable living conditions, a high incidence of gastro-intestinal disease, and hampers industrial development

In Latin America most cities have no adequate sewage disposal facilities, and in rural areas many houses lack any kind of facilities for the disposal of excreta Little attention has hitherto been paid to water- or air-pollution or to the public health aspects of housing or municipal planning Measures to control industrial accidents and occupational diseases are unknown or just beginning to be introduced, and yet, as investigations in 13 Latin American republics have shown, there is a high incidence of sickness in industry and large sums have to be paid out in compensation. On the average, the cost of disability among the gainfully employed amounts to approximately 15 per cent of the national income.

Nutritional deficiencies are common in Latin America. In 10 countries, the average calorie consumption ranged from 1,960 to 3,100 calories daily in 1957. In some areas the animal protein available is less than 10 gm. per person per day. Cereals often provide up to 78 per cent of the total protein. As a result of the low consumption of good-quality protein, specific deficiency diseases, lack of resistance to infection, and poor physical development are often found. Inadequate consumption of necessary foodstuffs is to be attributed largely to lack of purchasing power and lack of understanding of the value of certain foods.

Dental caries affects more than 90 per cent of the adult population and there is no hope of increasing the number of dentists rapidly enough to carry out adequate treatment. The emphasis has thus been on prevention. Fluoridized water supplies are not found in 43 cities in Latin America.

In no country of the Americas are funds now available to build or to staff and maintain hospitals for the institutional care of all the mentally ill needing such care. In many countries, such as the United States, nearly half the number of hospital beds are in mental institutions. In Latin America, approximately 20 per cent are in mental institutions, the number varying from 0.1 to 1.5 per 1,000 population.

A METHYL ANALOGUE OF COBAMIDE COENZYME IN RELATION TO METHIONINE SYNTHESIS BY BACTERIA

By Dr. J. R. GUEST, Dr. S. FRIEDMAN* and Prof. D. D. WOODS, F.R.S.
Microbiology Unit, Department of Biochemistry, Oxford

AND

Dr. E. LESTER SMITH, F.R.S.
Glaxo Research, Ltd., Greenford, Middlesex

PREVIOUS investigations at Oxford into the biosynthesis of methionine by cell-free extracts of several strains of *Escherichia coli* have given strong evidence that there are two mechanisms for the final methylation of homocysteine[1–3]. One of these operates in many strains of the organism (for example, *PA*15, a serine/glycine auxotroph), but is absent from auxotrophs with an alternative growth requirement for vitamin B_{12} or methionine; it is independent of vitamin B_{12}, but has a strict requirement for a conjugated form of folic acid (for example, tetrahydropteroyltriglutamate, H_4PtG_3) as coenzyme for the transfer of the one-carbon unit from serine or formaldehyde, the ultimate source of the carbon of the methyl group. The second mechanism depends on the presence of a vitamin B_{12}-containing enzyme (B_{12}-enzyme) and can utilize either H_4PtG_3 or tetrahydropteroylmonoglutamate (H_4PtG) as co-factor; it is the obligatory pathway in vitamin B_{12}/methionine auxotrophs (for example, strain 121/176) and can be evoked in other strains by the addition of vitamin B_{12} either to the growth medium or to ultrasonic extracts.

The B_{12}-enzyme takes part in the overall enzymatic transfer of a methyl group from a methylated tetrahydrofolate (probably N^5-methylH_4PtG (refs. 4–6) to homocysteine[3]; $NADH_2$, FAD, ATP, Mg^{2+} and other enzymes (present in several other strains of *E. coli* tested) are also required. The reaction (a specific transmethylation) clearly differs from the isomerase reactions of the type catalysed by the known coenzyme forms of vitamin B_{12} (the cobamide coenzymes). The discovery[7] of a method for the chemical synthesis of these coenzymes and their analogues made possible metabolic investigations with the methyl analogue of dimethylbenzimidazolylcobamide coenzyme, that is, the analogue with a methyl group replacing the 5′-deoxyadenosyl group linked to the cobalt. The analogue was prepared[7] by the action of dimethyl sulphate or methyl iodide on fully reduced hydroxocobalamin and was purified by passage through DEAE- and CM-cellulose columns in series and crystallized from aqueous acetone. For brevity this analogue will be referred to as 'methylcobalamin'.

When homocysteine was incubated with 'methylcobalamin' there was a slow spontaneous reaction yielding methionine. The rate of this reaction was increased at least ten times by a purified (hundred-fold) preparation[8] of the B_{12}-enzyme (Table 1); the differential between spontaneous and enzyme-catalysed reactions could presumably have been increased by increased enzyme concentration since the rate of the reaction was directly proportional, over the range tested, to the concentration of enzyme (Fig. 1). Continuing spontaneous formation of methionine after incubation with the enzyme had ended was prevented by oxidizing the residual homocysteine. Reaction mixtures were heated at 100° for 10 min. and cooled; after adding 0.1 ml. of 6 per cent (w/v) hydrogen peroxide the mixture was stood for 15 min. at room temperature. Residual hydrogen peroxide was removed by treatment with catalase (0.1 ml. of 8 μM) for 10 min. and the enzyme then destroyed by heating at 100° for 10 min. This procedure did not reduce the recovery of added methionine; the test organism in the microbiological assay used[9] responds equally to methionine and its sulphoxide.

Maximum enzymatic formation of methionine occurred over the range *p*H 7.4–8.7, and no substrates or co-factors were required other than homocysteine and 'methylcobalamin' (Table 1). The reaction proceeded linearly with time up to the limit tested

---

* Fellow of the U.S. National Foundation.

Table 1 FORMATION OF METHIONINE FROM HOMOCYSTEINE AND 'METHYLCOBALAMIN'

Addition or modification	L-Methionine formed (mμmoles)
None	9*
B_{12}-enzyme	188
B_{12}-enzyme + 'co-factors'	113
B_{12}-enzyme (aerobic incubation)	100
B_{12}-enzyme (heated 3 min at 100°)	14
Albumin (0 5 mg)	17

* Zero if 'methylcobalamin' was omitted, indicating 9 mμmoles were formed by the non-enzymatic reaction

The reaction mixture contained 'methylcobalamin' (0 7 μmoles), DL-homocysteine (7 5 μmoles), mercaptoethanol (10 μmoles), potassium phosphate buffer, *p*H 7 8 (160 μmoles), B_{12}-enzyme (12 units, ref 8) in a volume of 1 ml The 'co-factor' mixture contained alcohol dehydrogenase (0 15 mg) and (μmoles) FAD, 0 1, ATP, 1 0, $MgSO_4$, 1 0, DPN, 2 0, ethanol, 45 Incubated 1 5 h at 37° under hydrogen

(3 h), but the rate was almost halved by aerobic incubation (Table 1) Quantitative yields of methionine in terms of the methyl group of 'methylcobalamin' were obtained in the presence of excess homocysteine, and the colour of the reaction mixture changed from red to the brown characteristic of vitamin B_{12r} (ref 10) It is not, however, possible to designate the latter as a product of the reaction because it could be formed from hydroxocobalamin and the sulphydryl compounds present in the reaction mixture

The fact that hydroxocobalamin was inactive in the reaction described above provides indirect evidence that the methyl group of 'methylcobalamin' transferred to homocysteine is that linked to the cobalt and not one of those present as side groups on the corrin ring Direct confirmation was obtained by the use of [Me-^{14}C] 'methylcobalamin', which was prepared from $^{14}CH_3I$ (4 7 μc /μmole)[7] After incubating this with B_{12}-enzyme and L-homocysteine the methionine formed was isolated free from B_{12}-derivatives by developing descending chromatograms on paper with *n*-butanol/acetic acid/water (4 1 5) The eluted methionine was diluted with inactive carrier methionine and recrystallized to constant specific activity Degradation by the technique given by Sakami[11] showed that carbon-14 was present principally in the methyl group (Table 2)

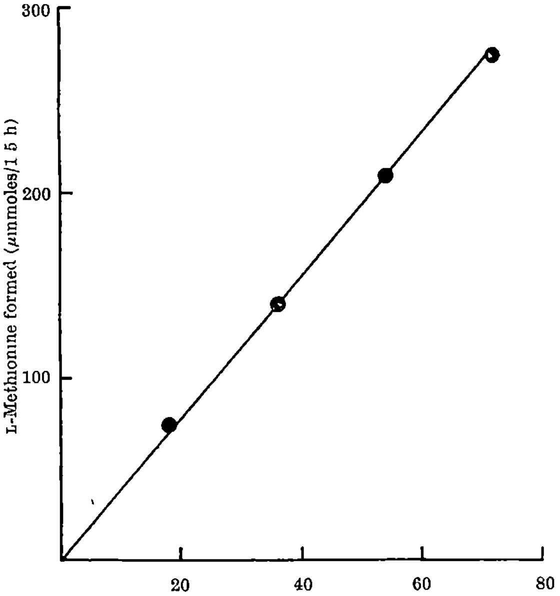

Fig 1 Effect of enzyme concentration on the formation of methionine

Conditions as in Table 1, except that the amount of B_{12}-enzyme was varied The amount of methionine formed non-enzymatically during the period of incubation (10 μmmoles) has been deducted

Table 2 INCORPORATION OF [Me-^{14}C] 'METHYLCOBALAMIN' INTO METHIONINE

	Specific activity (counts/min/μmmole)
'Methylcobalamin'	2,660
Methionine isolated	2,450
Methyl group of methionine (as tetramethylammonium iodide)	2,220

The specificity of the enzymatic reaction was examined qualitatively by chromatography 'Ethylcobalamin' (prepared by an analogous method to that used for the methyl derivative) and dimethylbenzimidazolylcobamide coenzyme ('5′-deoxyadenosylcobalamin' in the present terminology) were each incubated with homocysteine and crude or purified preparations of the B_{12}-enzyme, there was no significant formation of ethionine or *S*-adenosylhomocysteine, respectively 'Ethylcobalamin', however, caused a 65 per cent inhibition of methionine formation from 'methylcobalamin' when present at three times the concentration of the latter No *S*-methylcysteine was detected when 'methylcobalamin' was incubated with the enzyme and cysteine instead of homocysteine, and only traces of *S*-adenosylmethionine when '5′-deoxyadenosylcobalamin' was incubated with methionine The enzyme is thus relatively specific for both donor and acceptor substrate

'Methylcobalamin' was four times more effective than any other cobalamin derivative tested in promoting the *in vitro* formation of B_{12}-enzyme from a crude source of apo-enzyme in the absence of a reducing system, when the latter was present 'methylcobalamin' and hydroxocobalamin were equally active and superior to cyanocobalamin (Table 3)

Table 3 FORMATION *in vitro* OF B_{12}-ENZYME

Cobalamin derivative added	B_{12}-enzyme formed (units) with reducing system Absent	Present
Hydroxocobalamin	6	22
Cyanocobalamin	2	12
'Methylcobalamin'	22	24
'5′-Deoxyadenosylcobalamin'*	4	4
Sulphitocobalamin	4	5
None	1	1

* Dimethylbenzimidazolylcobamide coenzyme

The cobalamin derivative (1 2 μmmoles) was incubated for 30 min at 37° under hydrogen with an ultrasonic extract of *E coli PA*15, which had been dialysed and treated with 'Dowex-1' resin The total volume of the reaction mixture, which also contained 200 μmoles of potassium phosphate buffer, *p*H 7 8, was 2 7 ml The reducing system contained alcohol dehydrogenase (0 3 mg) and (μmoles) FAD, 0 2, DPN, 3, ethanol, 90 Samples (0 6 ml) of the reaction mixture were assayed (ref 12) for B_{12}-enzyme in the presence of the anilide analogue of the vitamin

One possible interpretation of these results is that 'methylcobalamin' exists in a transient state as the prosthetic group of the B_{12}-enzyme in the B_{12}-dependent pathway for the methylation of homocysteine, and that oxidized, reduced and methylated forms of cobalamin occur successively during the action of the enzyme The fact that reduced cobalamin is labile to oxygen (and 'methylcobalamin' to light) perhaps explains why the form in which cobalamin has so far been isolated by us from purified B_{12}-enzyme is mainly hydroxocobalamin, sometimes with traces of a more cationic form[13]

An alternative possible mechanism for the new reaction demonstrated in this communication is that the apo-enzyme of the B_{12}-enzyme combines with 'methylcobalamin' to yield a complex that transfers the methyl group to homocysteine and at the same time dissociates liberating the de-methylated cobalamin (which may undergo secondary changes), and the apo-enzyme which then combines with another molecule of 'methylcobalamin' Since, however, vitamin B_{12} derivatives are in general strongly bound to protein, it is also possible that 'methylcobalamin' transfers its methyl group to whatever form of vitamin B_{12} is the prosthetic group of the B_{12}-enzyme, with resultant methylation of either the cobalt atom or of one of the methene bridge carbons of the corrin ring[14], the methyl group is finally envisaged as passing to homocysteine

'Methylcobalamin' could only act catalytically (either as the prosthetic group of B_{12}-enzyme or as a free intermediate) in the overall methylation of homocysteine by serine if there were a mechanism for its reconstitution from the de-methylated cobalamin derivative and *N*-methyltetrahydrofolate Further work on this aspect is in progress In this connexion it may be noted that both methionine synthesis mediated by the B_{12}-enzyme and the synthesis of cobamide coenzyme by extracts of *Propionibacterium shermanii*[15] and *Clostridium tetanomorphum*[16] require the presence of a reducing system containing a flavin derivative, this suggests that in all these processes reduction of cobalamin must precede substitution, as it does also in the chemical synthesis of the coenzyme and its methyl analogue[7]

Finally, it should perhaps be recalled that, in strains of *E coli* that are not vitamin B_{12} auxotrophs and when H_4PtG_3 is the folic acid coenzyme (and its N^5-methyl derivative the immediate methyl donor) the methyl group is transferred to homocysteine without the necessity for the presence of a B_{12}-enzyme, of reducing conditions or of ATP[3]

CONDITIONS FOR ESTABLISHING IMMUNOLOGICAL TOLERANCE TO A TUMOUR VIRUS

By Prof H RUBIN

Department of Virology, University of California, Berkeley

THE viruses that are responsible for the avian leukosis complex of neoplasms can be transmitted from hen to progeny through the egg[1,2] When a virus of this group is thus congenitally transmitted, it multiplies extensively throughout the embryonic and post-embryonic life of the affected chicken[3,4] The congenitally infected chicken gives no sign of immunological responsiveness to the virus either by the production of neutralizing antibody or elimination of the virus from the blood Since it is fully competent to produce antibody to other antigens, such as influenza virus, it is considered to be specifically tolerant to the congenitally transmitted virus

Uninfected chicks placed in contact with congenitally infected chicks develop a transient viræmia which is almost invariably followed by antibody production[4] The sharp distinction between the consequences of congenital and of contact infection suggested that deliberate infections of embryos and young chicks at closely spaced intervals of time could be used to define more precisely the factors involved in producing the alternative states of immunological tolerance or responsiveness to the virus The experiments to be described show that tolerant infection with an avian leukosis virus can be produced in chickens by deliberate infection of the embryo The chief requirement for eliciting immunological tolerance rather than responsiveness in a chicken is that the virus multiply to a high level during the first few weeks of life after hatching

The leukosis virus used in the work described here is known as 'resistance-inducing factor' (RIF), because it is assayed by interference with the growth of Rous sarcoma virus (RSV)[2] The RIF stock was obtained from the plasmas of congenitally infected chickens and had 1–2 × 10^6 infectious units per ml The birds used were of the Kimber Farms strain 813 in which the incidence of leukosis is low My experience with this strain indicates that only about 1 in 50 embryos is naturally infected with RIF Up to the sixth day of embryonic incubation infection was carried out by direct inoculation of the embryo or into the yolk sac From the ninth day onward, inoculation was either intra-embryonic or intravenous After hatching, inoculation was either intraperitoneal or intracardiac Unless otherwise stated, the inoculum was 0 1 ml of undiluted RIF stock and therefore contained 1–2 × 10^5 infectious units

Heparinized blood was obtained from each chick one week after hatching and every other week afterwards The plasma was tested for the presence of RIF by the induction of interference with RSV in cultures of chick embryo cells When cultures were infected with plasmas containing more than 10^5 infectious units of RIF per ml , and challenged with RSV on transfer 4–5 days later, there were less than one-tenth as many RSV foci as in control cultures uninfected with RIF Plasmas with approximately 10^3–10^5 and 10^1–10^3 infectious units of RIF induced comparable reductions in RSV foci in chick embryo cultures challenged after 2 and 3 transfers, respectively

The presence of antibody to RIF was detected by neutralization of RSV The validity of this procedure is based on the fact that RIF and RSV have cross-reacting antigens, and that the neutralizing activity of a serum against one of these viruses is roughly proportional to its activity against the other[3,4]

The testing of repetitive bleedings showed that the chickens could be divided into three categories according to their immune response to infection The first category consisted of birds which had become immunologically tolerant to RIF These birds had a high-level viræmia (1–2 × 10^6 infectious units of RIF per ml plasma) which showed no signs of subsiding by the final bleeding made at 16 weeks of age At no time was there any evidence of antibody to RIF or RSV

The second category, designated as partially tolerant, consisted of only a few birds They had levels of RIF which ultimately reached a fairly constant level between 10^3 and 10^5 per ml of plasma (that is, interference with RSV did not become evident until infected cultures had been transferred twice) Birds in this group occasionally had low levels of antibody to RSV concurrently with low levels of RIF

The third category consisted of birds which had a transient viræmia followed by the appearance of antibody This group was fully competent to react immunologically to the viral antigens

Age at Inoculation and Induction of Tolerance An experiment was carried out to determine the effect of age and route of infection on the induction of tolerance to the virus Inoculations were made by various routes into embryos and chickens up to 43 days after hatching In Table 1, the outcome of infection of the various groups is represented It can be seen that the yolk sac was an inefficient route for inducing tolerance In fact when the yolks of six freshly laid eggs were inoculated with RIF no evidence of virus growth was obtained, that is, neither tolerance nor immunity ensued when the birds became immunologically mature

Table 1 EFFECT OF THE ROUTE AND AGE OF INOCULATION ON THE IMMUNE RESPONSE

Route of inoculation	Day of infection	No inoculated	Tolerant	Partially tolerant	Immune
Yolk sac	0 day embryo	6*	0	0	0
	3 ,, ,,	4	2	0	2
	6 ,, ,,	6	1	2	3
Intra-embryo	4 ,, ,,	7	7	0	0
	10 ,, ,,	5	4	0	1
	17 ,, ,,	2	1	0	1
Intravenous	9 ,, ,,	4	3	0	1
	13 ,, ,,	3	2	1	0
Intracardiac	1 day after hatching	3	2	1	0
Intraperitoneal	,, ,, ,, ,,	8	0	1	7
	15 days ,, ,,	7	0	0	7
	43 days ,, ,,	7	0	0	7
Totals		62	22	5	29

In each case, 0 1 ml of undiluted RIF stock containing 1–2 × 10^6 infectious units was inoculated Blood samples were obtained every other week beginning at one week after hatching and continuing until the 16th (or, in a few cases, the ninth) week after hatching All plasmas were tested for RIF and antibody to RSV

*There was no evidence of successful virus multiplication in any of the 6 embryos inoculated by the yolk sac route at 0 days, that is neither tolerance nor immunity developed

Out of 10 chickens infected in the yolk sac at 3 and 6 days only three developed tolerance to RIF while two became partially tolerant and five developed immunity The inefficiency of the yolk sac route in producing tolerant infection was probably due to a combination of the high viscosity of yolk and the presence in yolk of maternally transmitted antibodies The high viscosity prevents free movement of virus particles to sites at which they can multiply and allows ample opportunity for inactivation by antibody and heat

Direct inoculation of the embryo with RIF at 4 and 10 days of incubation resulted in tolerant infection in almost all (11 of 12) chickens Infection of 17-day-old embryos by this route seemed to be less efficient in establishing tolerance than earlier infection, but the small number of birds in this group was insufficient for a secure evaluation

Intravenous infection of embryos at 9 and 13 days of incubation led to tolerance in most (5 of 7) of the chickens, but partial tolerance and immunity followed in a few

Attempts to induce tolerance by infection after hatching were generally unsuccessful Only intracardiac infection at one day resulted in some tolerant infections (2 of 3) Intraperitoneal infection at one day resulted in immunity in most (7 of 8) birds and only a partial tolerance in one bird All infections at 15 and 43 days after hatching resulted in immunity These results showed that early infection was required to produce tolerance to RIF

Level of Virus Multiplication and Induction of Tolerance The failure to induce tolerance by the yolk sac route, despite early infection, indicated that the age of the chickens at the time of inoculation was not the sole factor in determining the type of immunological reaction in the host Inspection of the levels of viræmia and of antibody during the first 3 weeks after hatching indicated that the virus had to multiply to high concentrations in the young chick in order to establish a tolerant infection This requirement is evident from the results illustrated in Fig 1, where representative birds from the groups inoculated at different ages have been regrouped according to the outcome of infection These selected case- and group-histories are representative of the various levels and times of virus multiplication which culminate in tolerance or immunity

It can be seen from Fig 1 that the attainment of a high-level viræmia by the first week after hatching (class *A*) assured a tolerant infection A low-level viræmia in the first week (classes *B*, *C*, *D*, *F*, *G*) assured a high level of virus multiplication by the third week, but occasionally resulted in a partial rather than full tolerance (classes *F*, *G*)

Birds, the sera of which were free of detectable virus at one week but which had developed heavy viræmia by 3 weeks (classes *E*, *H*, *I*, *J*, *K*), had about an equal chance for developing tolerant or immune infection Some birds in this group which developed an immune response did so despite persistence of the high-level viræmia through the fifth week (classes *I*, *J*, *K*)

All birds which failed to reach high levels of viræmia by the third week developed immune infections

Table 2 EFFECT OF THE TIME AND LEVEL OF VIRUS MULTIPLICATION DURING THE FIRST 3 WEEKS OF LIFE ON THE IMMUNE RESPONSE

Conditions leading to	Viræmic level after hatching		Immunological outcome		
	1 week	3 weeks	Tolerant	Partially tolerant	Immune
Tolerance	+++	+++	16	0	0
	++	+++	7	2	0
	++	++	1	0	0
	+	+++	1	0	0
Tolerance or immunity	—	+++	4	1	3
Immunity	—	++	0	0	6

+++ = >10^5 infective units RIF per ml plasma , ++ = 10^3–10^5 infective units RIF per ml plasma , + = 10–10^3 infective units RIF per ml plasma , — = < 10 infective units RIF per ml plasma

The results are compiled from several experiments Birds which failed to develop detectable viræmia by the third week after hatching are not included , all such birds developed an immune response

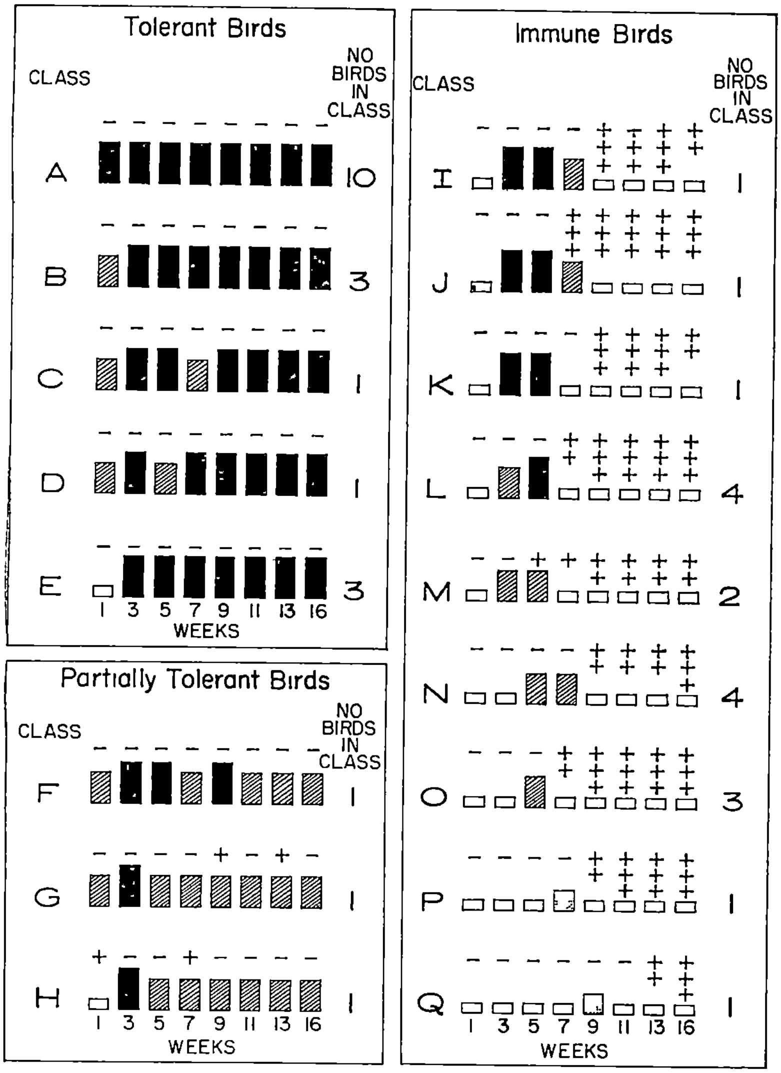

Fig 1 Relation between course of virus multiplication and immune response Representative birds have been selected from the experiment of Table 1 to illustrate in detail the range of situations with regard to viræmia and antibody which leads to tolerance or immunity Only those birds infected as embryos or on the first day after hatching are included

Antibody-levels

Symbol	RSV survivors after exposure to 1 10 dilution of plasma	Interpretation
–	0 5–1	No antibody
+	0 2–0 49	Weak antibody
+ +	0 1–0 19	Moderate antibody
+ + +	< 0 1	Strong antibody

Viræmic-levels

Symbol	Transfer at which plasma-infected culture became resistant to RSV	Interpretation
White	Remained sensitive through three transfers	Negative for RIF (< 10^1 infectious units/ml)
Stippled	Third transfer	Low RIF concentration (10^1–10^3 infectious units/ml)
Oblique shading	Second transfer	Moderate RIF concentration (10^3–10^5 infectious units/ml)
Black	First transfer	High RIF concentration (> 10^5 infectious units/ml)

(classes *L–Q*) Viræmia was never detectable in more than two successive bleedings in such birds, and was of a low or moderate level Antibody became detectable 2–4 weeks after the viræmia was first detected, and persisted indefinitely

Relevant data from several experiments is condensed in Table 2 Here again, it can be seen that a bird with viræmia at one week was almost certain to become tolerant to RIF Birds negative at one week but heavily viræmic at three weeks had an even chance for developing tolerance or immunity Birds negative at one week and only moderately viræmic by the third week became immune All birds which developed viræmia later than three weeks became immune

Inoculation Dose and the Induction of Tolerance The results described in the preceding section demonstrate that high concentrations of virus must be produced within the first few weeks after hatching to establish a tolerant infection with RIF Since it has been demonstrated that the initial growth-rate of RIF is a function of the infecting dose[2], it was anticipated that a reduction in the dose inoculated into the embryo would delay the appearance of a high-level viræmia and thereby lower the frequency of tolerant infections That this is indeed the case was demonstrated in the following experiment

Eleven-day-old embryos were infected intravenously with ten- and one hundred-fold dilutions of the RIF stock The inocula represented approximately 10^4 and 10^3 infectious units of RIF, respectively Beginning at one week after hatching, the birds were bled every other week until the ninth week This termination-time was chosen because the previous experiment had shown that a constant level of viræmia characteristic of a bird for its life-time was reached by nine weeks after hatching in those individuals which had been infected as embryos

The results of this experiment are presented in Fig 2. It can be seen that all five birds which received the 1 10 dilution of virus developed a viræmia at one week which led to tolerant infection, while this occurred in only one of the four receiving a 1 100 dilution of the virus In the remaining three birds receiving the 1 . 100 dilution, viræmia did not become detectable until the third week or remained undetected When the viræmia occurred in these birds it was of a low level and transient, and was followed by appearance of antibody Thus, it is clear that reducing the size of the virus inoculum delayed development of viræmia and resulted in immune rather than tolerant infection

The results of this investigation show that high levels of virus multiplication must be reached during the first few weeks after hatching if a tolerant infection with RIF is to be established in chickens Because of the slow multiplication of RIF, it is

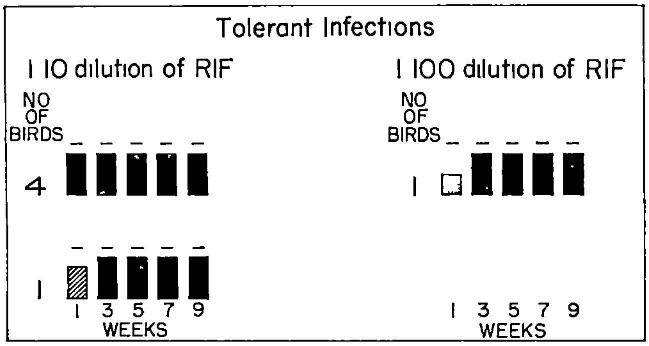

Fig. 2. Eleven-day embryos were infected intravenously with 0.1 ml. of a 1 : 10 or 1 : 100 dilution of RIF stock, and their viræmic and antibody status determined in bimonthly bleedings beginning at 1 week. Antibody detectable in the first bleeding was passively transferred from the hen. Symbols have the same meaning as in Fig. 1.

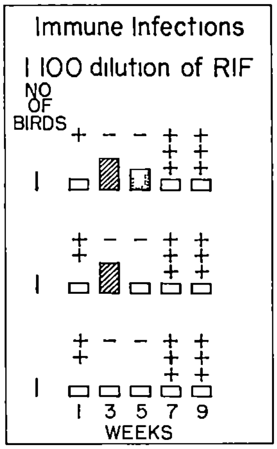

necessary to infect the embryo with high concentrations of virus to ensure tolerant infection. This finding is consistent with the observation that congenital infection, which results in high levels of virus multiplication in the embryo, results in tolerance to RIF, while contact infection, which occurs after hatching, generally elicits antibody production[4].

There are several alternative explanations for the efficacy of early exposure to RIF in establishing a tolerant infection. One possible explanation derives from Burnet's clonal selection hypothesis[5]. On this hypothesis, cells potentially capable of producing antibodies to RIF are eliminated in an unexplained way when the immature animal is exposed to high concentrations of the virus. This would imply that cells with immunological potential in the immature animal interact with antigen in a different way than they do in the mature animal.

Another, and perhaps more plausible, explanation is that cells with immunological potential in animals of any age can be diverted from expressing this potential, if they are exposed to high enough concentrations of antigen for a long enough time. This situation would be similar to the state of immunological paralysis induced in older animals by the inoculation of large amounts of polysaccharides[6] or soluble proteins[7]. Under this hypothesis the failure to establish tolerant RIF infection in older animals could be ascribed to the presence of antibody-producing cells which limit the concentration and persistence of the virus by restricting its spread and speeding its elimination. The ease of establishing tolerant infection in young birds might therefore be due merely to the absence of immunologically mature cells.

Selected data in this article can be used to support or refute either hypothesis, but the second hypothesis seems more attractive at present because it requires fewer assumptions. In any event, the RIF system should be a useful tool in elucidating the mechanism by which tolerance is induced since the concentration of the tolerance-inducing antigen can be accurately determined at all times by virus infectivity measurements, and the antibody response gauged with a high degree of sensitivity and specificity by the virus neutralization test.

Tolerance has been considered here largely as an all-or-none phenomenon. The inadequacy of such treatment is evident from the occurrence of birds classified as partially tolerant. Such birds develop low-level, but persisting viræmias, and sometimes have low concentrations of antibody. The segregation of these birds into a distinct category is probably artificial. There is no assurance that all the birds classified as fully tolerant are equally unreactive to the viral antigen. It can only be said that within a factor of 2 or 3 the level of persisting viræmia is about the same in all 'tolerant' birds and antibody can be detected in none. It is quite possible that there is a continuous spectrum of immunological behaviour running from complete to partial tolerance which escapes our present techniques of measurement.

This investigation was supported by grant No. 4774 from the U.S. Public Health Service and grant No. *E*-82 from the American Cancer Society.

KININASES IN LEUCOCYTES AND OTHER TISSUES

By DR. J. SCHWAB

Lister Institute of Preventive Medicine, London, S.W.1

PLASMA[1], lymph[1] and kidney extracts[2] inactivate bradykinin, but the site of origin and the availability of the inactivator in cells and intercellular fluids, and its relation to inflammatory events, in which both it and bradykinin may play a part, are unknown[3]. Since the onset of the major phase of increased vascular permeability in the early stages of bacterial and other acute inflammation coincides with the onset of frank tissue leucocytosis[4], and the decline of this phase some hours later with massive

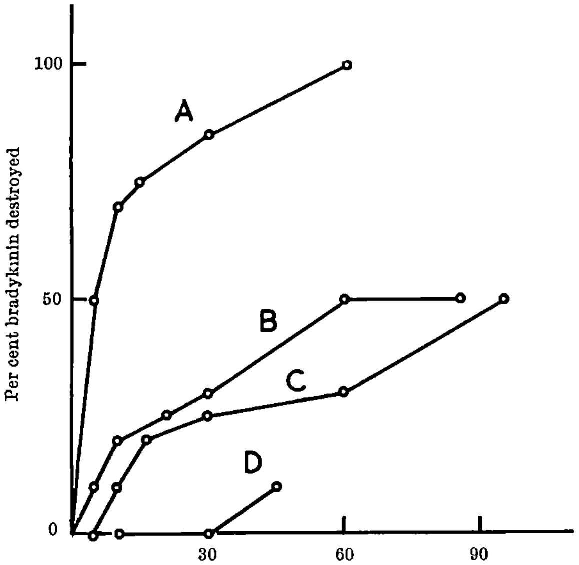

Fig 1

leucocytosis, it was of interest to find whether leucocytes produced either a bradykinin-like permeability factor or an inhibitor of such kinins

Leucocytes were collected from the peritoneal cavity of the guinea pig 4 hr after the injection of 25 mgm mussel glycogen in 25 ml 0 85 per cent saline, washed three times with 0 1 *M* phosphate-buffered saline or Tyrode solution at *p*H 7 4 They were disrupted either by 2½ min sonic vibration or by thrice freezing to the temperatures of carbon dioxide snow in ethanol and thawing The permeability effect of extracts and of bradykinin were measured in terms of the diameter of blue lesions in the dorsal skin of the trunk after intracutaneous injection of the material into depilated guinea pigs with pontamine blue in the circulation[5] As with most permeability-increasing substances, bradykinin induced in the skin lesions the diameter of which was proportional to log concentration, thus potency and change in potency could be estimated from three-point dosage–response lines, using concentrations producing lesions from 4 5–9 0 mm in diameter Crude bradykinin was prepared by tryptic digestion of ox serum globulin, and its kinin effect measured on the isolated atropinized guinea pig ileum in Mg-free Tyrode solution in a 10 ml bath at 34°

Permeability effect of leucocytes Three times washed leucocytes up to 15 × 10^6/ml , and disintegrated leucocytes from suspensions containing up to 15 × 10^6/ml had no effect either on vascular permeability or on the guinea pig ileum There is thus no readily available kinin in the cells

Kinin inhibitors in leucocytes Incubation of bradykinin for 1 hr at 34° with intact leucocytes slightly decreased its permeability-increasing potency incubation with extract, both sonic and freeze-thaw, decreased it four-fold An extract of 10 × 10^5 leucocytes/ml is required significantly to decrease the potency of three effective 'blueing' doses of bradykinin Equipotent amounts of histamine, the synthetic amine compound 48/80 or the protease permeability factors of human and guinea pig serum were unaffected by the extract Inhibition is dependent on the time and temperature of incubation, the concentration of bradykinin, and the medium (extracts in phosphate-buffer saline were three times as potent as in Tyrode at the same *p*H)

The ileum-contracting potency of bradykinin decreases in parallel with its permeability effect Fig 1 illustrates the dependence of inhibition of the contractor effect on time (*A*), the partial inactivation of the extract at 56° for 30 min (*B*), the feeble activity of intact leucocytes (*C*), and the very slight activity of the first washings of intact leucocytes after removal from the peritoneal cavity (*D*) The last observation excludes contamination with humoral substances in the exudate—particularly the powerful inhibitor present in plasma—as a source of the inhibitor The extract loses half its potency after 24 hr at − 10° Intact leucocytes held for 2 hr at 37° in Tyrode in siliconized tubes yield on extraction about half the amount of inhibitor obtainable from unheated cells

The extract was unaffected by immediately prior incubation for 60 min at 20° in Tyrode at *p*H 7 4 with 5 × 10^{-4} *M* di-isopropyl-fluorophosphonate, 0 25 mgm /ml soya bean trypsin inhibitor, 5 × 10^{-3} *M* ascorbic acid, 5 × 10^{-3} *M* ethylenediaminetetra-acetate, 20 × 10^{-3} *M* D-L-leucyl-glycyl-glycine, 20 × 10^{-3} *M* D-L-leucyl-glycine, 5 × 10^{-3} *M* iodoacetate, 5 × 10^{-3} *M* indole, and 5 × 10^{-3} *M* reduced glutathione The inhibitor appears to be an enzyme, distinct from trypsin, chymotrypsin, cathepsin *C* and leucine aminopeptidase

Differential counts of cells in guinea pig peritoneal exudates induced in various ways and calculation of the number of cells yielding extract enough to inhibit half a fixed amount of bradykinin (ID_{50} = 50 per cent inhibiting dose) suggest (Table, *a*–*c*) that cells other than granulocytes were the source of the inhibitor, though the suggestion is weakened by the relatively feeble yield from non-granular leucocytes induced by paraffin (*c*) Exudates induced by glycogen in the rabbit (*d*) were similar to those in the guinea pig (*a*)

Table 1

Exudate-inducing agent and period of induction (hr)		No of cells per ml (× 10^{-5}) yielding one ID_{50}		
			Non-granulocytes	
		Total	Per cent	No
(*a*) Glycogen	4	69	6	4 2
	4	52	7	3 5
	96	6 8	89	6 1
(*b*) Bovine albumin (allergic)	4	30	24	7 2
	72	8 2	70	5 7

(*d*) Glycogen (in rabbit)	18	61	10	6 1

The absence of any peculiar association of inhibitor with cells of the lymphoid-macrophage system is also evident from the activity of fresh guinea pig tissues with varying content of lymphoid tissue Extracts were made of guinea pig organs which had been perfused *in situ* with human-albumin-Tyrode solution before excision, rinsed in Tyrode, lightly blotted, weighed emulsified in Tyrode in a blender for 30 sec , thrice frozen and thawed, and centrifuged at 2,000 r p m for 12 min The wet weight in milligrams yielding one ID_{50} were kidney, 0 3, spleen, 0 8, liver, 1 0, thymus, 1 8, lymph nodes, 2 3, and heart muscle 2 5

Inhibitor in plasma and tissue fluids Guinea-pig plasma is particularly rich in inhibitor The ID_{50} of fresh citrated plasma in five guinea pigs averaged 5 8 × 10^{-4} ml Inhibitor also appears to be available in the intercellular fluid On intercellular perfusion[6], a strip of skin 30 × 15 mm yields most of its inhibitor in the first 3 ml. of perfusate, and in each of the five guinea pigs, the ID_{50} of this 3 ml. sample was consistently about one-fiftieth of that in the plasma—the average ID_{50} being $2{\cdot}7 \times 10^{-2}$ ml.—suggesting that the intercellular inhibitor originates in the blood.

Inhibitor in infected animals. Plasma and intercellular inhibitor are affected by bacterial infection. In guinea pigs with a single *Staph. aureus* lesion in the skin, 8 mm. in diameter and 24 hr. old, the titre of inhibitor in plasma and in perfusates of unaffected skin of the opposite flank was twice that of uninfected animals. This infection is local and regressive; in guinea pigs with a progressive infection, on the fifth day of a febrile, Group C streptococcal septicæmia, the titre in both plasma and skin perfusate was only half that of uninfected animals.

In summary, leucocytes contain a bradykininase-like substance which could be available for the destruction of kinins that might be formed in inflamed tissues. There is as yet little evidence that vaso-active kinins of this type are so formed; but the observation that kininases of plasma and intercellular fluids are increased in a non-progressive, and decreased in a progressive, bacterial infection is compatible with, though by no means indicative of, changes in a kinin-kininase system during infective inflammation.

ROLE OF THE THYMUS IN NEONATAL LIFE

By Dr. DELPHINE M. V. PARROTT and Dr. JUNE EAST

Imperial Cancer Research Fund, London, N.W.7

PRESENT work indicates that the thymus plays an important part in the development of immune response in embryonic and neonatal life. For example, Kalmutz[1] found that the embryo opossum was able to react against foreign antigens as soon as the thymus was functional and before the spleen or lymph nodes became active. It has also been shown that thymectomy performed within 24 hr. of birth impairs the immune response of mice and rats to skin homografts[2-4] and to grafts of foreign cells[5]. In addition, Parrott[5] reported that mice thymectomized at birth died prematurely with wasting symptoms, and it is this aspect of the problem that we have now studied in greater detail.

Mortality of thymectomized mice (Table 1). Most of the *C3H/Bi* and *AKR* mice thymectomized during the first week of life using anæsthesia produced by cooling[6] grew normally until they were 4 weeks old, but those thymectomized within 24 hr. of birth died before the age of 3 months with severe wasting symptoms. The timing of the operation is obviously important because fewer animals died when thymectomy was delayed for 24–36 or 48–72 hr. and these deaths occurred over a long period of time. None of the mice thymectomized at 3–7 days has yet died, and they are now 8–9 months old and 56 animals sham-operated within 48 hr. of birth lived their normal life-span.

C57BL mice thymectomized on the day of birth died precipitately and at an early age. However, with one exception, outbred *TO* mice survived the operation without any apparent ill-effects. This may be attributable to the greater maturity of the thymus at birth and in fact 2/6 *TO* mice thymectomized immediately after delivery by Cæsarean section on the eighteenth day of gestation have already died with wasting symptoms at 8 and 11 weeks of age.

Table 1. MORTALITY OF MICE THYMECTOMIZED WITHIN 3 DAYS OF BIRTH

Strain	Age at thymectomy (hr.)	Mortality	Mean age at death and range (days)
C3H/Bi	< 24	17/17	45 (31–55)
	24–36	10/17	66 (34–169)
	48–72	5/15	141 (99–252)
AKR	< 24	12/12	38 (21–83)
	24–36	7/15	43 (25–75)
	48–72	5/16	83 (51–123)
C57BL	< 24	13/13	34 (30–39)
TO	12–24	1/9	52

Symptoms of wasting disease. Death in thymectomized mice was preceded by a progressive deterioration in their general appearance with stunting or loss of body-weight. Coat condition was poor, the mice were hunched, walked with a curious high-stepping gait and often had diarrhœa.

The most obvious post-mortem features were the thinness of skin and bone and the lack of subcutaneous fat. Liver necroses and hæmorrhage into the gut were frequently seen and the gut wall itself was often thin and flabby. The spleen and lymph nodes varied in size, but the Peyer's patches were always small or atrophic and histological examination showed that the lymphoid follicles of all these tissues were either disorganized or completely absent. The follicles of the lymph nodes were replaced by histiocytes and proliferating reticular tissue and there were sometimes accumulations of pyroninophilic cells in the medullary region. The red pulp of the spleen was increased and its sinuses were packed with polymorphs. Lymphoid depletion was already present in mice killed between 20 and 30 days of age and therefore preceded the onset of physical deterioration.

Changes in the leucocyte population of the circulating blood (Table 2) reflected the histological picture of the lymphoid organs. Lymphopenia was constantly found whether symptoms of wasting were present or not and was frequently accompanied by granulocytosis. Thus, the lymphocyte : polymorph ratio was often completely reversed although the total leucocyte count was unaltered. The association of neutrophilia with lymphopenia is known to occur in other experimental situations[7] but its significance is not understood.

Blood erythrocyte counts were within the normal range[5], although varying degrees of microcytic anæmia

Table 2. Leucocyte Counts of Mice thymectomized at Birth or after Delivery by Cæsarean Section

Strain	No. of mice	Age at thymectomy (hr.)	Age at examination (days)	Leucocyte counts (cells/mm.^{3} ± *S.D.*) Total	Lymphocytes	Polymorphs

	2	C.S. intact	56–77	5,550	4,400	1,070

* Mice thymectomized after delivery by Cæsarean section (C.S.) on the 18th day of gestation. † Symptoms of wasting present.

with anisocytosis and slight hypochromia were seen in smears from mice with wasting symptoms. Preliminary studies of the bone marrow showed an increase in the granulocytic, and sometimes a decrease in the erythropoietic, series of cells.

The possibility that thymectomized mice died from generalized bacterial or viral infections was examined despite the fact that the histological appearance of the lymphoid organs was not consistent with the presence of an infectious agent. Preliminary bacteriological tests and passage experiments were all negative, but it would be unwise to rule out the complication of incidental infection in such debilitated hosts.

Effect of foreign cells on mortality-rate (Table 3). *C3H* mice thymectomized within 24 hr. of birth died at an earlier age and with more acute symptoms of wasting if they were injected intraperitoneally with mature, incompatible, allogeneic cells when 12 days old. Moreover, such treatment increased the mortality in animals thymectomized later than 24 hr. after birth and advanced the time of death. A striking increase in mortality, from 1/9 to 16/16, was also shown by the outbred *TO* mice.

These results confirm the previous report[5] that the immune response of thymectomized mice to foreign cells is impaired. According to Simonsen[8], splenic enlargement can be regarded as an early and reliable index of a host's inability to defend itself against immunologically competent cells and a marked splenomegaly was seen in thymectomized *C3H* mice killed 8 days after the injection of foreign cells (Table 4).

Since the thymus is the main lymphoid tissue present in the fœtal and new-born mouse and its removal within strict time limits at birth causes lymphopenia and lymphoid depletion of the spleen and lymph nodes, we conclude that it is the most important and probably the only, source of lymphocytes during late embryonic and early neonatal life. It may also be responsible for initiating the production of lymphocytes in other lymphoid organs and this initiation could be brought about by a cellular 'seeding-out' process[9,10] or by some humoral mechanism as indicated by Metcalf[11].

The clinical and pathological effects of neonatal thymectomy are remarkably similar to those of runt disease[12] and F_1-hybrid disease[13] in laboratory animals. That is, the symptoms generally associated with a graft-versus-host reaction can apparently be produced by the simple expedient of neonatal thymectomy. It is tempting to assume, therefore, that in runt disease and F_1-hybrid disease the graft is simply the instrument which depletes the host's lymphoid tissue, and that it is this depletion and not the primary immune reaction which is responsible for the associated stunting, cachexia, granulocytosis and possibly the anæmia. This assumption is supported by the fact that foreign cells injected into thymectomized mice accelerated wasting and increased mortality but did not produce any additional or specific symptoms. Presumably such treatment merely exacerbated the already existing lymphoid depletion.

Table 3. Effect of Foreign Cells* on Thymectomized and Intact Mice—Mortality

Strain	Age at thymectomy (hr.)	Mortality	Mean age at death and range (days)
C3H/Bi	< 24	9/9	28 (26–31)
	24–36	10/10	34 (24–43)
	48–72	9/9	44 (31–70)
	Intact	1/25	34
TO	< 24	16/16	37 (23–70)
	Intact	0/24	—

* 2 × 10^7 spleen cells from 2-month-old *C57BL* donors. Recipients injected intraperitoneally at 12–13 days of age.

Table 4. Effect of Foreign Cells* on *C3H* Mice thymectomized within 24 Hr. of Birth—Spleen Weight

Treatment	No. of mice	Wt. spleen (mgm. ± *S.D.*) Absolute	Relative/10 gm. body-wt.
Intact + cells	5	26.4 ± 10.1	37.5 ± 11.9
Thymectomy	6	25.0 ± 10.1	38.0 ± 10.0
Thymectomy + cells	5	80.7 ± 23.5	130.9 ± 22.5

* 2 × 10^7 spleen cells from 2-month-old *C57BL* donors. Recipients injected intraperitoneally at 12–13 days of age and killed 8 days later.

We have shown that thymectomy of mice at birth not only impairs their normal immunological development but also drastically curtails their life span. What is the relation between the immunological role of the thymus and the fatal consequences of its removal? We would suggest that thymocytes or lymphocytes carry out vital functions in addition to those concerned with immune reactions and that the impaired immune response of thymectomized mice is but one symptom of a wider metabolic dysfunction.

We thank Dr. J. Craigie for advice concerning Tyzzer's disease and Dr. S. Gray Anderson of the National Institute for Medical Research for performing bacteriological tests.

EVIDENCE FOR A FUNCTIONAL DISULPHIDE IN PHOTOPHOSPHORYLATION

By Dr J W. NEWTON

Northern Utilization Research and Development Division, Agricultural Research Service, U S Department of Agriculture, Peoria, Illinois

THE investigation reported here was prompted by results of immunochemical studies on chromatophores of photosynthetic bacteria and by the finding that the photochemical apparatus of *Rhodospirillum rubrum* yielded serologically univalent fragments after disulphide scission[1] The presence in these cell particles of a repeating antigenic sub-structure with individual determinant groups spaced between each pair of disulphides was therefore indicated. Production of the univalent sub-units of chromatophores can be brought about by treatment with sulphite, heavy metals under alkaline conditions, mercaptans, or sonic oscillation[2] Since the antigens under consideration are placed in the chromatophore during photosynthetic growth[3], and since the photophosphorylation system appears in the chromatophore under these conditions[4], the possibility of a functional involvement of these structural disulphides in photophosphorylation has been examined

Disulphides are known to undergo interchange reactions as follows

$$R'—S—SR' + R^2—S—SR^2 \rightleftharpoons 2R'—S—SR^2$$

Such a reaction was studied by Ryle and Sanger with model disulphides[5] They showed that the equilibrium under physiological conditions could be forced to the right either by raising the *p*H or by adding a catalytic amount of a thiol At neutral *p*H and with no thiol added, this interchange is slow

If we designate the photochemical apparatus as *ch*—S—S—*ch*, where *ch* stands for a chromatophore sub-unit and *R*—S—S—*R* is an added disulphide, a reaction of the following type can be envisaged

$$ch—S—S—ch + R—S—S—R \overset{(OH)^-(SH)^-}{\rightleftharpoons} 2ch—S—S—R$$

Such a reaction could lead to the insertion of any chosen half disulphide into the chromatophore substructure The physiological consequences of such a situation have recently been examined

Chromatophores were prepared from *Rhodospirillum rubrum* and assayed for photosynthetic phosphorylation by the spectrophotometric method of Frenkel[6] The water-soluble, aromatic disulphide 5,5′-dithiobis-(2-nitrobenzoic acid) (DTNB) was prepared by the method of Ellman[7] Chromatophore preparations having an optical density of about 10 at 800 mμ were pre-incubated for 24 hr in glycyl–glycine buffers at 2° C with 10^{-4} *M* DTNB and other additions Aliquots of the pre-incubated solutions were then added to the phosphorylation test mixture and incubated in light at 25° C for 10–15 min along with dark controls, and the rate of formation of adenosine triphosphate was measured Table 1 shows the results of pre-incubation of chromatophores with 10^{-4} *M* DTNB in the fully reduced and oxidized form, as well as in the presence of a catalytic amount of a thiol at *p*H 8. Although there is inhibition of photophosphorylation either by oxidized DTNB or by excess reducing agents, the most potent inhibition occurs when DTNB is combined with a catalytic amount of thiol, as expected if the inhibition were due to disulphide exchange Either cysteine or sodium monosulphide can be used as catalyst Photophosphorylation was also inhibited by sulphite pre-incubation at relatively high *p*H and by arsenite Inhibition by sulphite was greatest under conditions that produce univalent fragments from chromatophores[2]

Table 1 EFFECT OF DTNB-THIOL PRE-INCUBATION ON PHOTOPHOSPHORYLATION

Pre-incubation mixture	ATP in light mμmoles 15 min
DTNB 10^{-4} *M*	13
DTNB 10^{-4} *M*, Na_2S 10^{-3} *M*	18
DTNB 10^{-4} *M*, Na_2S 10^{-4} *M*	24
DTNB 10^{-4} *M*, Na_2S 10^{-5} *M*	0
H_2S 10^{-3} *M*	15
H_2S 10^{-4} *M*	15
H_2S 10^{-5} *M*	28
No addition	32

Rhodospirillum rubrum chromatophores Pre-incubated at *p*H 8, 2° C , 24 hr at a concentration D_{880} = 10 7 (5 × 10^{-5} *M* chromatophore disulphide) and assayed after 1 10 dilution of pre-incubation mixture in 0 1 *M* glycylglycine *p*H 8 0 containing phosphorylation test mixture

Table 2 EFFECT OF DTNB-THIOL PRE-INCUBATION ON ENZYMES OF CHROMATOPHORES

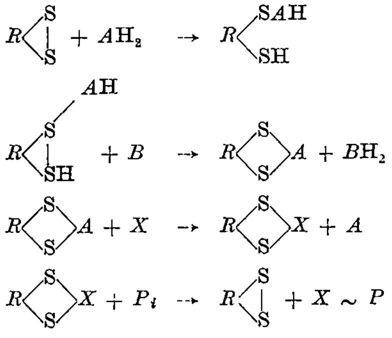
Pre-incubation mixture	Succinic dehydrogenase	Cytochrome photo-oxidase	DPNH-diaphorase
DTNB 10^{-4} *M*	7 0	10 4	6 0
DTNB 10^{-4} *M*, cysteine 10^{-5}	6 9	8 5	5 0
Cysteine, 10^{-5} *M*	10 0	9 8	6 5
No addition	7 0	8 9	6 5

All data are mμmoles acceptor reduced in 5 min by chromatophores (D_{880} = 0 87) after 24 hr pre-incubation at 2° C

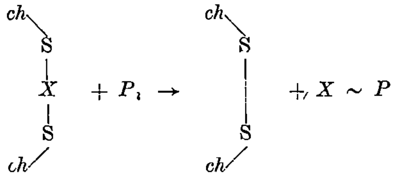
DTNB at 10^{-4} *M* inhibited crystalline rabbit-muscle lactic dehydrogenase and yeast alcohol dehydrogenase approximately 50 per cent, but inhibition was decreased by catalytic amounts of thiols, as expected if the inhibition were a result of oxidation of the thiol groups known to be functional on these enzymes Inhibition of these enzymes was immediate and did not require the prolonged alkaline pre-incubation necessary with chromatophores, which also suggested that the mechanism of inhibition was different

There is a number of reasons for believing that chromatophore inhibition by this means is analogous to uncoupling The DTNB-thiol combination has little or no effect on other enzymatic electron transport reactions of chromatophores, succinic dehydrogenase, cytochrome photo-oxidase or the chromatophore diaphorases (Table 2) The stimulation of mitochondrial ATPase, related to the uncoupling process of mammalian oxidative phosphorylation, is brought about in mitochondrial preparations by precisely the same methods, for example, treatment with heavy metals, sonic oscillation, sulphite or thiols, used to produce univalent chromatophore fragments[8,9] Furthermore, Petrack and Lipmann have recently found that a light-induced ATPase can be unmasked in photophosphorylating preparations treated with very high concentrations of thiols[10]

Fluharty and Sanadi have proposed a mechanism for oxidative phosphorylation that involves interconversion of a vicinal dithiol-disulphide as a primary energy trapping system[11]



Their proposal was based on the uncoupling action of a mixture of 2,3-dimercaptopropanol and arsenite on oxidative phosphorylation Fluharty and Sanadi have left open the question of whether R in their equations is either a small-molecular-weight disulphide or a protein, or whether it is two closely juxtaposed protein chains Any of these possibilities would be consistent with their data The present work supports the Fluharty–Sanadi mechanism and extends it to include photophosphorylation and to the possibility that, since the chromatophore fragments involved are serologically univalent, R in the equations is indeed different protein chains separated by interchain disulphides



It is proposed that separation of these univalent chains constitutes the physical basis of uncoupling, both in chromatophores and in mitochondria

DISCRETE DISTRIBUTIONS OF GENERATION-RATE

By Dr HERBERT E. KUBITSCHEK

Division of Biological and Medical Research, Argonne National Laboratory, Argonne, Illinois

GENERATION-rate (the reciprocal of generation time) appears to be distributed normally for widely different kinds of cells in balanced growth[1] This interpretation is based on measurements of generation times of a bacterium[1], and on data taken from the literature for yeast[2], a protozoan[3], and a strain of human tissue culture[4] When the coefficient of variation of generation-rate is calculated for each of these distributions, a striking relationship emerges these values fall into two rather narrow classes Thus it appears that the coefficient of variation, $C V$, for cell cultures in balanced growth might be limited to certain discrete values

The conditions necessary to obtain valid distributions of generation-rate and generation time have been described[1,5] Several investigations reported in the literature were discarded because they failed to satisfy one or more of these conditions (1) cultures were not in balanced growth, (2) results were presented as an integration of data from sub-cultures with different mean rates of division, whether or not in balanced growth, (3) the data are biased by the recording method, with selection against large values of generation time This kind of selection, first described by Powell[5], occurs when divisions are recorded during a definite interval and all these are used to determine the distribution As the end of the interval is approached, newly divided cells must have shorter and shorter generation times for their division to be recorded in turn Thus the distribution is biased toward shorter generation times This bias may be removed, as Powell pointed out, by measuring the same number of generations in every line of descent from the original ancestor

The same kind of selection also occurs even when the generation times of sister pairs are recorded for a definite interval Some pairs must be discarded because one or both cells fail to divide by the end of the record Thus distributions based on data of this sort again exclude an unduly large fraction of cells with long generation times Since generation time distributions are skewed to the right, this bias can make the distribution appear falsely normal This bias can be made negligible by discarding divisions of all daughter cells for parents born within two mean generation times ($2G$) of the end of the recording interval Alternatively, one can decide to wait for all daughter divisions up to a time at least as long as $2G$ If distributions are found with greater values of $C V$ than those reported here, then the period $2G$ must be appropriately extended

Table 1 COEFFICIENTS OF VARIATION OF CELL GENERATION-RATE

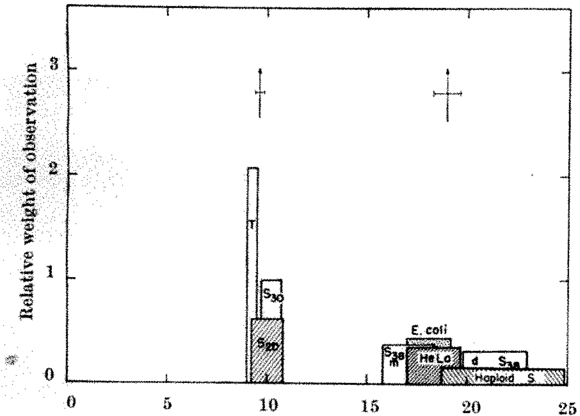

Fig. 1. The grouping of values of *CV* for cultures in balanced growth

Abbreviations: *T*, *Tetrahymena*; *S*, diploid *Saccharomyces*; *Haploid S*, haploid *Saccharomyces*; *m*, mother cells; *d*, daughter cells; a numerical subscript indicates temperature. The rectangles are centred on the value for *CV*, are of width 2 (*S.E.*), and have unit area. The arrows indicate the mean of each group, and the cross-bars indicate the standard error of the mean

The grouping of the values of *CV* for extremely different kinds of cells is evident from Table 1. This table also gives the number of measurements *N* of cell generation times and the standard error, *S.E.*, estimated from $S.E. \simeq CV/\sqrt{2N}$. Within each group the values of *CV* do not differ significantly from one another. This result is shown graphically in Fig. 1. It is quite possible that only two values of *CV* were observed.

These results were unexpected, and their meaning is still uncertain. Nevertheless, if they continue to be supported they must bear significantly on the nature of the control of cell division. They cannot be due simply to a common increase in the value of *CV* at temperatures of 37° C. and above, since the larger value of *CV* was also observed with haploid yeast at 30° C. However, on the basis of the response of diploid yeast, for which division is more variable at 38° C. than at 30° C. or 20° C., increased variability might be ascribed to a temperature-dependent loss or impairment of a control mechanism of cell division. Cytological evidence for the loss of control at 38° C., given by Burns[2], is the failure of mother and daughter cells to bud simultaneously at this temperature.

These findings suggest that very similar, perhaps identical, primary mechanisms control division in widely different kinds of cells. This similarity implies control at the molecular level. Furthermore, the close agreement between the distributions for haploid yeast at 30° C. and diploid yeast at 38° C. shows that although this control might be genetic, it does not depend on the number of chromosomes, and therefore, on gene number or the total content of deoxyribonucleic acid within the cell.

This work was performed under the auspices of the U.S. Atomic Energy Commission.

OSSAL LESIONS INDUCED BY ENCEPHALITIS VIRUSES IN MICE

By Dr. JANINA MARKOWA and Dr. ALFRED MAREK

Second and Third Surgical Clinics of the Cracow Academy of Medicine, and Rickettsia and Virus Department of the Vaccine and Serum Laboratory, Cracow, Poland

A CASE of non-bacterial osteitis of the entire femur in the course of a neuro-infection[1] prompted us to examine the viral lesions of bones.

Viruses of tick-borne encephalitis (strains S_{47}, K_{24} and L_{61})[2-4], and Western equine encephalitis were used in the experiments. Young, genetically pure-line white mice weighing 15 gm. were inoculated intra-ossally. Virus suspensions were prepared according to classical methods after controlling the virulence of the strains. Before each series of inoculations the purity of the virus strain was checked by biological methods. Mice injected intra-ossally with suspensions of healthy mouse brains without viruses served as controls. Bacterial sterility of the suspensions was checked on various culture media. Groups of mice infected with viruses, as well as controls, were anæsthetized at various intervals after inoculation and studied roentgenologically and histologically. (The material was decalcified with 6 per cent nitric acid, fixed in paraffin, and stained with hæmatoxylin–eosin and trichrome.) Table 1 shows the numbers of inoculated mice and the dosage of the different virus strains.

The suspensions used for the inoculations were free from bacterial contamination. Mice of the control groups remained healthy and did not develop any roentgenological or histological changes.

In all the mice infected with viruses histological lesions were found, and in some cases, depending on the duration of the disease, also morbid symptoms and roentgenographic changes (Fig. 1).

An evaluation of the histological lesions showed that two types of pathological process could be distinguished, which were found to be related to the infecting viral strain: (1) lesions beginning as œdema of the bone marrow (encountered in mice infected with the L_{61} and Western equine encephalitis virus, and in part of the mice infected with the S_{47} strain); (2) lesions beginning with extravasation of blood into the bone marrow (in mice infected with the K_{24}, and part of the mice infected with the S_{47} virus).

In the course of changes beginning with œdema of the bone marrow, already after 24 hr. a large amount of amorphous fluid was found in the marrow

Table 1

Kind of strains	General No. of infected mice	No. of intra-ossally infected mice	Intra-ossal doses (ml.)	Time of death (days)
S_{47}	98	38	0·03	46
K_{24}	57	35	0·015	23
L_{61}	62	35	0·015	40
W.E.E.	65	30	0·015	12
Control suspensions	100	65	0·015 0·03	—
Together	382	203

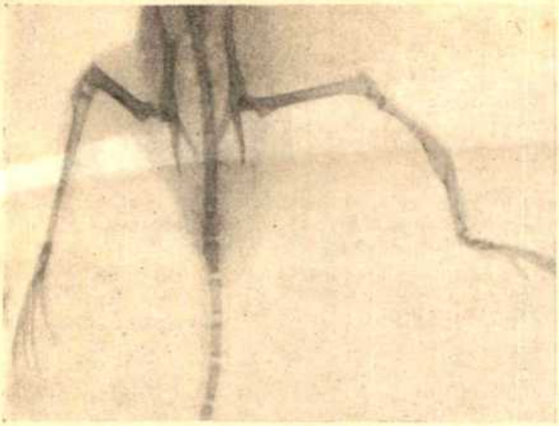

Fig. 1. Dilation of the upper half of the shaft of the tibia on the tenth day of illness

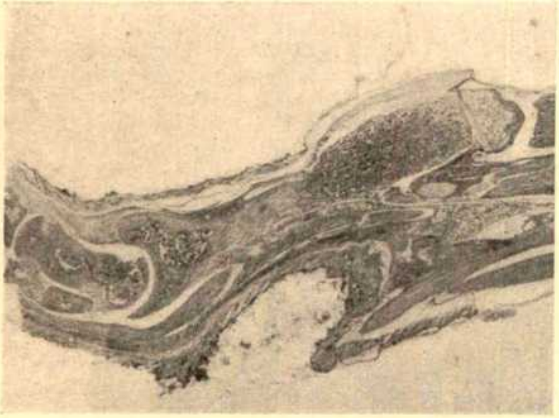

Fig. 2. Shaft of tibia dilated in the proximal half. The œdematous medullary tissue begins to proliferate and push out the rarefied walls of compact bony tissue

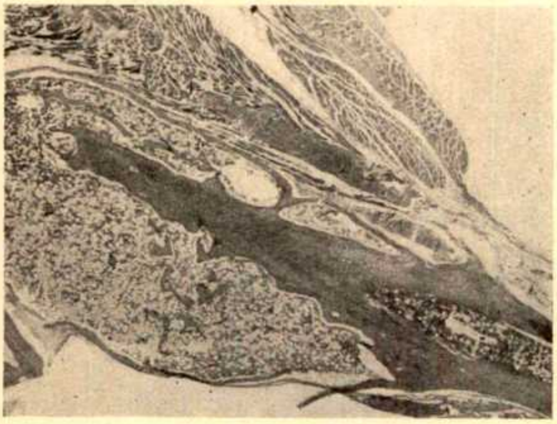

Fig. 3. Longitudinally detached outer lamellæ from the tibial shaft close the proliferating marrow. Lamellæ lying loose here and there in the region of the extra marrow cavity proliferating medullary tissue

cavity, increasing during 3 days and resulting in filling the nutrient and Volkmann canals. The bony tissue displayed necrotic alterations with disintegration. The compact bones disintegrated longitudinally, undergoing a kind of destratification, while the spongy bones showed chaotic decomposition. At the same time œdematous fluid as well as marrow cells were observed outside the marrow cavity, and sometimes even in the interfascial spaces in muscles. After 6–8 days the bone marrow showed signs of proliferation, undergoing partial or complete fatty degeneration (Fig. 2). Proliferating marrow tissue was often seen lying outside the marrow cavity or markedly distending the necrotically altered bone of the shafts (Fig. 3). At this time we also observed defects in the directional columns in the growth cartilages and degenerative changes of the chondroblasts. The articular cartilages showed gradual desquamation, and the bony covering of the epiphyses fissures with marrow cells lying in them. The latter were also present in the articular cavities, which were filled with more or less proliferative connective or fatty tissue.

Osteogenesis was observed after 9–10 days, both in the necrotically altered bones and surrounding them, and also on a substrate of muscle tissue in places containing large accumulations of small mononuclear and plasma cells. The osteogenetic processes took the form of cartilaginous metaplasia (Fig. 4). Small islands of cartilage were found in the destroyed bone, and the bone was surrounded by a cartilaginous and bony sleeve, usually enclosing about one-third of the length of the shaft (Fig. 5).

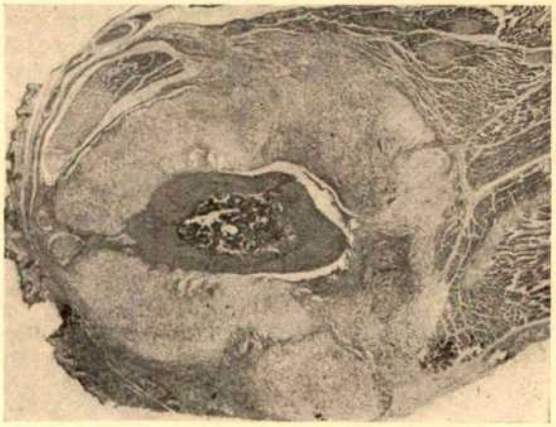

Fig. 4. Transverse section through the shaft of the tibia. A dense small-cell infiltration surrounded by the extended detached external periosteum. Chondromatous metaplasia has already begun

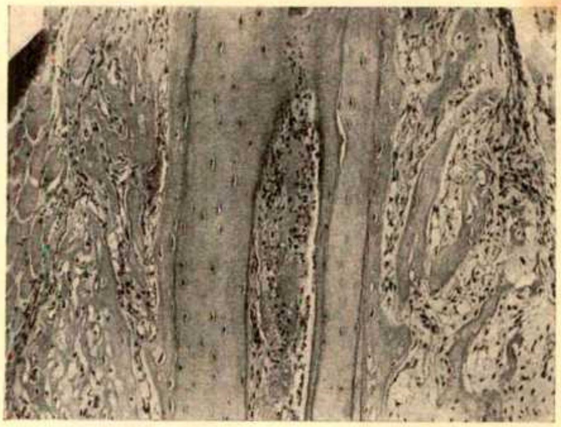

Fig. 5. Near the shaft, typical oval formations of small cells, of considerable dimensions and with well-marked boundaries, undergoing chondromatous metaphasia. There are already freshly formed paraskeletal trabeculæ. × c. 23)

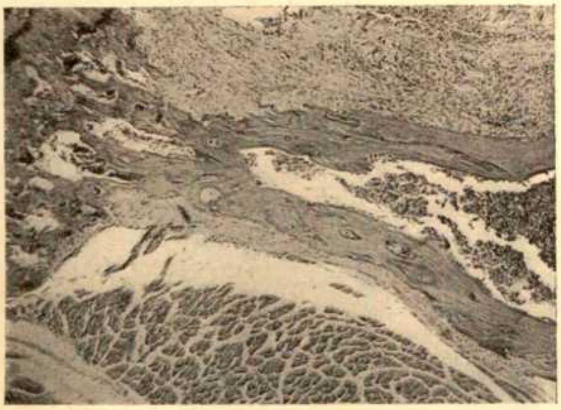

Fig. 6. Marked defects in the bony structure in the upper tibial paraepiphysis. Connective tissue with infiltrations has penetrated into the interior of the necrotically changed bone. The outer edges of the bone are irregular and ragged. (× *c.* 23)

A hæmorrhagic type of extravasation of blood in the bone marrow was noted, presented as massive hæmorrhage. At the same time the external surface of the shaft displayed small penetrating erosions filled with mononuclear cells. After 6–8 days the erosions narrowed the shaft to a quarter of its width, and lymphoid connective tissue was found growing into them (Fig. 6). Proliferation of connective tissue was also observed in the intertrabecular spaces near the epiphyses. In the remaining part of the shafts cavitary cribriform degeneration of the bone tissue took place, giving rise to a moth-eaten appearance. In mice infected with the K_{24} strain the bone marrow also showed proliferation developing similarly to the œdematous form. On the other hand, in mice infected with the S_{47} strain proliferative changes in the bone marrow or lesions of the growth cartilage were not observed. Osteogenetic processes were manifested by cartilaginous metaplasia, always internal or paraskeletal, but never outside the skeleton. Paraskeletal osteogenesis was characterized by formation of bony trabeculæ hanging downward from the bones in conformity with the weight of the extremity, in the form of stalactites.

On the basis of biological investigations carried out during the experiments, living Western equine encephalitis and S_{47} viruses were found in lethal doses in the bones as well as in the brains of the mice.

This summary of results points to the need for comprehensive investigations of the viral pathology of bones and joints. It may be supposed that the still unknown ætiology of many diseases of the skeletal system in man may be cleared up in this way.

OCCURRENCE OF TWO PLASMA ALBUMINS IN THE DOMESTIC FOWL

By Dr. W. M. McINDOE

Agricultural Research Council, Poultry Research Centre, Edinburgh, 9

DURING an investigation of the water-soluble proteins of hen egg yolk by starch-gel electrophoresis, involving a comparison of these with the plasma proteins of laying hens, it became evident that the plasma of some hens contained what appeared to be two albumins present in approximately equal concentrations. Evidence has been obtained that both protein components are albumins, that they consistently occur singly or together in the plasma of different individuals, and that their distribution in a population is under genetical control.

Smithies's[1] method of starch-gel electrophoresis was utilized. Using the continuous and discontinuous buffer systems (pH 8·6) of Smithies[1] and of Poulik[2] heterogeneity of the plasma albumin of the fowl could not be detected. However, at acid pH values heterogeneity of the plasma albumin was indicated. Most of the electrophoresis was carried out at pH 5·4 using a discontinuous buffer system (gel; 0·005 *M* sodium hydroxide, 0·00365 *M* succinic acid: electrode compartments; 0·112 *M* *tris* 0·050 *M* citric acid). A continuous system was also used, the gel buffer then being 0·0112 *M* *tris*, 0·0050 *M* citric acid. Gels were stained in 0·05 per cent nigrosine for 30–50 min. Improved resolution of the presumed albumin bands was obtained if the plasma was diluted with water to give dilutions of 1 in 3 to 1 in 6.

It soon became evident that the hen plasmas were of three types (Fig. 1). In two of the types only one albumin band was apparent, accompanied by a minor component travelling the same distance ahead of the

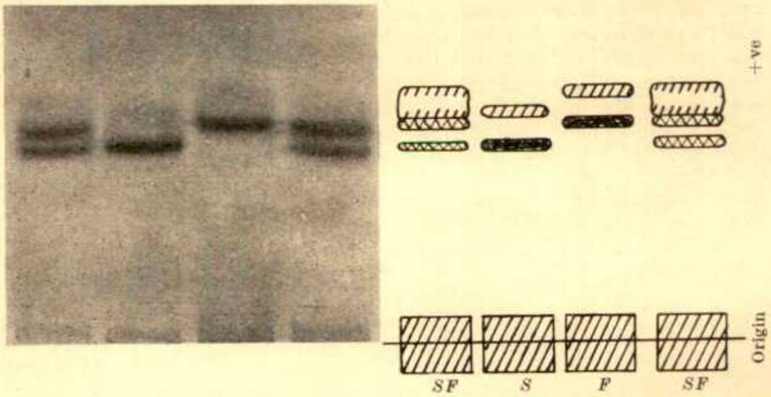

Fig. 1. Starch-gel electrophoretogram of plasma albumin types. Plasma diluted 1 in 4 in each case

albumin in each case. These two types could be distinguished by the rates at which the albumins and minor components migrated, and are designated *S* (slow) and *F* (fast). The third type of plasma contains both albumins, the *F*, and probably also the *S*, minor component, and is designated *SF*. In the discontinuous buffer system, the *S* minor component migrated between the *F* albumin and *F* minor component, but it was not well resolved in the *SF* type plasma. In the continuous buffer the *S* minor component travelled at the same speed as the *F* albumin and could not be detected in the *SF* type in this system. The albumins present in *S* and *F* plasmas occurred in approximately twice the concentration that they did in the *SF* plasma. If the *S* and *F* plasmas were diluted 1 in 6 dilution of the *SF* plasma 1 in 3 gave comparable band intensities. A mixture of *S* and *F* plasmas behaved in the same way as the *SF* plasma on electrophoresis.

Electrophoresis of diluted plasma of each type was carried out in continuous *tris* : citric acid buffer systems at selected *p*H's between 8·6 and 3·5. The single main albumin band evident at *p*H 8·6 gave rise to the components which migrated at different rates at *p*H 5·4. They began to migrate at significantly different rates when the *p*H was less than 8·0 and still had a different mobility at *p*H 4·8, when they were just moving towards the anode. At *p*H's more acid than this, when all the proteins moved towards the cathode, the electrophoresis was not satisfactory.

Both the major and minor *S* and *F* proteins had the solubility characteristics of plasma albumins. All four were soluble in 50 per cent saturated ammonium sulphate and so were present in the conventional albumin fraction of plasma. Mammalian plasma albumins have been shown to be soluble in ethanol after the plasma proteins have been precipitated with trichloroacetic acid[3-5]. Hen plasma was treated similarly and the acid ethanol supernatant examined electrophoretically at *p*H 5·4 after dialysis. Both *S* and *F* major and minor components were soluble in the ethanol and migrated with unaltered mobility.

These results, though based on limited criteria, leave little doubt that the major *S* and *F* components at least are plasma albumins. Evidence is presented below that they are genetic variants.

Genetical relationship of the albumins. Individual hens from five of the Poultry Research Centre's inbred lines of Brown Leghorns and from two of the Reaseheath highly inbred lines of White Leghorns and Rhode Island Reds were examined and typed *S*, *F* or *SF*. Most of the birds were sampled at least twice and two were examined six times, and a consistent pattern was obtained in each case. The results are summarized in Table 1. Although the number of birds examined from each line was small it is evident that two of the lines (*B* and *R*) are markedly heterogeneous, and the *L* and *S* lines are possibly homogeneous. The highly inbred White Leghorns and Rhode Island Reds also seem to be homogeneous. These results point to a genetical basis for the distribution of the plasma albumins in the individuals examined.

Table 1. DISTRIBUTION OF PLASMA ALBUMINS IN HENS OF DIFFERENT BREEDS AND LINES

Breed	Coefficient of inbreeding (per cent)	Type and No. of hens			No. of parents		No. of mating pairs
		S	*SF*	*F*	Dams	Sires	
Brown Leghorn							
1. *B* line	31	2	11	8	16	9	16
2. *I* ,,	46	13	1	0	11	4	11
3. *L* ,,	64	11	0	0	5	2	6
4. *R* ,,	74	4	8	4	7	2	7
5. *S* ,,	79	0	0	6	5	4	6
White Leghorn							
CH line	99·62	17	0	0	10	3	10
Rhode Island Red							
Q line	92·55	7	0	0	4	3	4

It was not possible to type the parents of the birds cited in Table 1, and in order to investigate the possible genetical relationship between the plasma albumins, a number of offspring from four types of matings was examined after the determination of the plasma albumin type of the parents. The types of mating involved were *SF* × *SF*, *S* × *F*, *SF* × *S* and *S* × *S*. The results are summarized in Table 2, and are consistent with a simple Mendelian inheritance of the two albumins and the two minor components. In none of the groups examined was the frequency of the three types significantly different from that to be expected.

Table 2. DISTRIBUTION OF PLASMA ALBUMINS IN FAMILIES OF BROWN LEGHORNS

Dams		Sire	Type and No. of offspring		
No.	Type	Type	*S*	*SF*	*F*
3	*SF*	*SF*	1	12	3
3	*S*	*F*	0	13	0
3	*SF*	*S*	7	3	0
2	*S*	*S*	13	0	0

This genetical relationship between the two plasma albumins implies a probable chemical similarity. Although an investigation of the structure of these proteins has not been carried out, the fact that they migrate at different rates at *p*H's below 8·0 and at the same rate at *p*H's above 8·0 suggests that a histidine residue may be involved in the difference between them. This also applies to the minor components and further indicates a genetical, and possibly a structural, relationship between the albumins and their minor partners.

In several other instances more than one protein in a presumed homozygote appear to be under the same genetical control, that is, the β-globulins of cattle[6-9], sheep[7,10] and pigs[11], the transferrins of mice[12,13] and the ovalbumins of hen egg-white[14]. Genetical control in these systems has been ascribed to one allele. However, since information on the structure of these proteins is lacking and our knowledge of the biosynthesis of polypeptide chains and complex proteins is limited, the precise nature of the genetical mechanism involved remains in doubt.

The only other plasma albumin difference recorded in the literature, so far as is known, is the occurrence in man of two plasma albumins in some of the members of a few families in Europe and the United States[15-17]. A simple Mendelian inheritance is suggested to explain this, but one of the homozygotes has not been observed.

HÆMOGLOBIN MINORS AS POSSIBLE INTERMEDIATES IN HÆMOGLOBIN SYNTHESIS

By JERRY B LINGREL and HENRY BORSOOK

Division of Biology, California Institute of Technology, Pasadena

THE work reported here began as a search for intermediates in the terminal stages of biosynthesis of hæmoglobin The criterion for an intermediate was that it should have higher initial specific activity than the final product and lose specific activity in a chase experiment Such material has been found among the hæmoglobin minors of rabbit reticulocytes

Reticulocytes prepared from rabbits treated with phenylhydrazine were washed and incubated according to the procedures of Borsook *et al* [1] After incubation the cells were again washed The packed cells were lysed according to the method of Schweet *et al* [2] The 105,000*g* supernatant of the cell lysate was dialysed against the appropriate buffer and chromatographed on either DEAE-cellulose or 'Amberlite *CG*-50'

When washed reticulocytes were incubated with L(1-^{14}C)-leucine for 10 min and the resulting labelled hæmoglobins chromatographed on DEAE-cellulose, the elution pattern and specific activities shown in Fig 1 were obtained The hæmoglobin, as measured at 420 mμ separated into two fractions, designated here as *A* and *C* Fraction *A* (the major component) exhibited a specific activity of approximately 30 c p m /420, while that of fraction *C* (the minor component) was 190 c p m /420

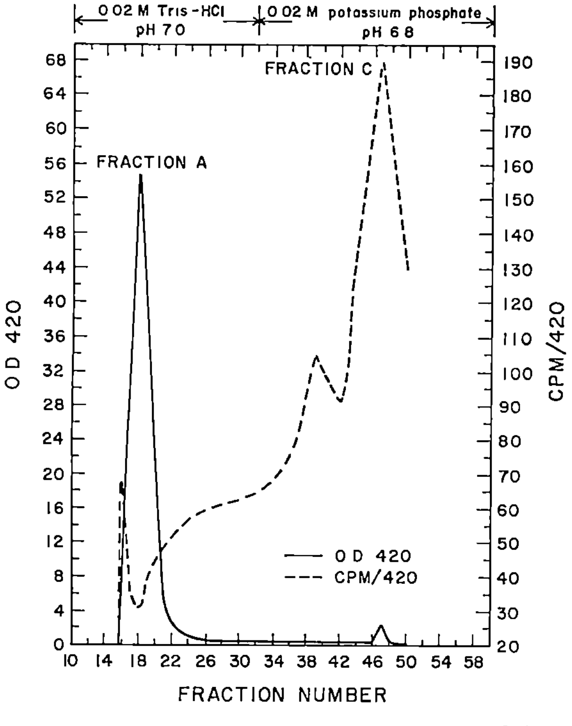

Fig 1 Rabbit reticulocyte hæmoglobin 10 mc incubation with leucine-1-^{14}C Chromatography on DEAE-cellulose

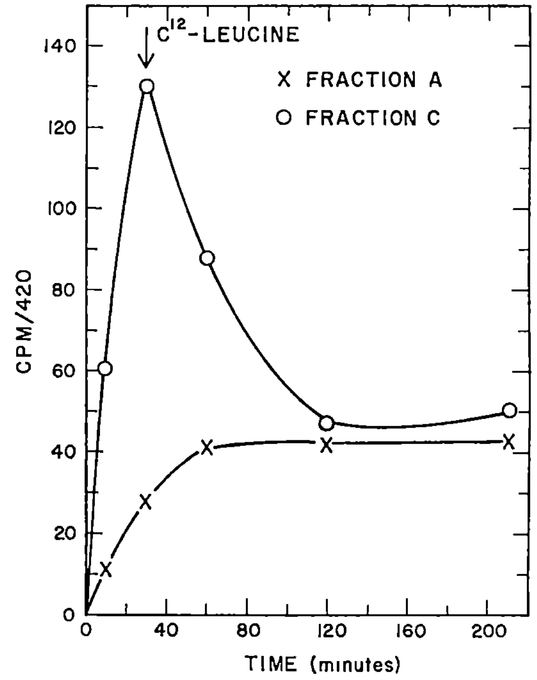

Fig 2 Effect of ^{12}C-leucine chase on incorporation of ^{14}C-leucine into hæmoglobin fractions *A* and *C*

The results of a chase experiment are shown in Fig 2 Reticulocytes were incubated for 30 min in a reaction medium containing labelled leucine, washed with isotonic saline to remove the bulk of the free amino-acid, and re-incubated in the reaction medium containing unlabelled leucine The reticulocytes were sampled at various time-intervals and their hæmoglobin separated into fractions *A* and *C* As shown in Fig 2, the specific activity of fraction *A* increased linearly for the first 30 min, increased further by 35 per cent at the beginning of the chase period and then levelled off The specific activity of fraction *C* increased at nearly a linear rate during the incubation with labelled leucine, attaining a much higher level than fraction *A*, but unlike fraction *A* it lost specific activity during the chase treatment, levelling off at about the specific activity of *A* (the major)

Further analysis of the minor fraction on 'Amberlite *CG*-50' showed that the minor fraction was heterogeneous When fractionation of rabbit hæmoglobin was carried out on 'Amberlite *CG*-50', six components were detected, of which at least three showed a chase effect similar to that shown in

Fig. 2. All the minors behaved on DEAE-cellulose, 'Amberlite *CG*-50' and on starch-block electrophoresis as if they were more acidic than the major. The drop in specific activity during the chase treatment was exhibited not only when the radioactivity was related to hæmoglobin measured at 420 mμ but also at 280 mμ or to dry weight of hæm-free protein.

The possibility that the labile counts in these minors was due to adsorbed leucine was rendered unlikely by the following findings: after treatment with ninhydrin (the leucine was 1-^{14}C), only 0.5 per cent of the radioactivity was recovered in the carbon dioxide; exhaustive dialysis against 0.01 *M* leucine, followed by precipitation with trichloroacetic acid, standing in 1 *N* sodium hydroxide containing 0.01 *M* leucine for 1 hr. at 37° C., re-precipitation with trichloroacetic acid and, finally, extraction with acetone and ether failed to remove counts.

The combined minor fractions, which comprised only 11 per cent of the total hæmoglobin, accounted for 35 per cent of the total counts before the chase treatment. After the chase, there was only 21 per cent of the total counts in the minors. Therefore, 14 per cent of the total counts were labile. This phenomenon clearly is metabolically significant. The results obtained with labelled valine were identical to those with leucine.

The first of these minors to be obtained in sufficient quantity and purity for molecular weight determination was found to have, within experimental error, the same molecular weight as the major.

After adsorbed free leucine had been excluded, there were two obvious explanations for the loss in specific activity of the minors during the chase treatment: (1) dilution of labelled by unlabelled material synthesized during the chase; (2) a simple precursor relationship in which a labelled precursor is replaced by an unlabelled one. Both these explanations appear to be excluded by the following considerations. First, the combined minors comprise 11 per cent of the total hæmoglobin. In order to reduce the specific activity to a half, at least 11 per cent of the total hæmoglobin would have to be synthesized during the chase treatment. In the time interval studied (Fig. 1), there was only a 0.2 per cent increase in total hæmoglobin; this excludes dilution as an explanation. A simple precursor relationship is excluded by the fact that a chase does not reduce the specific activity of any one labile fraction to zero.

One possible explanation for the data is that as hæmoglobin comes off the template it becomes associated with low molecular weight acidic material, which is responsible for the chromatographic and electrophoretic difference of these hæmoglobins from that of the final major or minor forms. This would account for the higher specific activity of the minor fractions. But in order to account for the decrease and final levelling off of their specific activity during the chase, it is necessary to invoke a rapid equilibration of the acidic material with the related pre-existing pool of major and minors; thus a steady-state pool of the more acidic hæmoglobin would exist, and the specific activity of the minor fractions would not drop below that of the major.

Our findings suggest that minors may be classified as either genetic or metabolic. This would help to explain the increasing number of minors which are being found in the fractionation of hæmoglobins.

We thank Dr. Jerome Vinograd for determining the molecular weights. This investigation was supported by grants from the U.S. Public Health Service (*H*-1624), the U.S. Atomic Energy Commission (*AT*(04-3)51) and by a fellowship to one of us (J. B. L.) from the U.S. National Science Foundation.

DISTRIBUTION OF ZINC-65 IN THE WASP, HABROBRACON, AND ITS EFFECTS ON REPRODUCTION

By Prof. DANIEL S. GROSCH

Genetics Department, North Carolina State College, Raleigh, North Carolina

Radiozinc is second only to radiophosphorus as an ecologically troublesome isotope in the vicinity of reactor sites[1]. Following the atomic weapons tests at the Pacific Proving Grounds, zinc-65 was reported in plankton[2], molluscs[3] and fish[4] of the Pacific, and spectrographic analysis of Marshall Islands natives revealed well-defined zinc-65 peaks[5]. Apparently, the isotope persists through food-chains. When zinc reaches mammals an association with sperm develops[6], for which the prostate gland is responsible[7], but nothing has been published about the effect on fertility.

The investigation reported here was performed with insects uniquely suited for single feedings as well as analysis of fecundity and fertility. The wasp, habrobracon (*Bracon hebetor*), features an expansible crop, four identical polytrophic ovarioles, and haploid parthenogenesis. Samples of about 20 adults from Whiting stock No. 33 were fed measured amounts of zinc sulphate labelled with zinc-65 in sucrose water. For feeding, the sulphate must be used instead of the readily available but unpalatable chloride form. Exposure to an external source was accomplished by depositing labelled zinc chloride on planchets used to cap the lucite chambers described previously[8]. In addition, wasps were reared on host caterpillars (*Anagasta kuehniella*) injected with 105 μc. of labelled zinc chloride made up in 10 ml. of insect Ringer solution. However, the procedure was discontinued when 660 eggs transferred to injected hosts yielded only 20 adults. Apparently, chronic exposure during development has more serious consequences than the main experiment with adults reported herein.

The radioactivity of whole animals, body parts and eggs were assessed using a conventional scintillation well counter connected to an integrating decade scaler An automatic sample changer was used for tissue localization studies Eggs were collected daily and their hatchability scored after 48 hr The records obtained for unfertilized eggs from virgin females give total induced lethality, recessive as well as dominant

Egg production consistently lower than control values was obtained after ingestion of four different doses of zinc-65 Daily averages subsequent to a feeding at the highest level (105 μc /ml) is shown in Fig 1 A curve parallel but lower than controls is more typical of metal poisoning than radiation damage[9] A sixth to tenth day valley characteristic of radiation damage was obtained only by chamber exposures to zinc-65 γ-rays at a level (2 85 mc) far above that of any palatable mixture yet devised This result from the highest of a series of six exposures is also shown on Fig 1

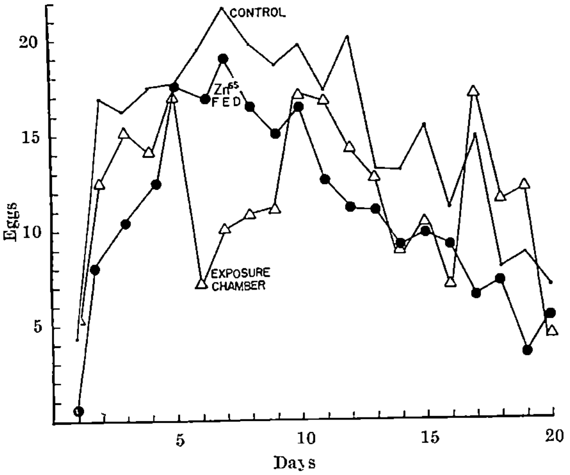

Fig 1 Average number of eggs laid per day by samples of 20 virgin habrobracon Solid circles give results following feedings of zinc sulphate labelled with zinc-65 in sugar mixtures of 105 μc /ml Pre-starvation of these wasps and the sugar-fed controls was at least 96 hr Triangles represent oviposition records of wasps exposed for 96 hr to 2,850 μc of zinc-65 deposited on the metal cap of a lucite exposure chamber

A summary of hatchability for the eggs of Fig 1 is given by Table 1, along with mean life-span The standard errors associated with hatchability range from 5 to 6 except for the third day value of 8 67 for fed zinc-65 Comparison with results from feeding non-radioactive zinc indicates that the decrease in life-span and the inviability of eggs laid late in life may be explained by the metal burden On the other hand, consistently lower hatchability of eggs deposited before senility may be ascribed to radiation damage Most interesting is the exceptionally low hatchability of eggs deposited on the third day, because, as shown in Fig 2, third-day eggs are the most radioactive

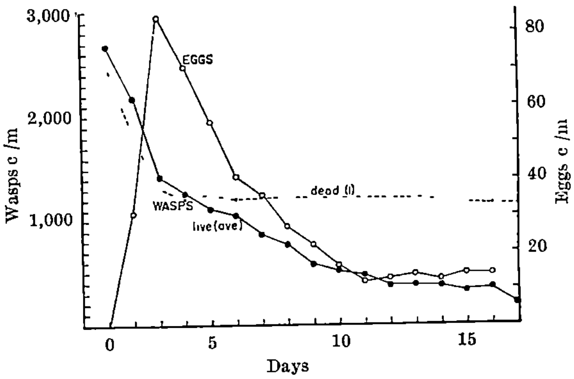

Fig 2 Relative radioactivity of female habrobracon and of eggs laid after ingestion of labelled zinc sulphate in sugar mixture The values are corrected for background but not for physical decay Solid symbols give an average value per wasp based on a sample initially numbering 23. The broken line gives the counts per min of a wasp which died on the fourth day to demonstrate how slight the contribution of physical decay Open circles represent egg radioactivity For convenience, the scale, shown on the right, is calibrated in counts per ten eggs

In addition to depicting the peak in egg radioactivity, Fig 2 also characterizes the decline in radioactivity of ovipositing female wasps The curve shows that the effective half-life for a zinc-65 meal is reached after 2–3 days There is no clear break in the curve, but if one is construed as has been suggested by some ecologists, values later than the third day may indicate the radioactivity of the pool of assimilated zinc-65 Even on this basis the effective half-life would not be more than 7–9 days

In localization studies, samples of 6–8 wasps were killed each day Individuals were counted, transected at the petiole, and then the anteriors and posteriors counted separately The 20 wasps surviving development on radioactive caterpillars showed a relatively homogeneous distribution of zinc-65 with anteriors as radioactive as posteriors A strikingly different pattern of distribution was obtained after adult single feedings Nearly all the radioactivity in the wasp was abdominal, the average rose from 88 to 97 per cent of the total during the first two days During the subsequent week the average abdominal radioactivity dropped to 90 per cent of the total, which held until the fifteenth day Thereafter, higher values became common and by the twentieth day abdominal radioactivity averaged 99 per cent of the total

Anteriorly, muscle and nervous tissue predominate and the digestive tract is represented by only a slender œsophagus In the abdomen, four types of tissue can be separated by dissection digestive tract, fat and urate bodies, gonads and accessory glands, and body wall structures During the first two days, as might be expected, most of the ingested radioisotope was associated with the digestive tract Afterwards the value dropped, but never lower than 50 per cent Counts of the paper disks from the

Table 1 PERCENTAGE OF HATCHABILITY FOR EGGS DEPOSITED DURING DESIGNATED SUCCESSIVE PERIODS
The average life-spans of the ovipositing females are included

Treatment	Days after treatment								Mean life-span (days)

Cytological stage when treated	Oocytes progressing through prophase					Transitional cells	Oogonia	Oogonia (senility)	Somatic tissue

* The level used in exposure chamber, 2 85 mc , is greatly in excess of the level of feeding, 105 μc /ml

bottoms of the dishes containing experimental habrobracon demonstrated that significant amounts of zinc-65 were egested. The fæcal route is well known in rats, where it serves even for loss of injected zinc-65 (ref. 10), but habrobracon, an insect, lacks a pancreas.

No attempt was made to determine whether excretion is localized in the Malpighian tubules or in some part of the hindgut. Another tissue of related function, the urate bodies, was found to contain most of the remaining abdominal radioisotope, 20–30 per cent, exceeded by the ovaries only before the third day. The body-wall, along with the heart, œnocytes and tracheal trunks, had very little radioactivity. In males the pattern was similar except that the reproductive system never became appreciably radioactive. This, plus my previous experience that radiophosphorus is relatively ineffective when fed to adult males[11], led me to emphasize female responses here. Even so, a zinc-65 meal seems ineffectual when compared with the impressive decline in second week oviposition after feeding from a 100 μc mixture of phosphorus-32 (ref. 8). Indeed, the influence on egg production as well as such interrelated phenomena as shortened life and poor hatchability of eggs laid during senility seem due to zinc toxicity.

Radiation from ingested zinc-65 may influence the hatchability of eggs laid during youth and middle age, but except for the low value of the third day, results are not as impressive as after a feeding with phosphorus-32. This may be understandable when we consider that less than 20 per cent of the zinc-65 meal is eliminated via the eggs in contrast to 60 per cent of a phosphorus-32 meal taking the route[12]. Furthermore, the radiations differ. Instead of phosphorus-32 β-particles with a range of millimetres we are now dealing with an isotope from which considerable energy is released as more penetrating electromagnetic radiation attenuated only by metres of tissue. Much of the γ-ray energy is dissipated outside an organism measuring only 0.5 mm × 2 mm., or after incorporation and oviposition outside of the smaller eggs. By the use of simplifying assumptions it can be shown that following an isotope meal the energy delivered to the wasp per disintegration is 20–30 times as great from phosphorus-32 as that delivered from zinc-65.

ŒSTROUS CYCLES IN THE RABBIT *ORYCTOLAGUS CUNICULUS* (L.)

By K. MYERS and W. E. POOLE

Wildlife Survey Section, Commonwealth Scientific and Industrial Research Organization, Canberra

It has long been held that there is no regular œstrous cycle in the rabbit, and that female rabbits remain in a state of œstrus for long periods of time, provided environmental and nutritional conditions are favourable[1–4]. It is also believed that both the domesticated female rabbit and the wild female rabbit[5], given suitable conditions, will accept the buck at any time, although with reduced frequency during pregnancy.

More recently, the occurrence of a cycle of sexual behaviour in confined female wild rabbits was reported[6]. Females became sexually attractive to males at intervals of approximately 7 days (probability of 7-day periodicity < 0.01). The cycle in sexual behaviour has since been correlated with an associated cycle of follicular development, with follicular growth, measured in terms of mean follicular diameter, taking the form of a quadratic regression $y = 0.3794 + 0.1952x - 0.01306x^2$ ($P < 0.05$). Females held separate from males entered into a state of persistent œstrus. The uteri of females developed typical luteal characteristics after a display of strong attraction when mating usually occurred. No females built nests or lactated (Poole, W. E., unpublished results).

In view of this evidence and of the previous findings that the female domestic rabbit has a follicular cycle of about 7 days[7,8] or 7–10 days[9], and of the demonstration of a regular peak in the number of cornified cells in the vaginal smear from unmated does occurring at 4–6 day intervals[10], a reappraisal of the sexual behaviour of female domestic rabbits is clearly necessary.

For the past three months one of us (K. M.) has been observing the behaviour, daily, of 11 female domestic rabbits running with vasectomized males in a ¼-acre enclosure. Two strains of females, lops and cross-bred straight ears, bred and reared at the Institute for Medical and Veterinary Science, Adelaide, are being used. Like their wild counterparts, the domestic females periodically become sexually attractive to the males, but at the shorter intervals of 4–6 days, or multiples thereof ($P < 0.0001$). Vaginal smears taken from the cervical region of the vaginæ of cycling females suggest the occurrence of cyclic changes of epithelial cells. It also seems possible that examination of the ovaries will show a follicular cycle of the same periodicity, thus substantiating the findings of earlier workers[7–10].

It is possible that a shorter cycle exists in domestic rabbits because of the effects of artificial selection during many generations of breeding in captivity

Two of the domestic female rabbits dissected at the height of their sexual attractiveness, and after being subjected to ardent male sexual advances, ovulated without mating Females which mated became pseudopregnant At the end of pseudopregnancy (usually 12 or 18 days) most females dug burrows and covered the entrance with soil Few females built nests or lactated. Two females permitted to mate with fertile males at *post-partum* conceived and carried their fœtuses to full term (litter sizes of 5 and 6) while suckling the first litters

The female wild rabbit and the female domestic rabbit thus appear to be essentially the same animals when placed under similar conditions Earlier observations of persistent œstrus in domesticated female rabbits, usually isolated from males, now fall into better perspective

The occurrence of a regular œstrous cycle in female rabbits appears to be totally dependent on exteroceptive stimuli, of a psychological nature, occasioned by the presence of males and, possibly, other females This is in agreement with the recent suggestion[11] that once the output of pituitary gonadotropin is sufficient to induce follicular maturation there is no sharp division between spontaneous and induced ovulation when exhibited in the same species, the two being regarded as extremes of the same response, determined by the degree of extraneous stimulation As far back as 1935 it was suggested that the regularity or irregularity of œstrous periods in female rabbits depended on the sensitivity of the ovulating mechanism to the stimulus given by the advances of the male[8] The importance of male–female interaction in the œstrous cycle of the mouse has been demonstrated[12,13] The presence of strange males causes the breakdown of corpora lutea in pregnant mice, thus constituting an exteroceptive block to pregnancy[14,15] In like vein it has been shown recently that the smell and sound of rams is sufficient to stimulate œstrus in merino ewes after the spring anœstrus[16]

These findings raise important issues for animal husbandry Domesticated animals like the rabbit have long been the subject of physiological research and an imposing mass of data relating to internal function exists It seems an appropriate time for the naturalist to focus his attention on the ecology of domesticated animals and to study, with the physiologist, the interplay between behavioural stimuli and endocrine response

RESPONSE OF *NEUROSPORA* MUTANTS TO CARBON DIOXIDE

By Dr H P CHARLES

Department of Microbiology, University of Reading

FAIRLEY reported that α-aminobutyrate or threonine would support growth of a *pyrimidine* mutant of *Neurospora* (*pyr*-3, 1298)[1] This observation was made with liquid cultures

Attempts to repeat this observation using solid media were at first unsuccessful The medium of Ryan, Beadle and Tatum[2] was used, with 0 5 per cent sucrose and 1 per cent sorbose Experiment showed that only rare conidia gave rise to colonies on minimal medium supplemented with α-aminobutyrate Even fewer colonies appeared on threonine-supplemented medium Many of these colonies retained the 1298 mutant character on transfer

Eventually it was observed that when α-aminobutyrate Petri dishes were removed from the incubator and left out on the bench many colonies gradually developed This lead to the discovery that all conidia give rise to colonies on α-aminobutyrate or threonine at 20° C , at 26° colonies are infrequent, and at 30° no colonies develop

The mutant is therefore 'temperature-sensitive' when growing on α-aminobutyrate or threonine It is not temperature-sensitive when supplied with an adequate amount of uridine

Arginine (0 5 mgm /l) prevents growth on α-aminobutyrate (AB) or threonine, but has little effect on growth in the presence of uridine Such an effect of arginine has been observed independently by Boyd and Fairley[3]

The next problem considered was why rare conidia were able to grow at 26° C Eventually our attention was directed[4] to a paper by Borek and Waelsch[5], who showed that temperature sensitivity of *Lactobacillus* was attributable to decreasing solubility of carbon dioxide with increasing temperature This led to the discovery that AB or threonine support growth even at 30° if the Petri dishes are placed in a desiccator having 15 per cent of the air replaced by carbon dioxide The mutant does not grow on unsupplemented minimal medium under these conditions

Preliminary auxanographic tests show that many substances support growth of *pyr*-3 (1298) in an atmosphere of 10–15 per cent carbon dioxide, for example, homoserine[6], α-ketobutyrate, glycine, cysteine, serine, lysine, orotate, β-alanine, propionate[6], succinate, formate, thymine, cytosine, dihydrouracil, methionine Among substances failing to support growth are citrate, malate, aspartate and proline

The mutant grows on unsupplemented minimal medium in the presence of 20–30 per cent carbon dioxide Such carbon dioxide effects are not attributable to a simple disturbance of *p*H

It seems likely that the growth in liquid medium observed by Fairley is attributable to accumulation by the conidia of sufficient carbon dioxide to permit a response to AB or threonine Occasional very dense clusters[7] of conidia on solid medium may partly explain the occurrence of rare colonies on AB or threonine at 26° C It is possible that the many substances supporting growth in 15 per cent carbon dioxide do so by acting as sources of extra carbon dioxide, but it is difficult to explain the inactivity of certain metabolites on this basis It should be noted that none of the active substances increases the growth of *arg*-3 (see below)

If Petri dishes are placed in a sealed desiccator (5 litre) containing 100 ml of 25 per cent potassium hydroxide, the mutant fails to grow on AB or threonine even at 20°, but growth on uridine is not prevented Growth of wild-type *Neurospora* is not prevented by deprivation of carbon dioxide in this way

All the carbon dioxide effects already described are prevented by arginine

It seems probable that growth of a uridine mutant of *Escherichia coli*, examined by Rudner and Ryan[8], is explicable in terms of a response to carbon dioxide

Many variants have been isolated from 1298 Some are probably 'suppressed' mutants, because they grow more slowly on minimal medium than does the wild-type, and growth is prevented by arginine[9–11] This sensitivity to arginine suggested that the suppressed mutants are responding to atmospheric carbon dioxide Experiment confirmed that many of the suppressed strains fail to grow in a desiccator containing potassium hydroxide It is of interest that arginine increases the growth of some suppressed strains if uridine is also present

The most reasonable explanation of the response of mutant 1298 to carbon dioxide is that it requires exogenous carbon dioxide for synthesis of uridine It is known that labelled carbon dioxide enters pyrimidines and other cell constituents of *Escherichia*[12], but one would have expected sufficient carbon dioxide to be available from other metabolic processes Presumably carbon dioxide enters the pyrimidines via carbamyl phosphate[13] This also presents difficulties, because carbamyl phosphate is also a precursor of citrulline and arginine[14] If blocked in carbamyl phosphate synthesis the mutant should therefore require citrulline or arginine, as well as uridine

Examination of five *arginine* mutants showed that one of them (*arg*-3, 30300) responded to carbon dioxide Of the mutants tested this was the only one likely to be disturbed in carbamyl phosphate synthesis, in that it was the only one responding to citrulline but not to ornithine This mutant grows slowly on minimal medium, deprivation of carbon dioxide prevents this slow growth

It is therefore necessary to explain the occurrence of *arginine* mutants which do not require uridine, *uridine* mutants which do not require arginine, and the growth of both types of mutants in the presence of carbon dioxide

Possibly the uridine requirement results from an internal inhibition by arginine This is suggested by the sensitivity of 1298 to arginine inhibition We have been unable to show growth promotion by the arginine antagonists lysine and canavanine, but Mitchell[15] reported that two other *pyrimidine* mutants (*pyr-3a*, *pyr-3b*) grew on lysine when ammonia was excluded from the basal medium Further, some lysine mutants (*ly* 3, *ly* 4) accumulate pyrimidines[10] Davis has suggested that *pyr* 3*a* (37301) is actually arginine inhibited, because the presence of a suppressor mutation is correlated with a 97 per cent reduction in ornithine transcarbamylase activity[16]

Conversely, it may be that some *citrulline* mutants actually suffer from inhibition by uridine precursors This is suggested by the fact that the citrulline requirement is not expressed in the presence of a block in pyrimidine metabolism[17]

Numerous interactions between *pyrimidine, lysine* and *arginine* mutants are known A pathway such as that considered here, leading to both an amino-acid and a pyrimidine, might be the subject of complex controlling mechanisms relating amino-acid and nucleic acid metabolism The mutants discussed here may have disturbances in such controlling mechanisms

It is relevant that various morphogenetic effects of carbon dioxide are known, for example, in *Blastocladiella*[18] and *Hydra*[19] It would be of interest to examine the effects of uridine, arginine, etc , on the development of these organisms

Present experiments follow several lines First, the nature of the lesion in 1298 is being investigated Secondly, we are investigating the interactions between *pyrimidine, arginine* and other mutants Thirdly, we are attempting to isolate, by special methods, mutants of *Neurospora, Aspergillus, Escherichia* and *Salmonella* which require carbon dioxide It is probable that such mutants are often eliminated by the usual isolation methods This approach should reveal whether there are *carbon dioxide* mutants having nutritional patterns different from those studied here

Part of this work was carried out during tenure of an Imperial Chemical Industries research fellowship in the Department of Botany, University College, Swansea *Neurospora* stocks were kindly provided by Prof D G Catcheside

CORALS AT THE MOUTH OF THE REWA RIVER, VITI LEVU, FIJI

By DONALD F SQUIRES

Division of Marine Invertebrates, Smithsonian Institution, Washington, D C

TWO significant controls on the development and rate of growth of colonial reef corals and of coral reefs are the salinity of the water and the quantity and texture of sediment being deposited in the reef area Throughout much of the Indo-Pacific region these ecological factors are of little concern for atoll islands are small and low and do not possess stream systems or contribute appreciably to the sediment load being transported across the reef High volcanic islands, on the other hand, often do have significant drainage systems which may carry heavy sediment loads, often with deleterious effects on the reef and the reef community One of the largest of these river systems in the Indo-Pacific is the Rewa, which is about 90 miles long and which drains approximately one-third of the island of Viti Levu, Fiji During February 1959, together with Messrs Rob Wright and E S Corbett of Suva, Fiji, I was able to make a brief traverse of the reefs on the eastern side of Nukulau Island in Rewa Roads Although examination was cursory and the area investigated was quite limited, some of the observations are of interest

The well-developed reef of Viti Levu is conspicuously broken in three areas along the southern shore of the island where the Singatoka, Navua and Rewa Rivers discharge Of these three, the greatest disruption of the reef pattern is caused by the Rewa River The lower portion of the river is occupied by a complex of islands, probably deltaic in origin Discharge of fresh water is diffused through a number of channels as a result of this complex, the main areas of outflow being the Navuloa mouth, the Nasoata mouth and the Nukulau mouth This last named, the largest, discharges across a large area free from coral islands called the Rewa Roads, in which there are channels to the delta with depths to 10 fathoms across the strike of the reef To the west, Rewa Roads is bounded by Nukulau Island and to the east by Taituanga Island A traverse was made from the north-east portion of Nukulau Island around the eastern end of the reef surrounding the island to the reefs on its southern shore

On the inner side of Nukulau Island and within Lauthala Bay corals are rare or absent None was seen during these observations Fish of a variety of types were abundant, and a few calcareous algae were seen on the rock surfaces Much of the rock was covered by a layer of fine silt which adhered to the surface In some instances this layer of silt reached 1 in in thickness Characteristic of the rock on the north-eastern end of Nukulau Island reef was an extensive system of tortuous grooves and channels cut into the rock to a depth of about 15–20 ft below mean tide-level In many places buttresses of rock were undercut and there was considerable evidence of the breaking off of pieces of country rock as a result of solution Channels between buttresses contained rounded rock fragments and dead corals loose on the bottom All rock observed was formed of calcium carbonate

During the period of observation, a falling tide, fresh water flowing outward from the Rewa seemed to be largely confined to the upper 3 ft and was underlain by about a foot of visibly mixing water, in turn underlain by saline water No measurements were made of the salinities, but the upper layer was distinctly fresh to taste, while below a depth of 5 ft, more normal salinites were encountered The upper layer of water was turbid and contained considerable quantities of fine sediment and organic particulate matter, some of which was visible to the naked eye Visibility in the upper layer was greatly restricted In the more saline waters below, visibility increased in direct proportion to the decreased turbidity, very little particulate matter being seen Some epifauna was observed at depths of 15 ft or more, the number of animals apparently increasing with depth

Off the east-north-east portion of the Nukulau reef (station 2, Fig 1), the first corals were observed Individual colonies of *Porites* up to 1 ft in diameter tightly encrusted the rock surface, the thickest portion of the colony being only inches deep These scattered colonies were a bone white in colour, some having grey patches on their surface Many of the colonies were dead, although several were collected which

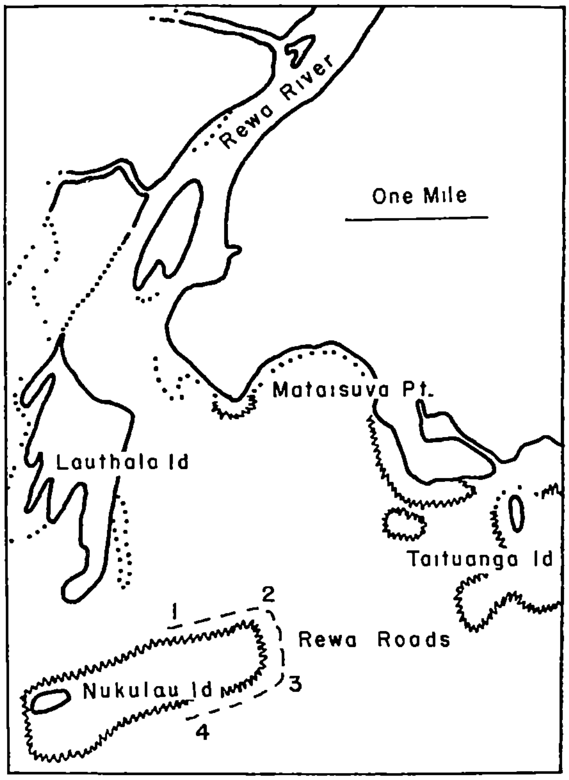

Fig 1 A portion of Viti Levu, Fiji, showing the Rewa River and its relationship to the reef area described Traverse points discussed in the text are numbered 1–4

were in part, at least, alive The colonies were conspicuous through the turbid water as the rock surface is generally a dull brown and is largely devoid of other life Sediment cover on the rock was less than that observed previously Layering of the water was approximately that of the previous description and there was no apparent change in turbidity Most of the coral colonies were found at a depth of about 10 ft Below this depth few corals were seen although alcyonarians (both dead and alive) were noted

Approximately 100 ft farther to the south from the point at which the white corals were seen, similar colonies of *Porites* were found, but which were a bright yellow in colour In general, these colonies were located in a depth-range of 6–30 ft Turbidity decreased, and the water had become better mixed so that downward visibility had greatly increased An interesting feature of these encrusting corals was the severe damage done to the upper surface by intense predation by parrot fish Presumably other fish species known to feed on coral are also responsible for the observed damage, but actual observations of 'grazing' of the coral were limited to the parrot fish Nearly the entire surface of these colonies were deeply grooved in all directions and orientations with the characteristic broad parallel scrape-marks made by these fish

Within a distance of another 100 ft of this point, and in a southern direction, a variety of Faviid corals appeared, but included only small caliced encrusting types Within another 200 ft, that is, within 400 ft of the point at which corals were first observed, a respectable fauna consisting of upwards of 30 species could be found Coral growth then rapidly increased in luxuriousness until the complete reef fauna similar to that found in more normal environments was encountered The coral fauna of the small detached reef patches off the east coast of the Nukulau Reef did not seem to differ in any important respects from that of the main reef to the south of Nukulau, or elsewhere along the southern coast between Nukulau and Suva In this region of rapidly increasing diversity of corals, little of the previously observed effects of the river could be noted Turbidity was not visually noticeable and the waters were well mixed Surge of the breakers on the reef front and of the swell moving up the Rewa channel could be felt Among the corals first to appear were *Archelia* (noted elsewhere on the reefs, generally in shaded areas), meandroid 'brain' corals particularly those with broad calicular vallies, and encrusting forms of *Montipora*

In summary it may be said that

(1) The succession of coral species observed from the central to the outer portion of the western margin of Rewa Roads is that to be predicted from the work of Mayer[1] and Edmondson[2] on the salinity and sediment toleration of various species of coral

(2) Effects of sediment in suspension are mainly in reduction of light penetration restricting the depth of coral growth and may result in the death of symbiotic zooxanthellæ in certain corals

(3) Density layering of waters of differing salinity may impose upward limits of growth on reef corals as well as other stenohaline forms

(4) Reef inhibition adjacent to large rivers is caused in the first instance by deposition of silt, and then by fluctuations in salinity These factors progressively decrease in effectiveness seaward so that a faunal gradient is developed Where swell and breaker action causes complete mixing of waters, flocculation or dispersion of suspended sediment, normal reef conditions may be found

(5) Absence of surface reefs from central Rewa Roads probably results from historical factors and erosion, not from direct inhibition of coral growth

A PHYSICO-CHEMICAL TREATMENT OF TASTE THRESHOLDS

By Prof THOR R RUBIN
Department of Chemistry, The Ohio State University
AND
FRANCES GRIFFIN and Prof ROLAND FISCHER
Research Division, Department of Psychiatry, The Ohio State University, College of Medicine Columbus 10, Ohio

ADSORPTION as a factor in taste perception has been implied by Cameron[1] It has been discussed explicitly by Ferguson[2] and Beidler[3], who expressed the relationship between concentration and taste intensity through Freundlich- or Langmuir-type equations Beidler recently proposed a Lineweaver–Burk type equation for the possibility of a theoretical prediction of "the intensity of sensation reported by a human subject to certain mixtures of two taste substances of similar taste quality"[4] Using quinine and 6-*n*-propylthiouracil, among other drugs, it was found that high affinity (sorption) of a compound for a protein model receptor could be related to the physiological activity[5], in this case, to the low taste threshold[6,7] of the same compound The sorption process of drug-receptor interaction can be interpreted as occupation by drug molecules of sites of the receptor phase Since the taste threshold of a drug can be regarded as drug-receptor interaction registered as sensory perception[8], it appeared of interest to subject taste thresholds for 6-*n*-propylthiouracil and quinine to a biophysical interpretation

The specific impetus to this line of investigation was prompted by our recent finding that mixtures of 6-*n*-propylthiouracil and quinine produced bitter taste in concentrations well below the threshold for either compound alone Another reason for including 6-*n*-propylthiouracil into our studies was that 'non'-tasting of this and other structurally related antithyroid compounds is considered as a genotypical characteristic (see among others ref 8)

Taste thresholds for quinine sulphate and 6-*n*-propylthiouracil were determined in healthy, normal,

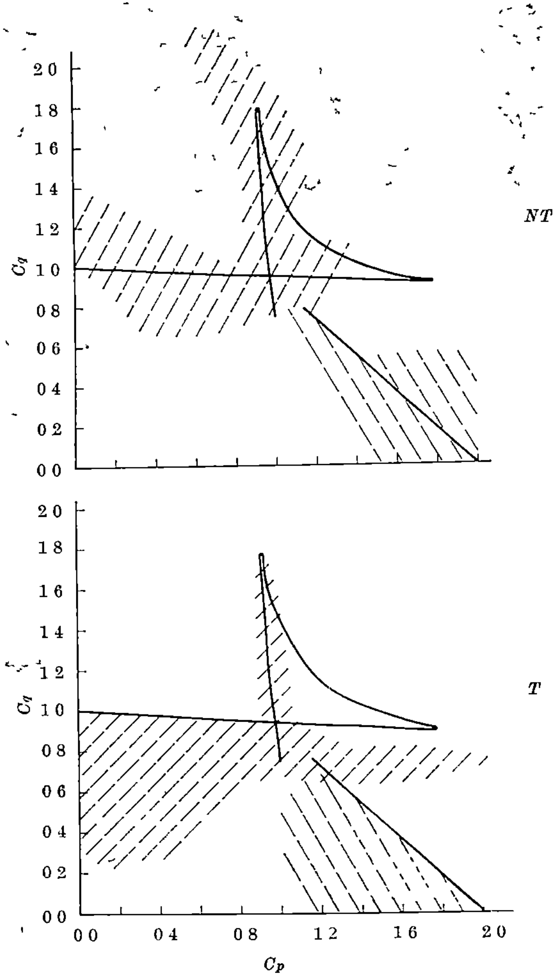

Fig 1 Isothermal taste diagrams for binary mixtures of quinine and 6-*n*-propylthiouracil at room temperature for a typical insensitive ('non'-) taster, called *NT*, and a typical sensitive taster, called *T*, of the compounds $C_q = 1\ 0$ represents the quinine threshold of both *NT* and *T* subjects, whereas $C_p = 1\ 0$ represents 1/2 of the threshold of 6-*n*-propylthiouracil in *NT* subjects and 1/13 of the 6-*n*-propylthiouracil threshold in *T* subjects Representative quinine and 6-*n*-propylthiouracil threshold concentrations for a typical *NT* subject correspond to $1\ 55 \times 10^{-5}$ *M* and $1\ 31 \times 10^{-3}$ *M*, respectively, whereas representative quinine and 6-*n*-propylthiouracil threshold concentrations of a typical *T* subject correspond to $2\ 9 \times 10^{-6}$ *M* and $4\ 37 \times 10^{-5}$ *M*, respectively

Shaded areas indicate concentration combinations of quinine and 6-*n*-propylthiouracil which are not tasted by the subject Note the close correspondence between theoretical curves and experimental data (represented by shaded areas)

trained subjects by the Harris–Kalmus procedure[9,10] This method was used during the training period of a subject which consisted of 1 or 2 threshold determinations per week for at least three weeks The solution numbers represent powers of two, that is, each number denotes a doubling of the concentration, for example, solution number 5 is twice as concentrated as number 4

To increase the resolution of the taste threshold determination, finer concentration intervals based on fractional powers of 2 were prepared, for example, the range between solution Nos 4 and 5 was subdivided into continuous intervals of $2^{1/10}$ With this modification, more refined taste thresholds for series of binary mixtures of quinine and 6-*n*-propylthiouracil were determined The concentration of one compound was held constant while the concentration of the second was decreased in $2^{2/10}$ steps until a taste threshold was reached Then the accuracy of the taste threshold was further increased by the application of the same procedure but using concentration intervals of $2^{1/10}$ steps This procedure was repeated with the order of compounds reversed For each subject approximately 120 combinations of the compounds were tested on two occasions within a five-day period The refined thresholds for quinine and 6-*n*-propylthiouracil (in this order) were determined on each experimental day and used as a base-line The precision of our method is within the limits of a $2^{1/10}$ interval, whereas its accuracy is half as great

In Fig 1 the taste threshold concentrations of a typical insensitive ('non'-) taster for quinine and 6-*n*-propylthiouracil, and a typical sensitive taster for the two bitter compounds are represented as concentrations of quinine plotted against the concentrations of 6-*n*-propylthiouracil The units of concentration in Fig 1 are relative to the values of the particular baseline of the subject on the test day In addition, all concentrations have been adjusted by a constant factor so that the feature of interest appears at values of C_p near one (Fig 1)

The shaded areas represent those concentration combinations of quinine and 6-*n*-propylthiouracil which are not tasted by the subject The unshaded areas (with the exception of the area near the origin) represent concentration combinations of the two drugs which are tasted

Forty combinations were found to be sufficient to define the no-taste areas Between sixty and eighty measurements were necessary to cover the important features of the areas representing tasted combinations The boundary between tasted combinations and non-tasted ones defines a phase diagram for the taste phenomenon Fig 1, in fact, resembles quite closely an isothermal solubility diagram of a pair of salts having an ion in common, both of which are dissolved in a fixed amount of solvent[11]

If drug-receptor interaction is considered as an equilibrium process in taste perception, we can regard the water solution as one of the phases and the taste receptor as the other phase of our system The two components of this system are the two drugs or possibly their positive ions which may combine with sites in the receptor phase and be associated with anions in the solution phase

In order to deal with the taste phenomenon in terms of an isothermal diagram, we have resorted to the regular solution theory of Porter, Heitler and Hildebrand[12–14] We determined the boundary (thresholds) theoretically and compared it with the envelope separating the experimentally determined non-tasted combinations from the tasted ones

In accordance with the notation of Hill[15] we assume that at threshold all available sites of the receptor phase (receptor phase is a hypothetical construct which refers to nodal points in a taste schema attempting to describe the phenomenology of taste[16]) are occupied by N_p molecules of 6-*n*-propylthiouracil and N_q molecules of quinine

For regular solutions then

$$\frac{\mu_q}{kT} = \ln\left(\frac{N_q}{N_q+N_p}\right) - \ln\left[q_q \exp\left(-\frac{CW_{qq}}{2kT}\right)\right] - \frac{CW}{2kT}\left(\frac{N_p}{N_q+N_p}\right)^2$$

and (1)

$$\frac{\mu_p}{kT} = \ln\left(\frac{N_p}{N_p+N_q}\right) - \ln\left[q_p \exp\left(-\frac{CW_{pp}}{2kT}\right)\right] - \frac{CW}{2kT}\left(\frac{N_q}{N_q+N_p}\right)^2$$

where u_q is the chemical potential of quinine in the water phase, q_q is the temperature dependent partition function of quinine in the receptor phase C is the number of nearest neighbours at a site, W_{qq} W_{pp} are the pair interaction energies for quinine and 6-n-propylthiouracil sorbed at adjacent sites W_{pq} is the pair interaction energy at two adjacent sites of one quinine and one 6-n-propylthiouracil molecule, k is Boltzmann's constant and T is the absolute temperature Lastly, $W = W_{qq} + W_{pp} - 2W_{pq}$, p is the chemical potential of 6-n-propylthiouracil in the water phase, q_p is the temperature dependent partition coefficient of 6-n-propylthiouracil

$$\mu_p = kT \ln C_p + \mu_p^0 \qquad (2)$$

$$\mu_q = kT \ln C_q + \mu_q^0$$

where C_p and C_q are the concentrations of 6-n-propylthiouracil and quinine, respectively, in water and μ_p^0, μ_q^0 are the standard chemical potentials of 6-n-propylthiouracil and quinine in the water phase The initial aqueous concentrations given in equations (2) are identical with the concentrations of the taste test solutions since dilution effects by saliva and extraction of the compound by receptor phase are negligible (The volume of a taste test solution is approximately 5 ml , the average volume of saliva secreted during each step of a taste test is approximately 0 04–0 18 ml)

Inserting equations (2) into (1)

$$k_3C_q = \frac{N_q}{N_p + N_q} \exp\left[-\frac{CW}{2kT} \quad \frac{N_p}{N_p + N_q}\Big)^2\right] \qquad (3)$$

$$k_4C_p = \frac{N_p}{N_p + N_q} \exp\left[-\frac{CW}{2kT}\left(\frac{N_q}{N_p + N_q}\right)^2\right]$$

where.

$$k_3 = q_q \exp\left[\frac{\mu_q^0 - \frac{1}{2}CW_{qq}}{kT}\right],\ k_4 = q_q \exp\left[\frac{\mu_p^0 - \frac{1}{2}CW_{pp}}{kT}\right]$$

The values of k_3 and k_4 can be determined from the threshold concentrations of quinine and 6-n-propylthiouracil respectively The value of W was estimated to give a conformation to the theoretical threshold curve which best fits the dividing envelope separating tasted combinations from non-tasted ones

An examination of Fig 1 reveals a qualitative correlation between the leaf-like shape of the theoretical threshold curve and the dividing envelope in the region of high quinine concentrations (for example, those greater than 0 6) The qualitative agreement between the theoretical curves and the experimentally obtained envelopes allows us to make the following conclusions At threshold a certain number of sites in the receptor are occupied by either quinine molecules or an unknown compound formed from quinine and 6-n-propylthiouracil The attraction forces between quinine molecules or the attraction forces between the molecules of the new unknown compound are greater than forces of attraction between molecules of quinine and the new compound This type of interaction in equation 3 gives the leaf-like threshold envelope so long as there are some quinine molecules in the receptor phase

At higher concentrations of 6-n-propylthiouracil (for example, those greater than 1 0) the dividing envelope is a diagonal straight line pointing toward and including the 6-n-propylthiouracil threshold (see lower right portion of both curves in Fig 1) This area, we postulate, corresponds to a receptor phase free of quinine molecules It is not unreasonable, then, to assume that the net attraction forces are zero and the theoretical curve becomes a diagonal straight line corresponding to a perfect solution mixture of 6-n-propylthiouracil and the compound in the receptor phase

The $CW/2kT$ values for a typical insensitive ('non'-) taster and a typical sensitive taster of quinine and 6-n-propylthiouracil are equal to $-$ 3 4 However, the values of the partition coefficients k_3 and k_4 differ for these two taste categories

It should be recalled that there is another important difference between insensitive ('non'-) tasters and sensitive tasters, namely, the significantly greater salivary oxidation rate of the former as compared with the latter[10,17]

The qualitative correlation between the theory of regular solutions applied to the phase rule and experimental evidence allows us to regard taste threshold of a drug or of a mixture of drugs as a specific state of part of the receptor with a given number of receptor sites occupied by drug molecules Taste threshold concentrations of a subject for various compounds are then determined by the number of available sites as well as the magnitudes of the partition coefficients of equations 1

One may speculate about the physical nature of the unoccupied and occupied sites of the receptor phase Volume changes in the latter appear plausible during the sorption process and the concomitant volume change can give rise to mechano-chemical effects, specifically, pressure and swelling[18] of the receptor sites These effects may be part of the chain of events leading to taste sensation

We have introduced this article by regarding taste sensation, with certain restrictions, as drug-receptor interaction Application of the theory of regular solutions to the phase rule allowed us to carry our point farther Fig 1 actually illustrates the dose-response curve for binary mixtures of quinine and 6-n-propylthiouracil Taste or no-taste (shaded) areas correspond to certain combinations of the two drugs and represent phenomena which can be interpreted as synergism and antagonism (as kindly suggested by Dr F W Schueler, New Orleans, La) in the terminology of Gaddum[19]

DIURNAL VARIATION OF THE EARTH'S MAGNETIC FIELD AT SEA

By Dr M N HILL and C S MASON

Department of Geodesy and Geophysics, University of Cambridge

DURING June 20–27, 1961, observations of the total force of the Earth's magnetic field were obtained in four positions with a recording proton precession magnetometer The instrument was contained in a buoy anchored successively at points on the continental slope and at the foot of the continental slope about 120 miles to the south-west of Land's End, in the western approaches of the English Channel The electronics in the buoy consisted of transistorized block units, and the observations were recorded digitally on heat-sensitive paper Dry batteries provided adequate power for up to 15 days recording

A mechanical time-switch cycled the instrument every 5 min and provided hour marks on the record The proton precessional frequency was determined from the time-interval for 2^{10} cycles The accuracy of measurement on land was ± 1γ (10^{-5} œrsted), at sea there may be a larger uncertainty because of motion of the detector coil or because of wave motion

Table 1

Station	Time of operation (B S T)	Position	Water depth (fathoms)
Buoy 1	0900/21/6–1025/22/6	47° 50 5′ N 7° 40 5′ W	450
Buoy 2	1343/22/6–0712/23/6	47° 37 5′ N 7° 44′ W	850
Buoy 3	0956/23/6–0900/25/6	47° 37′ N 7° 43′ W	1,100
Buoy 4	2120/25/6–0855/27/6	47° 22′ N 7° 37 5′ W	2,200
Hartland Point		51° 12′ N 4° 31′ W	
Ivybridge		50° 23′ N 3° 5′ W	

During the period of these measurements at sea, a similar instrument was operated at Ivybridge near Plymouth Total force measurements were available from this instrument at 5-min intervals Advantage has also been taken of the hourly values of the total force obtained by the Royal Greenwich Observatory at Hartland Point, these were computed from the vertical and horizontal hourly values

The positions of the buoy stations and the observatories are given in Table 1

The magnetograms for June 22–23 (buoy 2) and June 26–27 (buoy 4) are shown in Figs 1 and 2 for both the buoy station and Ivybridge, the times shown are G M T + 1 hr Fig 3 shows the average hourly values for all days during June and July 1961, obtained from Hartland Point, and illustrates the relatively steady value of the total force during the night-time hours, typical of land stations in this area

The performance of the buoy magnetometer was checked with a towed proton precession magnetometer The ship steamed on various courses past the buoys and the field values recorded at the point of nearest approach (1–2 cables from the buoys) are shown in Figs 1 and 2

When the conditions are not magnetically disturbed (for example, during the periods of operation of buoys 3 and 4) the daily range is conspicuously greater at sea than at shore (for example, Fig 2) by a factor of about 2 On days magnetically stormy, however, the difference is not so conspicuous (for example, Fig 1)

When the shore observations of the daily variation are subtracted from the buoy observations without

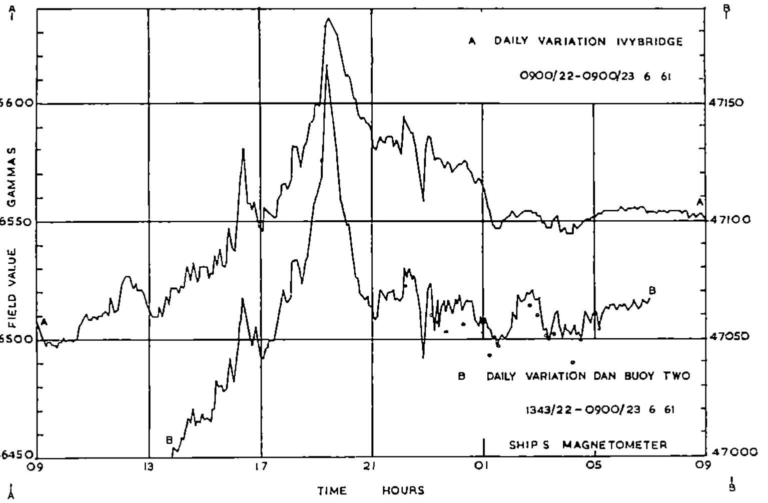

Fig 1

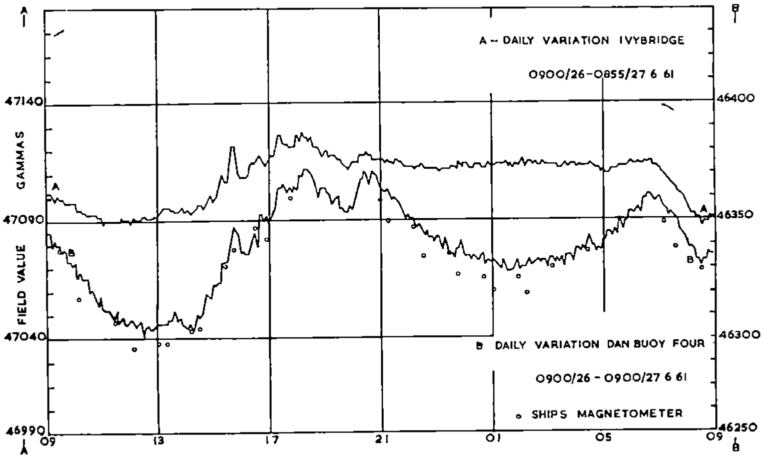

Fig 2

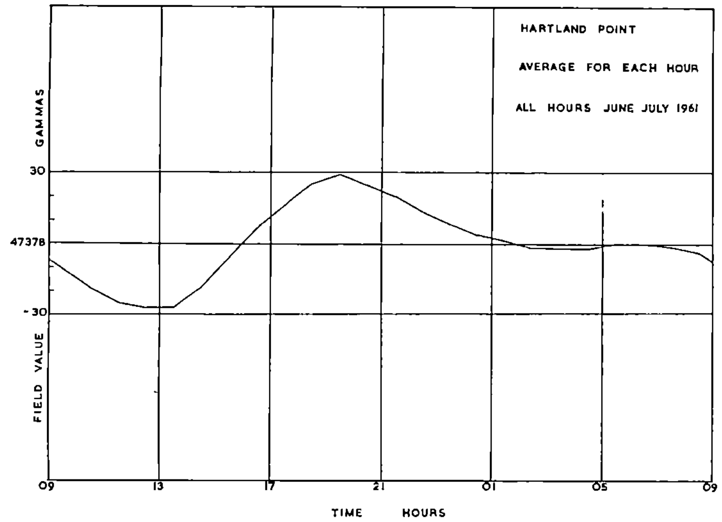

Fig 3

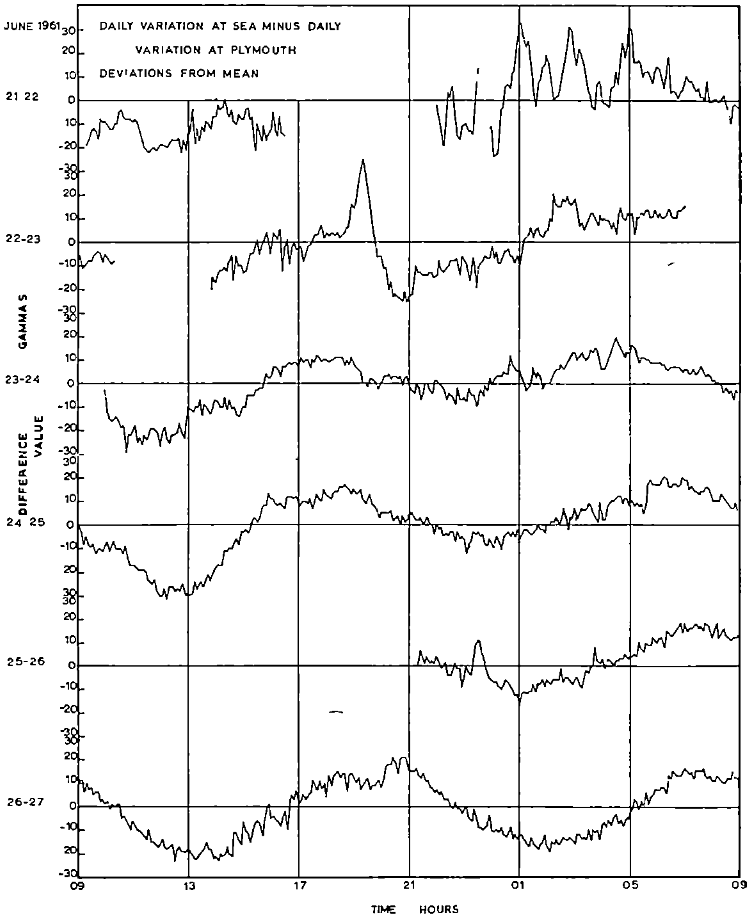

Fig 4

any adjustment for local time difference, the results shown in Fig 4 are obtained These curves (apart from that obtained from buoy 1, where the magnetic storm and the internal failure of the magnetometer between 1630 and 2200 hr obscured the pattern) show a component of change with a period which is probably tidal but which certainly lies between 11 and 14 hr There appears to be a shift to the right of the maxima and minima on the curves of Fig 4 such as would be expected for the semi-diurnal tides Cross-correlation of these curves has not yet been attempted but it might indicate the period with more certainty

The agreement between the ship and buoy magnetometer and the agreement between the magnetic storm details ashore and at sea indicate that the residual effect after the shore variations have been removed is not instrumental It was, however, possible that the variation could be explained by tidal drift of the buoys due to the scope of their mooring wires Precise positioning of the buoys by radio or celestial methods was not possible, but from the known topography and magnetic field around the buoys it has been possible to eliminate buoy drift as an explanation of this semi-diurnal component It is possible that this component, shown in the curves of Fig 4, will only exist near the continental boundary, measurements farther out into the ocean basins are not yet available

These results shown in Fig 4 are unexpected but are probably caused by induced electrical currents in the sea resulting from the tidal motion of the water in the Earth's magnetic field A lunar component of magnetic variation is observed ashore but this is much smaller than that observed in these experiments Theoretical and model studies are now being undertaken in this Department

Because of the electrical conductivity of sea-water some screening effect of magnetic variations might be expected This is not observed either with the normal solar daily variation or with the shorter period (½–2 hr) variations produced by magnetic storms (for example, Fig 1) The effect may exist at periods shorter than about 10 min , this could not have been observed because of the low sampling-rate in the field measurements

We thank Dr H F Finch, Royal Greenwich Observatory, who provided the results from Hartland Observatory, S J E Humphrey, who operated the nuclear precession magnetometer at Ivybridge, the Director of the Marine Biological Association for allowing us to sail in R V *Sarsia*, and the officers and crew for their assistance This work was undertaken under the United States Office of Naval Research Contract *N* 62558–2704, the Shell International Petroleum Co provided a scholarship

LETTERS TO THE EDITOR

ASTROPHYSICS

A New Upper Limit to the Galactic Deuterium-to-Hydrogen Ratio

THE detection of the 21-cm hydrogen line, in 1951, created interest in the possibility of detecting a similar deuterium line at a wave-length of 91 6 cm By comparing the strengths of the two lines, the galactic deuterium-to-hydrogen ratio, N_D/N_H, could be determined This quantity is of astrophysical interest because it will give information about the composition and nucleogenesis of the interstellar medium[1,2]

There have been four previous attempts to detect the deuterium line, and all have given negative results[3-6] The most recent of these, at Jodrell Bank, set an upper limit on N_D/N_H of 1/4,000 in the direction of the Cassiopeia radio source, this value is slightly higher than the terrestrial abundance ratio of 1/6,700

Our work has consisted of attempting to observe deuterium absorption in the Cassiopeia *A* radio source The 85-ft telescope of the National Radio Astronomy Observatory, at Green Bank, West Virginia, was used to track Cassiopeia *A* 12 hr a day for 9 weeks The receiving system has been described elsewhere[7] It incorporates two techniques (1) The autocorrelation function of the signal is determined digitally and Fourier-transformed by a computer to give the power spectrum Use of this method gives high stability and permits multichannel operation (the spectrum is measured at many frequencies during the same time interval) (2) The effective observation time is quadrupled by using four switched receivers to monitor both polarizations all of the time It was thus possible to have 76 5 days (6 6 × 10^6 sec) of effective observation time, even though the antenna was in use only 68 days

The sensitivity of the autocorrelation system has been investigated theoretically[8], and also been checked by computer simulation The root mean square deviation, ΔT, of the spectral measurement is given by

$$\Delta T = \frac{2\ 1}{\sqrt{Bt}}\, T_{\text{tot}}$$

where $B = 3\ 75$ kc /s is the frequency resolution of the measurement $t = 6\ 6 \times 10^6$ sec is the observation time, and $T_{\text{tot}} = 2{,}000°$ is the total noise temperature referred to the receiver input These values give $\Delta T = 0\ 027°$

The spectral dip, T_D, resulting from deuterium absorption, is given by

$$T_D = \tau_D T_p$$

where $T_p = 0\ 46\ \ T_{\text{tot}}$ is the contribution to the receiver input arising from the background source, Cassiopeia *A*, and τ_D is the deuterium optical depth in the angle subtended by the source

The relation relating τ_D to N_D/N_H which we have calculated differs from those given previously by Shklovsky[9] and Adgie[10] The peak optical depth of either gas[11] is given by

$$\tau = \frac{hc^2}{8\pi k}\ \frac{A}{T_s f_0 \Delta f}\ \frac{g_1}{g_1 + g_0}\ N$$

where *A* is the spontaneous emission probability, T_s is the spin temperature, f_0 is the line frequency, Δf is the Doppler-broadened line-width, g_1 and g_0 are the statistical weights of the upper and lower states, and *N* is the total number of atoms per unit cross-section in the two states Calculating the ratio of these quantities for deuterium and hydrogen gives

$$\frac{\tau_D}{\tau_H} = 0\ 33\,\frac{N_D}{N_H}$$

The following assumptions have been made

(1) The value $A_d = 4\ 65 \times 10^{-17}$ sec $^{-1}$ given by Field[12] is correct (this result has been computed independently by A H Barrett of this Laboratory), and the value 6 6 × 10^{-17} sec $^{-1}$ given by Shklovsky is incorrect

(2) The ratio of the Doppler-broadened line-widths $\Delta f_D/\Delta f_H$ would be equal to f_D/f_H if the atoms had the same root mean square velocities However, approximately half the broadening is due to thermal motion in which the deuterium atoms, having twice the mass, would have $1/\sqrt{2}$ of the root mean square hydrogen velocity

$$\text{Thus } \Delta f_D/\Delta f_H = [1/2 + 1/(2\sqrt{2})]\, f_D/f_H$$

(3) The spin temperatures for hydrogen and deuterium are assumed to be equal Justification of this assumption is uncertain, since it depends on estimates of the intensity and detailed profile of the interstellar radiation field at the frequency of deuterium Lyman α-radiation[12]

The value of the peak hydrogen optical depth in the Cassiopeia *A* radio source is also the subject of some controversy, its large value being difficult to measure The first observers, Hagen, Lilley and McClain[13], using a 50-ft paraboloid, report $\tau_H = 2\ 6$ Muller[14], using an 83-ft reflector, gives 4 0, and observers at California Institute of Technology[15], using a single 90-ft telescope, report $\tau_H > 4\ 7$, and $3\ 4 \pm 0\ 4$ when using two 90-ft telescopes as an interferometer Accepting a value of peak hydrogen optical depth of 4, multiplying this by 0 8 to account for reduction because of the 3 75-kc /s band-width, and assuming a detection criterion of twice the theoretical root mean square fluctuation, we obtain a minimum detectable N_D/N_H of 1/18,000

Our results are illustrated in Fig 1 Individual 10-hr runs were examined for interference, corrected for any slope (typical slope correction, 0 03°/kc /s), and averaged into 3-week lots Examination of the 3-week averages indicates that the root mean square deviation is approximately 1 4 times the theoretical value, and thus the minimum detectable N_D/N_H should be raised to ~1/13,000 Our conclusion, then, is that the deuterium-to-hydrogen ratio in the region examined is, with probability 0 977, less than half the terrestrial value

I thank the staff of the National Radio Astronomy Observatory for providing observing facilities and

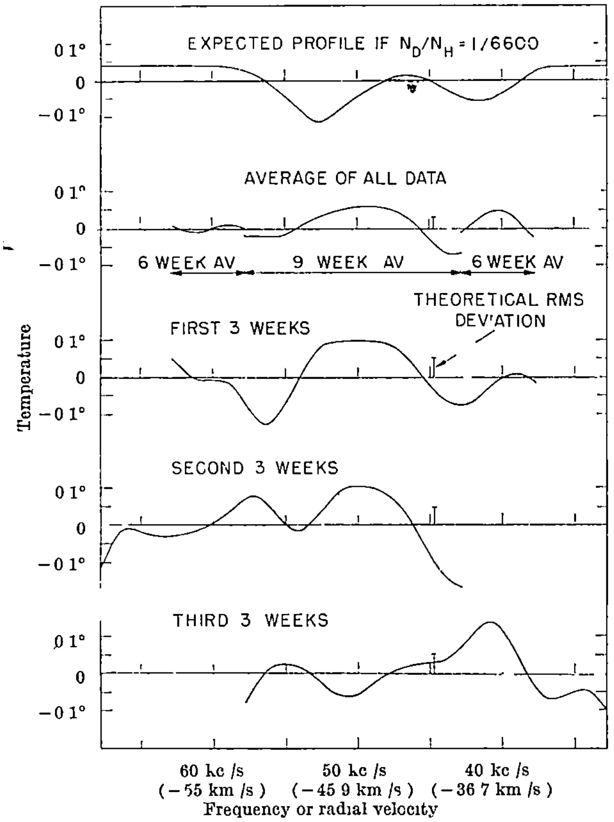

Fig 1 Results of search for 327-mc /s deuterium line absorption in the Cassiopeia *A* radio source

supporting personnel, Prof J B Wiesner for his encouragement and supervision, and Dr H I Ewen for, in many ways, providing the spark that initiated the research I wish to acknowledge the use of the computer facility of the Computation Center, of this Institute in part of this work This investigation was supported in part by the U S Army Signal Corps, the Air Force Office of Scientific Research, and the Office of Naval Research, and in part by the National Science Foundation (grant *G*–13904)

GEOPHYSICS

Terrestrial Flow of Heat Near Flin Flon, Manitoba

Preliminary measurements of underground temperatures and thermal conductivity have been made in the Coronation Mine near Flin Flon, Manitoba The work is part of a comprehensive geological–geophysical–geochemical investigation of the mine, made possible by the enlightened policies of the Hudson Bay Mining and Smelting Co , who has allowed free use of the mine, even when it interrupted production schedules

Coronation is a copper sulphide orebody in basic volcanics and consists of two lenses, about 300 ft long, which dip steeply southwards The two lenses are separated by about 200 ft of low-grade disseminated ore and extend 900–1,050 ft below the surface The mine is therefore a small one being about 300 ft wide, 900 ft long, and 1,050 ft deep The drift depths are in increments of 150 ft from the surface down to 1,050 ft with an exploratory drift at 1,350 ft

There are numerous drill holes throughout the mine, but only those that were horizontal and open to at least 40 ft from the drift wall were used As the mine was less than 5 years old the distance of 40 ft is well beyond the region of disturbance of temperature due to ventilation[1,2], in some cases penetrations up to 180 ft from the wall were made Water was issuing from some of the holes, but in most of such cases it was possible to push the thermistor temperature sensing element beyond the point of entry of the water so that true rock temperatures could be obtained

Not less than ten readings of temperature were obtained at each drift depth, and the average of these was taken as the temperature of a particular level Between 550 and 600 ft a small but significant change in gradient, which could not be correlated with a change in rock conductivity, was observed, the two gradients together with their respective 95 per cent confidence limits, were 15 3 ± 0 8° C /km to 600 ft and 11 7 ± 1 2° C /km from 600 to 1,350 ft

The thermal conductivities (expressed in c g s units) of rock samples varied from 0 0047 for an andesite to 0 0092 for a tremolite gneiss, showing extensive mineralization The mean for the mineralized rocks is 0 008 and for unmineralized rocks is 0 006, the errors being such that use of the second figure is not warranted Thus from 150 to 600 ft the flow of heat lies between 0 9 and 1 2 µcal /sq cm /sec and from 600 to 1,350 ft it lies between 0 7 and 0 9 µcal /sq cm /sec

Since the temperatures were measured in or near an ore body it is to be expected that the temperature gradient will be low and should be accompanied by a high thermal conductivity For this reason the temperature gradients should be used with the higher value of conductivity given for the mineralized rocks, although without an extensive number of measurements it would be difficult to obtain an accurate mean value

There are a number of factors which could have affected the value of flow of heat[3], in this mine the most important is the probable occurrence of flows of water in the region particularly in the upper parts of the mine The evidence for this, in addition to the flow of water from some of the drill holes, was provided by the tritium dates of two water samples which indicated that the water from the 1,050-ft level was about 25 years older than that from the surface Since this is a point of some importance in determination of flow of terrestrial heat, further water samples will be collected from different levels and their tritium dates found in an effort to determine the pattern and extent of underground water flow before more extensive heat-flow measurements are made.

I thank the National Research Council of Canada for a grant-in-aid, Dr. D. R. E. Whitmore for much information and assistance in the field, and the members of staff of the Hudson Bay Mining and Smelting Co. for their co-operation.

PHYSICS

X-ray Microanalysis of a Radioactive Particle with the Aid of the Electron Microscope*

In the examination of radioactive fall-out the phenomenon of the radioactive particles has recently attracted growing attention[1,2]. It has become evident that a considerable part of the artificial radioactivity in the atmosphere, caused by atomic explosions, is found in the form of finest 'dust' particles. These may be inhaled or ingested and possibly cause radiation damage.

To make statements on such biological effects an exact knowledge of the physical and chemical characteristics (such as size, structure, composition, solubility) is needed. By means of γ-spectrometric and radiochemical methods the radioactive nuclides in the particles can be detected; the determination of size and shape of a particle is made possible by electron microscopy[3]. Estimates based on activity and diameter of the radioactive particles have shown that they must even at the time of their formation consist partly of inactive material[1,3]. Information concerning the inactive components is important for the question of formation of particles as well as for the problem of their solubility.

Radioactive particles which were collected and examined during a period of three months following the atomic test series of September 1961 were the subject of a recent publication[3]. One of these particles (Fig. 1) was analysed in an electron microscope (Elmiskop I, Siemens) by an X-ray microanalytical method[4]. (The spectra were recorded with the help of Dr. H. Neff and Miss E. Schmiedeskamp with the apparatus of the Siemens Werk für Messtechnik in Karlsruhe.) The aim of this investigation was to obtain information about the composition of the inactive material of the particle. The microanalytical method mentioned uses the X-ray line spectrum of the K-series (characterized mainly by the $K\alpha_1$-quantum energy) which is caused by electron irradiation of the particle in the electron microscope and which is characteristic of each element. The electron beam is focused on the object and the emerging X-ray spectrum is absorbed in a proportional counter. The counter pulses are conducted to an impulse spectroscope from which the spectrum is then photographically recorded with a 'Polaroid' camera. For the time being the method admits the identification of elements of the ordinal numbers 13–40.

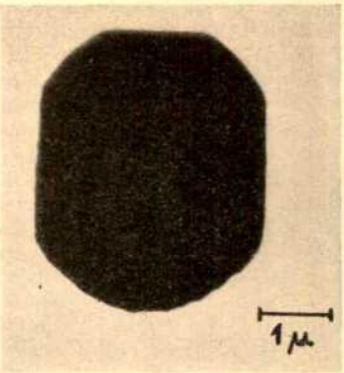

Fig. 1. Outline of a radioactive particle collected in October 1961; activity at the collecting-date 5×10^{-10} c.; largest diameter, 4·4μ. Electron micrograph

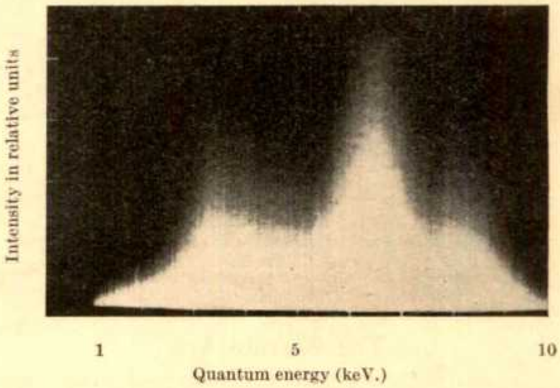

Fig. 2. X-ray microanalysis of the radioactive particle shown in Fig. 1. Beam voltage, 40 kV. A beryllium window diminishes the amount of scattered radiation, but at the same time also the effect of the low-energetic quanta (0–2 keV. range). One easily recognizes the iron peak at 6·4 keV. and the iron escape peak at about 3·5 keV. The peak at about 8·0 keV. (copper) is caused by the bronze grid used and does not belong to the spectrum of the radioactive particle

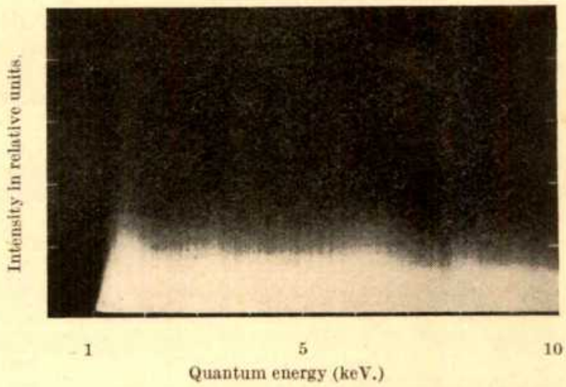

Fig. 3. X-ray microanalysis of the radioactive particle shown in Fig. 1. Beam voltage, 40 kV. Without beryllium window. The amount of scattered radiation is remarkably high but the spectrum covers also the low-energetic range. Due to the high amount of scattered radiation, the time of exposition had to be shorter than in Fig. 2. Therefore the peaks are less distinct. Nevertheless, one now recognizes besides the iron peak and the iron escape peak an additional peak at about 1·6 keV., which is caused either by aluminium (1·48 keV.) or by silicon (1·74 keV.). As in Fig. 2, there is a peak at about 8·0 keV. caused by the copper of the bronze grid used

In the particle analysed we found iron and aluminium or silicon as inactive components. This result was inferred from the spectra shown in Figs. 2 and 3. In the method used there are difficulties in separating elements if their $K\alpha_1$-energies differ only very little. Therefore the existence of iron ($K\alpha_1$-quantum energy 6·40 keV.) can be deduced with certainty from the spectra obtained; there is no clear answer to the question, however, whether the second component is aluminium or silicon. The $K\alpha_1$-energies of these two elements (aluminium, 1·48 keV.; silicon, 1·74 keV.) differ only by 0·26 keV.

A peak at about 8 keV. which is discernible in the spectra given was also found after having focused the electron beam on to the empty methacrylate foil beside the radioactive particle. Without doubt this peak belongs to the copper ($K\alpha_1$-quantum energy, 8·0 keV.) of the bronze grid on which the particle had been introduced into the electron microscope.

In view of these results it appears reasonable to continue with improved methods the examination of radioactive particles with regard to their inactive parts.

The Bertele Arc

UNDER this title, Prof. D. Gabor[1] has made some very interesting observations about an unusual type of low-pressure mercury vapour discharge, which was first observed by Dr. H. von Bertele[2]. The cathode, a water-cooled molybdenum thimble of 1 cm.^{2} area, dips in a trough of mercury, and the 15-amp. arc appears gradually to spread over its entire surface as a "faintly luminous glow".

A significant fact, observed by Prof. Gabor, is that high-speed photographs, with exposure time of 1/15,000 sec., show the glow covering only about 1/10 of the surface, having a "complicated ramified appearance", and increasing in area proportionally to the current. This fact, plus some observations on the "noise" spectrum, forces Prof. Gabor to conclude that the discharge is some kind of a glow discharge, in spite of its impossibly low voltage drop of 10 V., and impossibly high current density of 150 amp./cm.^{2}.

The 10-V. cathode drop supports strongly the suggestion of Dr. A. Robson that this is a normal mercury arc, with a "cathode spot" of current density 10^5 amp./cm.^{2} (ref. 3) running over the surface at high speed. A simple calculation shows that this description fits the observed data remarkably well.

I assume, with Gabor, that the molybdenum is covered with a monatomic film of mercury, and interpret the "forming" period as the time necessary to clean the surface of its oxide layer. It is well known that mercury will not 'wet' molybdenum unless scrupulously clean; in fact, a surface once wetted, for example by cleaving under mercury, becomes quickly 'unwetted' on standing in a fairly good vacuum.

Let us first calculate the velocity of the "cathode spot". This is determined by the time, τ, necessary to evaporate the monatomic film, since the spot must move when it has exhausted its supply of mercury.

The number of atoms in the monatomic film, as given by the closest assembly of possible sites on a 111 molybdenum surface, is $N = 3{\cdot}9 \times 10^{14}$ atoms/cm.^{2}. The rate of evaporation at $T°$ K. and $p_{\text{mm.}}$ mercury pressure is $n = 3{\cdot}51 \times 10^{22}\, p/\sqrt{MT}$ (M = mol. wt.). Hence

$$\tau = \frac{N}{n} = \frac{3{\cdot}9 \times 10^{14}}{3{\cdot}51 \times 10^{22} p/\sqrt{MT}} = 1{\cdot}57 \times 10^{-7}\,\frac{\sqrt{T}}{p_{\text{mm.}}} \quad (1)$$

A second relation between τ and T is given by the time necessary to raise the temperature from 300° K. (temperature of cooling water) to T, namely:

$$\tau = \frac{\pi}{k}\,\frac{(\Delta T)^2K^2}{4Q^2}\ \text{(ref. 4)} \qquad (2)$$

$\Delta T = T - 300$, K = thermal conductivity of molybdenum = 1·38 W./cm. °K., k = diffusivity of molybdenum = 0·73 cm.^{2}/sec., $Q = (V_c + V_i - \varphi_0) \times \frac{I_0}{10}$, where V_c = cathode drop = 10 V., V_i = ionizing potential = 10·4 V., φ_0 = work function = 4·5 V., and $\frac{I_0}{10}$ = positive ion current density[5], I_0 = electron current density = 10^5 amp./cm.^{2}.

Eliminating T (and $p(T)$) between equations (1) and (2) yields:

$$\tau = 1{\cdot}18 \times 10^{-6}\ \text{sec.}\ (T = 422°\ \text{K.}, p = 2{\cdot}75\ \text{mm.})$$

The velocity with which a spot of current i moves over the surface is:

$$\text{vel.} = \frac{\text{diam. of spot}}{\tau} = \frac{2\sqrt{i/\pi \times 10^5}}{1{\cdot}18 \times 10^{-6}} = 3{\cdot}00 \times 10^3\sqrt{i} \quad (3)$$

$= 1{\cdot}17 \times 10^4$ cm./sec. for i = 15 amp.

This velocity is slow enough to be resolved in a 1/15,000 sec. exposure. In fact, it is so resolved, though not as a straight line but as the area of the 'random walk' of the cathode spot.

The motion of the spot is not completely 'random'. When it exhausts the mercury film in one place and has to move, it cannot move backward, since that is where it last came from and the mercury film there is exhausted. But it has an equal probability of moving forward, to the right, or to the left.

The distance moved forward in 1/15,000 sec. will be 1/3 vel. × 1/15,000 = 0·250 cm. This is the total forward distance, a very tortuous line. The distance laterally, at right angles to the forward path, will be a 'random walk' with a mean value ± 0·558 mm. = 1·16 mm. mean width[6].

Hence the area swept over by the spot in 1/15,000 sec., which is the area that is luminous during the time of the photograph, is:

$$\text{area} = 0{\cdot}26 \times 0{\cdot}116 = 0{\cdot}03\ \text{cm.}^2$$

However, since the motion of the spot is tortuous, its ramifications will include a much larger area, and the extent of the "ramified" area should approximate the 0·1 cm.^{2} observed. Also, this area will increase, approximately, in proportion to the current (the square of linear velocity, equation 3), as observed.

Gabor also measured the noise spectrum, and reports: "In the range up to 50 kilocycles the noise power is flat; beyond this there is a rapid fall-off with a complete cut-off at about a megacycle". This is just the spectrum to be expected from plasma ion oscillations, for which Tonks and Langmuir[7] report a maximum frequency "less than 1·5 megacycles", with a rapid fall-off from a frequency 1/25 of this value, namely, 60 kc./s. Cobine and Gallagher[8], who made a systematic study of total noise from arc discharges, found the spectrum for a mercury discharge flat out to a 'transition frequency' of 260 kc./s., with rapid fall-off above that to complete cut-off at 8 mc.

Hence it appears that the spectrum observed by Prof. Gabor is a reasonable one for a normal mercury arc.

Note: If the surface of molybdenum is covered with a thick film of mercury, rather than a monatomic layer, the velocity of the spot will be $6\cdot 1 \times 10^3 \sqrt{i}$[9] rather than $3\cdot 0 \times 10^3 \sqrt{i}$, and the area swept over will be four times as great, which is still closer to the observed value.

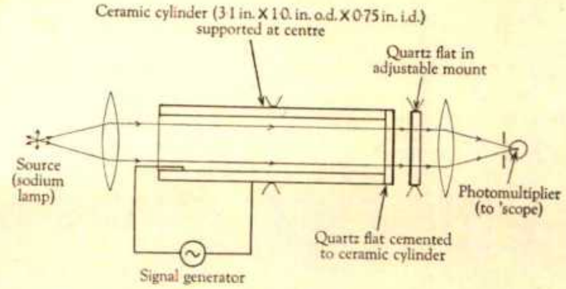
An Ultra-Rapid Scanning Fabry–Perot Interferometer

IT is well known that the profile of a spectral line may be time-resolved by an arrangement in which light is passed normally through a Fabry–Perot etalon, the spacing of which is varied in time, while a photomultiplier looks at the central fringe of the circular (Haidinger) pattern.

Here we have used a piezo-electric barium titanate element to control the etalon spacing. The method gave a scan speed of one fringe in 3 μsec. to be compared with 100 μsec. obtained by Bradley[1], who suspended the moving mirror in a mechanical vibrating system driven by a solenoid, and with 50 μsec. obtained by Koloshnikov *et al.*[2], who used the linear displacement of a ceramic element.

The apparatus is shown schematically in Fig. 1. Light was passed axially through the hollow cylinder of barium titanate, the two cylindrical surfaces of which had been silvered to form electrodes. To the end of this cylinder was attached a fused quartz optical flat (polished flat to λ/10 and silvered to a reflectivity of 80–85 per cent) which formed one plate of the interferometer. The ceramic tube was clamped at its centre and driven at parallel resonance in its lengthwise mode (a frequency of 27·8 kc./s.) by means of an audio-frequency signal generator. The other plate was an identical quartz flat, mounted in an adjustable stand to allow initial alignment to parallelism.

To test the apparatus experimentally the sodium *D* lines emitted by a standard sodium lamp were scanned; Fig. 2 shows a typical oscilloscope recording. The lower half of the figure shows the voltage applied across the ceramic tube, in this case approximately 30 V. peak-to-peak, while the upper half shows the output of the photomultiplier (*IP*21). In the two regions *AA′*, *BB′*, the rate of change of voltage with time is approximately constant, since the displacement of the ceramic is directly proportional to the applied voltage, and since the wave-length observed by the photomultiplier is directly dependent on the separation of the interferometer plates, in these two regions the linear time-base is also the linear wave-length scale. As three orders of the fringe pattern were scanned per half-period, the second order lies clearly in the region of linear wave-length scale, and so using the doublet separation as a standard wave-length interval of 6 Å. the half-widths of the two *D* lines were easily measured. Both lines had a half-width of about 3 Å. and the free spectral range of the etalon was 14·5 ± 0·5 Å., this interval being scanned in 3·5 μsec.



Ceramic cylinder (3·1 in. × 1·0. in. o.d. × 0·75 in. i.d.) supported at centre
Quartz flat in adjustable mount
Source (sodium lamp)
Photomultiplier (to 'scope)
Quartz flat cemented to ceramic cylinder
Signal generator

Fig. 1. Schematic diagram of scanning Fabry–Perot interferometer

With an initial plate flatness of λ/10 the instrumental width due to flatness alone would be approximately 3 Å., and if the effective flatness were increased to λ/15, when only half aperture was used, the instrumental width due to flatness would still be about 2 Å. Therefore, allowing a further instrumental width of 1 Å. for the effects of reflectivity and the rise-time of the amplifier (0·1 μsec.), the instrumental width caused by distortion of the moving plate and lack of parallelism of the movement must be 2 Å. or less, that is, the quality of the movement is as good as the flatness of the Fabry–Perot plates. A second interferometer has already been designed with plates flat to λ/50 so that more stringent tests can be made on this method of scanning.

It is important to realize that although only three orders of the fringe pattern have been scanned in the case of Fig. 2, the power input to the ceramic resonator was less than 0·01 W. With a power input of 1 W., twenty orders were scanned per half-period (that is, in 15 μsec.) so that one order was scanned

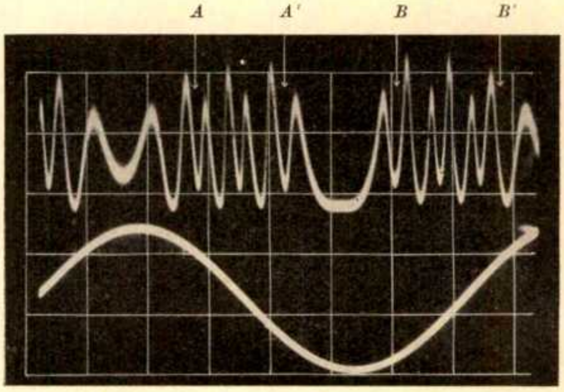


Fig. 2. Oscilloscope recording. Time base 5 μsec. per division

in 0·5 μsec. and a single spectral line could be scanned with this arrangement in about 0·1 μsec. The resolution at such a rapid scanning-rate is limited with the present arrangement by the amplifier rise-time and shot-noise from the photomultiplier.

The maximum possible time resolution is governed by the half-period of the ceramic resonator and the number of fringes scanned in that time. Thus it might be thought that the time resolution could be increased if an interferometer were designed to work at a higher resonant frequency. There is, however, a limit to this process: to prevent the moving Fabry–Perot plate resonating in its flexural mode (such a vibration would of course destroy the Haidinger fringe pattern) the resonant flexural frequency of the moving plate should be at least twice the resonant scanning frequency. With the present system the flexural frequency of the moving plate is only 50 kc./s., which is rather low and probably accounts for the marked increase in resolution when the aperture is decreased by inserting an aperture stop. In the new interferometer the flexural frequency of the moving plate will be 100 kc./s., the scanning frequency remaining at about 30 kc./s.

This instrument, with its time resolution of better than 0·5 μsec. coupled with the large light-gathering capacity, the direct display of the line intensity profile, and other advantages of the scanned Fabry–Perot interferometer, will be especially useful for investigating the physical conditions within pulsed discharges used in controlled fusion research.

Observations on Gaseous Detonation Waves using a Microwave Interferometer

Considerable attention has been devoted to the study of the structure of the reaction zone in gaseous detonation waves with the view of providing information on the duration and quantitative variations occurring in the gas parameters. In order to make these variations amenable to experimental study the waves are usually generated in mixtures at reduced initial pressures so as to prolong the duration of the reaction. If the overall reaction is second order the reaction time is then inversely proportional to the initial pressure.

Unfortunately, at low initial pressures, great difficulty is encountered in some mixtures in establishing an unsupported stable wave. The main criterion of stability is often taken to be the constancy of the wave velocity, which is normally measured over several lengths of the detonation tube preceding the observation section. The desirability of providing a continuous monitor of the velocity over the long lengths of tube, which are necessary at low pressure, is evident. For this purpose the feasibility of using a 3-cm. microwave interferometer[1] has been investigated; this utilizes the interference effect between a microwave beam, launched at the closed end of the detonation tube, and the beam reflected from the dielectric discontinuity at the detonation front.

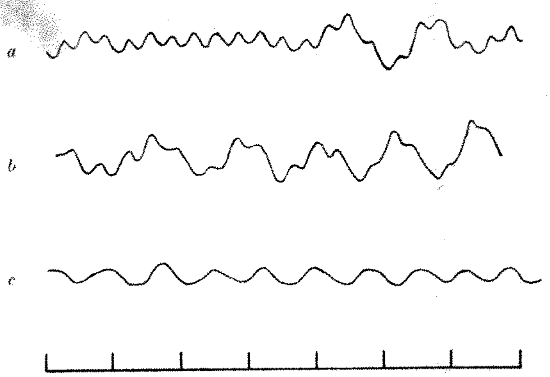

Fig. 1. Single lines of oscilloscope raster sweep display of microwave interferograms obtained from detonation waves in $2H_2 + O_2$ at initial pressures of (*a*) 300, (*b*) 200 and (*c*) 100 mm.

In our preliminary work, the mixture which has been mainly investigated is $2H_2 + O_2$, for which the duration of the reaction zone is ~ 2 μs. in observer's time, at an initial pressure of 100 mm. of mercury. The detonation tube is made of stainless steel, 15 m. long and 5 cm. diameter. Detonation is initiated by a $C_2H_2 + O_2$ mixture, contained in a 1-m. long driving section, which is ignited by an 8-joule spark. The calculated electron density in $2H_2 + O_2$, with the addition of $\frac{3}{8}$ per cent nitrogen as a controlled impurity-level, at 300 mm. of mercury, is $0{\cdot}75 \times 10^{12}$ electrons/c.c. (ref. 2); the 'skin depth', assuming a step profile for ionization for a wavelength of 3 cm., is 10 cm. and the power attenuation of the signal on reflexion is 16 db.

The salient features of the observations made hitherto are the following. At initial pressures down to approximately 500 mm. the reflected power is too small to be detectable with the apparatus available. From about 450–350 mm. pressure, a sinusoidal interferogram is obtained over the whole length of the tube which corresponds closely to the predicted detonation velocity of 2,800 m./s. When a pressure of 300 mm. is reached the regularity of the pattern is intermittently broken by a lower frequency modulation, as shown in Fig. 1*a*; this would correspond to a region moving with a velocity of 850 m./s. This value is well below the mass velocity of the gas at the *C–J* plane of 1,200 m./s.; consequently, its origin is open to conjecture. One may hazard the opinion that it arises from some periodic instability of the front, such as 'spin', which appears to occur frequently at low pressure[3]. The observed reflected power loss at this pressure is 20 db., which agrees reasonably well with the above estimated value. Similar records are obtained at 200 mm. pressure, Fig. 1*b*, except that the lower frequency is always present superposed on a higher frequency corresponding to the detonation front velocity. At 100 mm. the electron density in the reaction zone is insufficient to reflect the microwaves, but reflexions are obtained from a region of ionization travelling with the mass velocity of the gas of 1,200 m./s. Waves in $C_2H_2 + O_2$ exhibit perfectly normal interferograms down to initial pressures of 20 mm.

The non-uniformity of the ionization across the detonation front in $2H_2 + O_2$ provides further evidence[3] of the non-ideality of these waves at fairly high initial pressures. Moreover, the results emphasize the inadequacy of velocity measurements alone as a criterion of wave stability.

METALLURGY

Substructures in Nickel grown from the Melt

As part of an investigation into the effect of substrate structure on the nucleation and growth of electro-deposits, it was desired to produce in a metal single crystal of high purity various types of imperfection. 'Striation'[1] boundaries and cell boundaries ('corrugation'[2] boundaries) were thought to be suitable as the former should give low-angle boundaries ($\frac{1}{4}$°–5°) with little impurity while the latter should illustrate the effect on nucleation of the impurity contained in cell boundaries.

Floating-zone melting was used to make the single crystals, as contamination is minimized in this way[3]. Preliminary experiments showed that nickel rod of 4 mm. diameter was quite tractable in the electron bombardment apparatus used[4].

A Berg–Barrett X-ray micrographic technique[5] was used for examining the substructures obtained. Specimens of about 2 × 3 × 4 mm. were cut from the rod crystals and these were ground and electropolished to remove the work-hardened layers produced by cutting. A chromium target was used[5], and the radiation was neither filtered nor monochromated. In order to bathe the whole specimen with X-rays, a 10-mm. diameter beam was used and it was found to be necessary to evacuate the long lead collimator tube to reduce absorption of the soft radiation. Kodak *B*10 photographic plates were used to record the images as although these plates have a poorer resolution than Kodak Maximum Resolution plates, they require only short exposures and have proved to be very easy to handle and process.

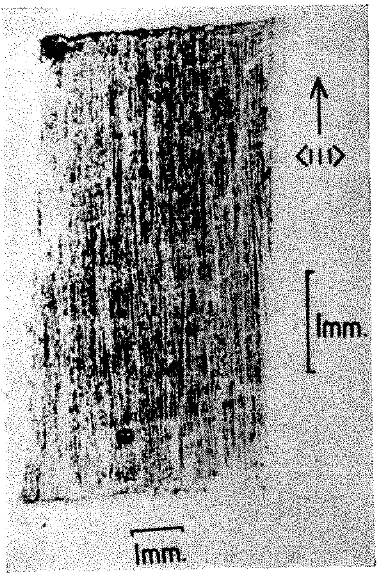

Fig. 1. A Berg–Barrett micrograph of a <111> specimen showing corrugations

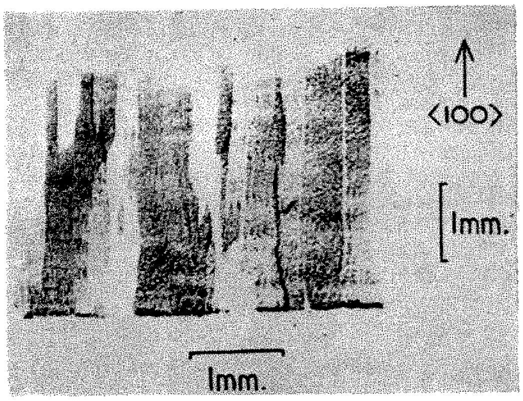

Fig. 2. A Berg–Barrett micrograph of a <100> specimen showing striations and cells

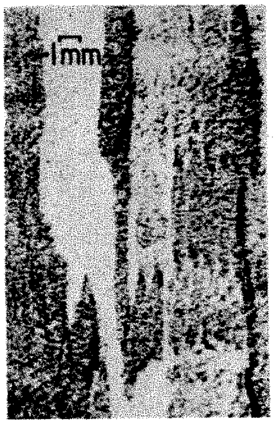

Fig. 3. An enlargement of Fig. 2 showing cells

It is thought that resolution of detail in the image may have been impaired by the distortions induced by sawing and grinding despite the electropolishing treatment, and a chemical saw has been built to eliminate this distortion in future.

In seven experiments, random nucleation of single crystals from polycrystalline rods produced crystal orientations within 10° of <111>. (Orientations refer to the crystallographic direction lying along the rod axis. This is the heat flow axis and hence the direction of growth of the solid front.) This is in accordance with the data of Rosenberg and Tiller[6] which give the preferred growth orientation for pure face-centred cubic metals as <111>. In a <111> crystal grown at 4 mm./min., corrugations were produced, but no striations were seen on the Berg–Barrett image (Fig. 1). The absence of striations in this specimen may be due to the fact that, at fast rates of growth, striations form parallel to a direction <*hkl*>[1], and if this direction is inclined at a large angle to the growth axis, <111> in this case, then 'latent' striations may have grown out of the rod during the incubation period[7]. Aust and Chalmers[8] state that the <*hkl*> for the face-centred cubic aluminium is <100>, which is inclined at 54° 44′ to <111>, and it may also be <100> in the case of nickel.

With the use of a < 100 > seed crystal cut from one of the < 111 > rods, crystals with orientations near to < 100 > were obtained and in these both striations and corrugations were apparent at a growth-rate of 13 mm./min. The Berg–Barrett micrograph (Fig. 2) shows the striations running approximately parallel to the growth direction < 100 > and an enlargement of a region of a striation (Fig. 3) shows a cell structure resulting from impurity segregation.

Although mention is made of the occurrence of striations[9] and corrugations[2] in nickel, no published data have been found on the sub-structure dimensions. The present results are, however, compared in Table 1 with the published data on tin by Chalmers *et al.*

Table 1. SUBSTRUCTURE DIMENSIONS IN NICKEL AND TIN

	Striations			Cells (corrugations)		
	Orientation	Growth-rate (mm./min.)	Width (mm.)	Orientation	Growth-rate (mm./min.)	Width (mm.)
Ni	< 100 >	13	0·25	< 100 > < 111 >	13 4	0·07 0·05
Sn	< 110 >	10	0·25 (ref. 1)		5	0·05 (ref. 9)

The material used for these experiments was 99·965 per cent nickel, the principal impurities being iron and silicon. It has not so far been possible to make measurements of the temperature gradient during growth in the melting apparatus.

Table 1 illustrates some measure of agreement between the results for nickel and the published data for tin and this would suggest that essentially the same processes operate during the solidification of the comparatively refractory metal nickel, as for tin.

We thank Prof. E. C. Rollason for provision of the facilities to carry out the work. The provision of a scholarship by W. Canning and Co., Ltd. (R. B.), and general financial assistance by Joseph Lucas, Ltd., are gratefully acknowledged. We also thank the International Nickel Co. (Mond), Ltd., for provision of the stock material.

Effect of Strain-Rate on the Tensile-Yield Stresses of Niobium and Tantalum

IN the course of a systematic study of the mechanical properties of the body-centred cubic transition metals which is now being made in this laboratory, measurements have been made of the effect of strain-rate on the tensile-yield stresses of commercially pure niobium and tantalum. Since these measurements have given interesting results, it is proposed to give a preliminary account of them here.

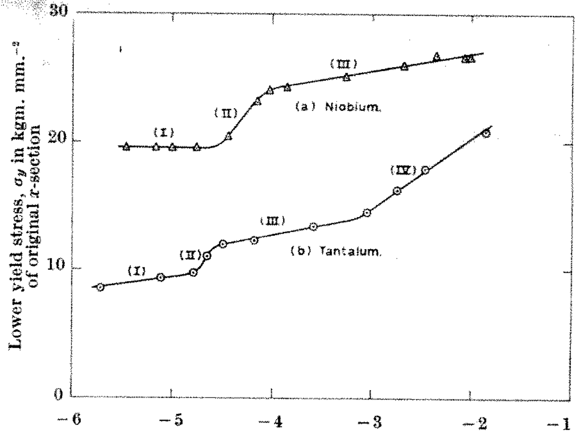

Fig. 1. Effect of strain-rate, $\dot{\varepsilon}$, on the room temperature yield stresses of (*a*) niobium, and (*b*) tantalum

Specimens of average grain diameter about 25μ were prepared from sintered niobium supplied by Murex, Ltd., and tantalum specimens having an average grain diameter of about 400μ from electron beam melted material supplied by the Société Generale de Métallurgie, Hoboken.

Fig. 1 shows the yield stresses of the two materials at room temperature plotted as functions of $\log_{10}\dot{\varepsilon}$, where $\dot{\varepsilon}$ is the strain-rate in sec.$^{-1}$. In the case of niobium three linear ranges are obtained. In range I ($\dot{\varepsilon} < 2 \times 10^{-5}$ sec.$^{-1}$) the yield stress, σ_y, is independent of strain-rate. In range II, ($\dot{\varepsilon} \approx 2 \times 10^{-5}$ to 1×10^{-4} sec.$^{-1}$), and range III, ($\dot{\varepsilon} > 1 \times 10^{-4}$ sec.$^{-1}$), σ_y and $\dot{\varepsilon}$ are related by the equation:

$$\sigma_y = A + A' \log_{10} \dot{\varepsilon} \qquad (1)$$

the values of A and A' being different in the two ranges. In the case of tantalum there are four linear ranges each having different values of A and A'.

An interpretation of the parameter A' can be developed if it is assumed that, in the strain-rate ranges where equation (1) is obeyed, yielding is controlled by stress aided thermally activated dislocation movements (for example, ref. 1). If the assumptions made in this type of theory are accepted, it can readily be shown that A' is related to the first derivative of the activation enthalpy, $\Delta H(\sigma,T)$, with respect to stress at constant temperature, thus:

$$\left(\frac{\partial \Delta H(\sigma,T)}{\partial \sigma}\right)_T = \frac{kT}{A'} \qquad (2)$$

where k is Boltzmann's constant and T the absolute temperature. The left-hand side of equation (2) is known as the 'activation volume', v^*, for the process and is equal to the product of the burgers vector, b, of a slip dislocation and the area swept out by a dislocation segment during activation.

The values of v^* for ranges II and III in niobium come out to be about $7b^3$ and $51b^3$ respectively. In range I, where σ_y is independent of $\dot{\varepsilon}$, v^* is very large, that is, the deformation is controlled by a mechanism for which thermal activation is unimportant. In the case of tantalum, it seems that thermally activated processes control the deformation in all four strain-rate ranges and v^* has a different value for each. The values are $82b^3$, about $6b^3$, $49b^3$, and $16b^3$, for ranges, I, II, III and IV respectively.

The main importance of these results is that they imply that the mechanism controlling the deformation changes with strain-rate in both metals, there being three different mechanisms in the case of niobium and four in the case of tantalum As the result of earlier experiments, it has been suggested that the yielding of iron[1] and possibly other body-centred cubic transition metals[2] is controlled by the Peierls–Nabarro stress of the lattice It is now apparent that this can be so for at most one strain-rate range in each metal

We thank the U K Atomic Energy Authority and the Central Electricity Generating Board for their financial support One of us (G A S) is also indebted to the Department of Scientific and Industrial Research for the award of a research studentship

RADIOCHEMISTRY

Radium and Fission Product Radioactivity in Thermal Waters

Investigations of the radioactivity of spring waters in Hot Springs National Park, Hot Springs, Arkansas, have been published by Boltwood[1], Schlundt[2], and Kuroda *et al* [3] Particular attention was paid to the radon content, which fluctuated considerably from day to day and from season to season In such waters fission products might be detected, coming from fall-out and from fission of uranium ores

The latter process, for spontaneous fission of uranium, would yield about 8 × 10^{-8} µµc of strontium-89 and -90 activity per litre according to Jonte[4] This is below the present limits of detection If the waters were of meteoric origin, fission-product activity from fall-out could possibly be detected The work described here was performed at the end of 1960 when only long-lived activity from fall-out would still be present, and was in a sense preliminary to later work to be carried out closely following bomb tests Also included is a report on analyses of water from Buie Springs, Marlin, Texas

Samples of water from Buie Springs, and from Display Springs No 1 and No 2 at Hot Springs, Arkansas, were collected in October and November, 1960, and analysed 2-l samples were used for radium determinations 40-l samples were used to search for barium-140, and strontium-89 and -90 fission-product activity The samples were collected 24 months after the atmospheric nuclear test suspension had begun Rain at Fayetteville, Arkansas, in the autumn of 1960 contained no measurable amounts of barium-140 or strontium-89, and about 0 5 µµc /l strontium-90 (Nix, J F , personal communication, 1961)

To measure the radium present in Buie Springs water, inactive barium carrier was added to a water sample, and barium sulphate precipitated This was fused with sodium carbonate, the resulting barium carbonate was washed with large quantities of water and then dissolved in dilute nitric acid Four days later the solution was scavenged with ferric hydroxide, and the precipitate containing radium decay products was counted for β-activity in a gas-flow *CE*-14 Tracerlab counter, having a low background of 1 0 count/min Barium and radium carbonates were precipitated from the filtrate and counted

Radium activities shown in Table 1 were calculated using pitchblende of known uranium content as a standard for radium-226, and Armbrust's[5] relative counting efficiencies for the radium-228 radium-226 chains

Table 1

	Buie Springs	Display Springs No 1	Display Spring No 2
Sampling date	Oct 1960	Nov 4, 1960	Nov 4, 1960
Temperature	64° C	59° C	54° C
*p*H	7 85		
Ca	250	38	38
$SO_4^{=}$ p p m	> 100		
^{89}Sr (µµc /l)		none	none
^{90}Sr (µµc /l)		< 0 12	< 0 2
^{140}Ba (µµc /l)		< 0 07	< 0 005
^{226}Ra (µµc /l)	12 ± 1	3 0 ± 0 5	1 2 ± 0 3
^{228}Ra (µµc /l)	2 1 ± 0 4	none	none

Figs 1 and 2 show the activity of the ferric hydroxide fraction and the barium fraction activity respectively The activity in Fig 1 appears to have a 6 1-hr half-life and may be attributed to actinium-228 Because this activity was less than 2 counts/min and was short-lived, counting accuracy was only within 15–20 per cent

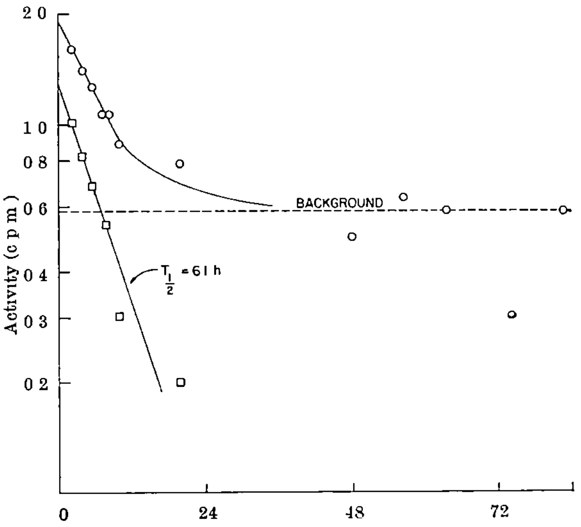

Fig 1 Ferric hydroxide fraction containing radium daughters Buie Springs, Texas ○, Observed counting-rate, □, counting-rate corrected for background

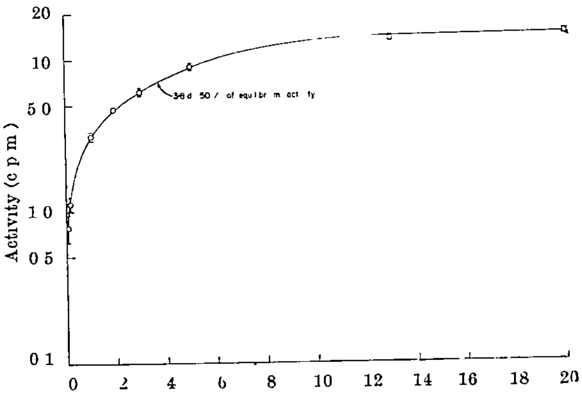

Fig 2 Radium and barium carbonates Buie Springs Texas

Fifty per cent of the equilibrium activity in Fig 2 had grown in 3 8 days, suggesting that radium-226 was present and decaying to ^{222}Rn ($T_{1/2}$ = 3 8 days) In turn the latter decayed to 26 8 m lead-214 and 19 7 m bismuth-214 β-emitters They contributed to the activity in Fig 2, but do not appear in Fig 1. for they had largely decayed away by the time counting was begun

To samples of water from Hot Springs inactive strontium and barium carriers were added, and enough disodium ethylenediamine tetraacetate was added to complex 90 per cent of the calcium present, before precipitating carbonates, to prevent spuriously high strontium yields Further calcium–strontium separation was accomplished satisfactorily by repeated precipitations of strontium in fuming nitric acid After counting the final strontium precipitate (as carbonate) for several weeks to establish that no strontium-89 was observed, strontium-90 was determined by ferric hydroxide scavenging for the yttrium-90 daughter Barium carbonate was counted several weeks, and then scavenged with lanthanum hydroxide to collect any lanthanum-140 and radium daughters

Only short-lived (< 35 min) β-activity was found in lanthanum hydroxide scavengings of water from both hot springs, and the radium parent indicated is radium-226 Radium daughter activities co-precipitated with lanthanum hydroxide would eclipse the low amount of lanthanum-140 that might be present Therefore an upper limit for barium-140 is reported in Table 1, although none was observed

The activity observed for the ferric hydroxide fraction at t_0 was 0 3 c p m above background, and from such poor statistics only an upper limit for strontium-90 in the hot springs could be set It is quite possible that all the activity was in reality due to radium contamination of the strontium precipitate

I thank Prof P K Kuroda for his advice This work was made possible by the support of the U S Atomic Energy Commission

CHEMISTRY

Formation of Alumina from a 'Hydrogen' Alunite

In a process for making pure alumina which is being investigated by us[1], the intermediate product is a basic aluminium sulphate, averaging 39 5 per cent alumina, 40 5 per cent sulphur trioxide and 20 per cent water This material is isomorphous with the alunite series, giving an X-ray diffraction pattern almost identical with the potassium and sodium compounds, all having the general formula R_2O, $3Al_2O_3$, $4SO_3$, $6H_2O$

However, basic aluminium sulphate differs from its alkali-metal analogues in that it can be converted to alumina by calcination at any temperature above 1,000° C and requires no further purification to remove contaminants such as potassium sulphate and sodium sulphate

At lower temperatures in the range 600°–800° C the basic aluminium sulphate is converted to an amorphous material having the approximate formula $3Al_2O_3$, $4SO_3$ The dehydrated basic aluminium sulphate is much more easily dissolved than the starting material and it is possible to make very basic solutions of aluminium sulphate simply by boiling dehydrated basic aluminium sulphate for 15–30 min with a small amount of dilute sulphuric acid[2]

In the temperature-range 750°–950° C dehydrated basic aluminium sulphate loses sulphur trioxide (in two equal and distinct stages), and recrystallizes to form eta-alumina containing only 2–4 per cent of residual sulphur trioxide The rate of decomposition depends on temperature and bed depth, but with a thin bed (1–2 mm) conversion to eta-alumina is substantially completed within 10 min at 900° C

Eta-alumina is normally prepared by the dehydration of beta-alumina trihydrate at temperatures as low as 300° C [3] At higher temperatures (900°–1,000° C) it transforms to theta-alumina and only reverts to alpha-alumina (the final product) at 1,150° C

It is interesting to note, however, that we have been unable to detect theta-alumina during the further calcination of eta-alumina prepared from basic aluminium sulphate After 1 hr at 1,000° C the X-ray powder diffraction pattern shows only alpha-alumina and residual eta-alumina We believe therefore, that residual sulphur trioxide (0 7 per cent at 1,000° C) tends to encourage in some way the direct conversion of eta-alumina to the alpha form Conversely, it is thought possible that residual sodium (approximately 0 3 per cent sodium monoxide) favours the intermediate transition to theta-alumina when the starting material has been prepared as usual from sodium aluminate solutions

Ancient Iron Nails well preserved from Apparently Corrosive Soils

Some years ago, an examination was made in this Laboratory[1] of samples of well-preserved iron objects of Roman origin discovered at Hungate, York A tentative explanation was given for the absence of corrosion, based on the detection in the surrounding soil of traces of phosphates and tannins and on the presence of a coating of mixed ferrous and ferric phosphates on the objects themselves It was suggested that the tannins were inhibitory of the activity of sulphate-reducing bacteria, which would otherwise have been expected to cause severe corrosion of iron in the anaerobic conditions maintaining It was also considered that the phosphate coating alone would probably not provide sufficient protection against corrosion over such a long period (2,000 years), because it is known that industrially produced phosphate coatings are not, in themselves, usually effective in preventing corrosion completely More recent work[2] has shown, however, that sulphate-reducing bacteria are not rendered inactive unless the concentration of tannin reaches a value of about 5 per cent, far in excess of the traces reported in the soils from York It is necessary, therefore, to look for another cause of the protection of the iron

We have now had an opportunity for some further study of the phenomenon In 1961, a number of very well preserved iron nails of early sixteenth century origin were found in silty gravel on an archæological site at St. Neots, Huntingdonshire Chemical and microbiological examination of the soil showed that it contained sulphide and that sulphate-reducing bacteria were active Such a soil would be expected to be highly aggressive to iron

The nails themselves were of a fairly pure iron and carried a highly adherent grey-black coating about 0 5 mm in thickness A transverse section showed that the coating was very coherent and uniform and that a sharp demarcation existed between the coating and the underlying metal Examination of the coating by X-ray diffraction showed it to consist mainly of ferrous phosphate (vivianite), but with a proportion of other material the nature of which we were unable to determine Significantly, we could not detect any oxides, hydroxides, sulphides, chlorides, sulphates or other phosphates of iron Some oxidation of the outer surface of the coating occurred, however, when the nails were left for some weeks exposed to the laboratory atmosphere

We have obtained electrochemical polarization curves for the nails in anaerobic microbiological medium and compared them with similar curves obtained for mild steel in similar conditions

Cathodic polarization curves were similar in the two cases, giving Tafel slopes of about − 165 mV , but the curves for the nails were about 270 mV more positive throughout their length The nature of the cathodic reaction on the coated nails is not known, but must be possible at the open circuit potential of the nails (− 170 mV E_H) in the absence of oxygen Hydrogen evolution would therefore seem to be excluded

The anodic polarization curves differed strikingly For bare mild steel, a Tafel slope of 37 mV was obtained, in close agreement with the value obtained in like conditions by other workers[3] For the nails, however, in addition to the displacement to more noble potentials, the anodic polarization curves gave a Tafel slope of 200 mV This great increase in slope is typical of anodic behaviour of metals in solutions giving anodic films It can be interpreted as a restriction of the passage of ferrous ions from the metal into solution, through the coating, far in excess of that imposed by an artificially prepared phosphate coating It is clear that this natural phosphate coating has features that require further investigation

A more detailed account of these investigations will be presented elsewhere[4]

Borides of Ruthenium, Osmium and Iridium

Buddery and Welch[1] have published approximate compositions for a number of intermediate phases in binary system of boron with the platinum metals The phases were identified by X-ray powder techniques, but crystallographical data were given only for a few of them During the past decade the crystal structures of a number of binary platinum metal borides have been determined, and in Table 1 we have tentatively tried to identify the phases originally reported by Buddery and Welch with the more completely characterized intermediate phases in the ruthenium–boron, osmium–boron and iridium–boron systems

The composition of the various phases as given in Table 1 is only approximate It has been arrived at by examining the powder photographs of arc-melted alloys for each of which only the nominal composition was known The formula for the most boron-rich phase in each system, namely, $RuB_{\sim 2\ 1}$, $OsB_{\sim 2\ 2}$ and $IrB_{\sim 1\ 5}$, corresponds to a metal-rich composition in the homogeneity-range the extent of which is unknown Ru_7B_3 and $Ru_{11}B_8$ appear to have a composition closely corresponding to the ideal structural formula Whether or not this is the case for the more boron-rich phases is uncertain and, besides, it seems largely a matter of opinion which 'ideal structural formula' one prefers to assign to these phases

Table 1 CRYSTALLOGRAPHIC CONSTANTS FOR BORIDES OF RUTHENIUM, OSMIUM AND IRIDIUM

Approximate composition	Structure type	Lattice parameters (Å.)	Ref	Notation according to Buddery and Welch (ref 1)
Ru_7B_3	Th_7Fe_3	$a = 7\ 46_9$, $c = 4\ 71_8$	2	Ru_2B
$Ru_{11}B_8$		$a = 11\ 61$, $b = 11\ 34$, $c = 2\ 83_6$	3	
$RuB_{\sim 1\ 1}$	AlB_2 or WC	$a = 2\ 852$, $c = 2\ 855$	4	RuB
$RuB_{\sim 1\ 5}$	W_2B_5	$a = 2\ 89$, $c = 12\ 81$	4	Ru_2B_3
$RuB_{\sim 2\ 1}$		$a = 4\ 645$, $b = 2\ 865$, $c = 4\ 045$		RuB_2
$OsB_{\sim 1\ 2}$	AlB_2 or WC	$a = 2\ 876$, $c = 2\ 871$	4	OsB
$OsB_{\sim 1\ 6}$	W_2B_5	$a = 2\ 91$, $c = 12\ 91$	4	OsB_2
$OsB_{\sim 2\ 2}$		$a = 4\ 684$, $b = 2\ 872$, $c = 4\ 096$		OsB_2-
$IrB_{\sim 1\ 1}$	α-$ThSi_2$	$a = 2\ 810$, $c = 10\ 26_3$	5	IrB
$IrB_{\sim 1\ 5}$		$a = 10\ 52_6$, $b = 2\ 910$, $c = 6\ 099$, $\beta = 91°$		IrB_2

The phases here referred to as $RuB_{\sim 1\ 1}$ and $OsB_{\sim 1\ 2}$ were tentatively indexed as cubic by Buddery and Welch[1] However, these borides are evidently identical with the AlB_2-type phases which Kempter and Fries[4] recently reported The earlier cubic indexing of these hexagonal phases depends on the c/a ratio being very close to unity Kempter and Fries[4], who prepared ruthenium–boron and osmium–boron alloys by sintering on BN-disks, do not report any deviation from the composition MeB_2, while the observations by Buddery and Welch[1] as well as ourselves indicate a considerable deviation from this composition A more thorough investigation into this problem is being undertaken at this Institute When more precise data are available it will be possible to decide whether these phases should be regarded as crystallizing in the AlB_2- or the WC-type structure

We have confirmed the results of Kempter and Fries[4] that there are phases with the W_2B_5-type structure in the ruthenium–boron and osmium–boron systems and that the boron content of these phases is smaller than 71 4 atomic per cent (Me_2B_5) This formula applies if boron atoms completely occupy the four crystallographical positions in which they can be located without unreasonably short interatomic distances being formed It has not yet been determined experimentally to what extent these possible boron positions are actually occupied in the various phases possessing the same arrangement of metal atoms as W_2B_5 The phases $RuB_{\sim 2 1}$ and $OsB_{\sim 2 2}$ are very probably identical with RuB_2 and OsB_{2+} reported by Buddery and Welch[1] as well as with the phases observed by Kempter and Fries[4] in alloys containing 71 atomic per cent boron These isomorphous phases have an orthorhombic structure the most probable space-group being *Pmmn* The metal atoms are located at 2(*a*) with $z_{Ru} = 0\ 1508$ and $z_{Os} = 0\ 1535$, respectively (The centre of symmetry has been chosen as origin) There is strong experimental evidence that boron atoms occupy a 4(*f*) position with the approximate co-ordinates $x_B = 0\ 059$, $z_B = 0\ 639$ in $RuB_{\sim 2 1}$, and $x_B = 0\ 058$, $z_B = 0\ 632$ in $OsB_{\sim 2 2}$ Considerations of the space available indicate that boron atoms can also be located at 2(*b*) ($z \sim 0\ 8$), but, for the crystals studied, the difference syntheses did not display significant maxima at this position It is not possible to decide to what extent boron atoms may occupy a 2(*b*) position in these phases until very accurate investigations of the homogeneity ranges as well as of the crystal structures have been undertaken

The most boron-rich intermediate phase observed in arc-melted iridium–boron alloys has a composition approximating to $IrB_{\sim 1 5}$ It has a monoclinic structure for which the most probable space-group is *C* 2/*m* The iridium atoms occupy two sets of 4(*i*) positions with the co-ordinates $x_I = 0\ 0995$, $z_I = 0\ 1388$, $x_{II} = 0\ 3576$, $z_{II} = 0\ 2885$ Space considerations indicate that boron atoms can be located in four sets of 4(*i*)-positions All the possible boron positions correspond to positive regions in the electron density difference synthesis, where the contribution of the iridium atoms has been subtracted The approximate co-ordinates of the positions as derived from the difference synthesis are as follows

$x_{III} = 0\ 553$ $z_{III} = 0\ 388$
$x_{IV} = 0\ 180$ $z_{IV} = 0\ 465$
$x_V = 0\ 712$ $z_V = 0\ 309$
$x_{VI} = 0\ 754$ $z_{VI} = 0\ 069$

Complete occupation by boron atoms of the positions V and VI would imply some very short iridium–boron and boron–boron contacts in the structure It would not be incompatible with the experimental results to assume that one or both of these positions are only partly occupied but, as yet, no firm conclusion can be reached on this point

We thank Prof G Hagg for his kind interest This work was financially supported by the Swedish Natural Science Research Council and the Air Force Office of Scientific Research, OAR, through the European Office, Aerospace Research, U S Air Force, under contract *AF* 61(052)–40

Determination of Polyunsaturated Fatty Acids in *Hevea* Latex

The unsaturated fatty acids expected to be present in *Hevea* latex are very probably oleic, linoleic and linolenic Altman[1], using a method as described by Hazura, succeeded in showing the presence of oleic and linoleic acid in this latex According to this method the unsaturated fatty acids are oxidized by alkaline potassium permanganate solution, converting them to the corresponding oxyacids Altman could identify the dioxystearic acid (m p 131°) and sativic acid (m p 175°)

When the fatty acids mixture consists of saturated fatty acids, oleic and linoleic acid, the method as described by Bertram[2] is applicable These methods are based mainly on the addition of substances, namely, iodine, bromine, etc , to the double bonds, and are indirect, thus making the results not always trustworthy Determination of a mixture of unsaturated fatty acids comprising those having more than three double bonds is more difficult

At present spectrophotometric methods[3] are used to determine the composition of fatty acids mixtures These methods are based on the observation by Moore that linoleic and linolenic acids are isomerized in an alcoholic alkali solution to a conjugated system of double bonds that gives an absorption in the ultraviolet region The Spectroscopy Committee[4] reported extensively on the spectrophotometric method for the determination of polyunsaturated fatty acids by alkali isomerization Equations for the calculation of the polyenoic acid contents were given Micromethods were developed by Hammond and Lundberg[5], Herb and Riemenschneider[6] and Holman and Hayes[7] A method essentially similar to that described by Herb and Riemenschneider has been used by me for the determination of polyunsaturated fatty acids in *Hevea* latex

The reaction vessels used were as proposed by Herb and Riemenschneider and made of 'Pyrex' tubes The vessels have caps with ground joints and are provided with nitrogen gas inlet tubes The lower parts of the vessels had an inner diameter of 16 mm A Beckman model *DU* spectrophotometer equipped with a hydrogen lamp was used for the measurement of the ultra-violet spectra of the samples before and after isomerization The absorbancies were measured in matched quartz cells which had a light path of 2 0 cm The constant-temperature apparatus consisted of an oil bath heated by an electric hot plate and maintained at 180 ± 0 5° C by a Sunvic regulator

The lipids were extracted by adding fresh latex dropwise with mechanical stirring to 2 volumes of 96 per cent ethyl alcohol, previously warmed to a temperature of 40° C , and filtered on a Buchner funnel The coagulum was next re-extracted twice with alcohol at 40° C for 1 hr During the extraction carbon dioxide was bubbled through the solution and 1 c c of 0 1 per cent hydroquinone solution was added per 100 dry rubber content The yellow-coloured alcohol extracts were combined and evaporated to a small volume under reduced pressure and atmosphere of carbon dioxide at a temperature of below 50° C The aqueous residue was extracted 3 times with light petroleum ether (b p 40–60° C), at a volume ratio of 1 8 The combined petroleum ether extracts were washed 5 times with small volumes of distilled water and dried with anhydrous sodium sulphate After filtration, the dried extract was evaporated to dryness at atmospheric pressure and next the remaining solvent was removed at reduced pressure

For the analysis the lipid material was dissolved in light petroleum ether (40°–60° C) and made up to volume A number of ml of the solution were transferred to the reaction vessels and the petroleum ether evaporated under nitrogen 11 gm of ethylene glycol–potassium hydroxide reagent were added, the contents mixed by shaking and for 15 min nitrogen was led in (in later experiments 5 gm of the reagent were used) A vessel containing only the reagent served as blank The vessels were then placed in the oil bath maintained at 180° C After being heated for exactly 15 min , the vessels were chilled in water The reaction mixture was diluted with absolute methanol and made up to volume Absorbancies of these solutions were measured at 233, 268, 315, 346 and 374 mμ against the blank

For the measurement of the absorption before isomerization the lipid material was dissolved in iso-octane or absolute methanol A ten-fold dilution was usually necessary for the determination of the absorbancy at 233 mμ The blank consisted of iso-octane or absolute methanol

The extinction coefficients of the sample before and after isomerization are calculated

$$k_b = \frac{A}{l\ c} \text{ and } k_i = \frac{A}{l\ c}$$

c is expressed as gm lipids per 1 solution The differences, $k = k_i - k_b$, at 233, 268, 315 and 346 mμ are substituted in the following equations

Percentage of dienoic acid $= 1\ 092\ k_{233} - 0\ 573\ k_{268} - 0\ 259\ k_{315} + 0\ 021\ k_{346}$

Percentage of trienoic acid $= 1\ 105\ k_{268} - 0\ 879\ k_{315} + 0\ 306\ k_{346}$

Percentage of tetraenoic acid $= 1\ 650\ k_{315} - 1\ 555\ k_{346}$

Percentage of pentaenoic acid $= 1\ 144\ k_{346}$

Latex tapped from several *Hevea* clones was used for the present investigation In Table 1 the polyunsaturated acids contents of *Hevea* latex are listed The standard deviations of the calculated values are also given

Table 1 POLYUNSATURATED ACIDS CONTENT OF *Hevea* LATEX, TOTAL LIPIDS (PER CENT)

Sample	Pentaene	Tetraene	Triene	Diene	No of determinations
PB 186	0 14 ± 0 09	0 50 ± 0 16	1 75 ± 0 21	22 76 ± 3 23	5
Tjir 16	0 56 ± 0 35	0 88 ± 0 14	1 95 ± 0 90	14 62 ± 0 10	3
Tjir 1	0 14	0 32	2 90	19 08	1
PR 162	0 18	0 37	1 77	8 04	1
Pilm B 84	0 84	0 22	10 04	61 26	1
Av 385	—	—	0 23	11 46	1
Mixed clonal	—	0 83	1 80	17 24	1

It is noteworthy that the polyunsaturated acids content of *PB* 186 are significantly different from those of *Tjir* 16, with the exception of trienoic acid (0 05 > *P* > 0 02) It is further interesting to note that the clone *Pilm B* 84 has an exceptionally high dienoic acid content The findings clearly show that the polyenoic acids contents of *Hevea* latex vary with the clone from which the latex is obtained

I thank Miss Liem Jan Ing for her assistance in the experimental work and Miss Tan Jan Nio for computing the results

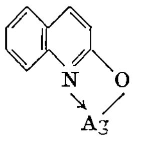
Silver (I) Complexes with 2-Quinolinol and 4-Methyl-2-Quinolinol : a Possible 4-Membered Ring Chelate System

ALTHOUGH the silver (I) complexes of 8-quinolinol (8-hydroxyquinoline) have been the subject of several investigations[1–4], little is known about the complexes formed with 2-quinolinol and its derivatives The 8-quinolinol complexes of silver are rather unusual in that two chelating groups, per metal ion, are present in the complex, or $Ag(C_9H_6NO)\ C_9H_6NOH$ To complicate matters, both a yellow and a green form of the above are known However, we have recently shown that the green form is identical to the yellow except that it contains a small amount of free silver[5] With the above information available, it was thought that the silver (I) 2-quinolinol complexes would be similar to those of 8-quinolinol

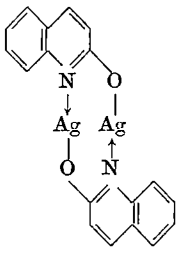
It was found, however, that the composition of the 2-quinolinol complex corresponded to a 1 1 formula, or $Ag(C_9H_6NO)$, rather than a 1 2 composition The complexes were prepared as follows approximately 1 2 gm of silver acetate was dissolved in 250 ml of water, heating the mixture to effect solution The solution was cooled to about 60° C , buffered with 1 gm of sodium acetate, and then 1 gm of 2-quinolinol or 4-methyl-2-quinolinol dissolved in about 30 ml of 95 per cent ethyl alcohol was added Immediately on mixing, a white flocculent precipitate of the silver complex was formed The mixture was then digested for about 30 min on a steam bath After digestion, the precipitate was filtered off, washed several times with water, and then dried in a vacuum desiccator for 24 hr The yield, based on silver ion present, was not quantitative, but averaged about 45 per cent Analysis of the complexes gave $Ag(C_9H_6NO)$, Ag 42 80 per cent theor , 42 10 per cent found, N, 5 56 per cent theor , 5 37 per cent found, $Ag(C_9H_5NOCH_3)$, Ag 40 55 per cent theor , 40 58 per cent found, N 5 27 per cent theor , 5 23 per cent found The silver contents were determined by ignition of the complexes at 800° C , the nitrogen contents by the Dumas method as determined by the Schwarzkopf Laboratory, Woodside, New York

The thermal properties of the complexes were studied by thermogravimetric analysis and differential thermal analysis Both complexes exhibited similar thermogravimetric analysis curves in that they began to lose weight at about 300° C The silver residue weight-levels were obtained at about 700° C The differential thermal analysis thermograms revealed that the decomposition reactions were exothermic as evidenced by a single sharp exothermic peak at 275° and 300° C., for the 4-methyl- and 2-quinolinol chelates, respectively.

It was not possible to determine the molecular weight of either complex due to their insolubility in all the common organic solvents. However, it is of interest to speculate as to their possible structures.



(I)



(II)

Structure (I) would be unique in that a 4-membered ring chelate system is present. This type of ring system is rather rare, with the exception of carbonatoamminecobalt (III) complexes[6]. Recent investigations have shown that the copper 1,3-diphenyltriazen complexes[7] and copper acetate 1-hydrate[8,9] are binuclear structures, and do not involve 4-membered ring chelate systems.

The dimer, as shown in structure (II), is also possible due to the *sp* hybridization of Ag (I) to form linear complexes such as $[H_3N\rightarrow Ag\leftarrow NH_3]^+$. At the present time it is not possible to differentiate between these two possible structures.

Assignment of *cis–trans* Configuration to 1,2-Dialkyl*cyclo*hexanes

PREVIOUS work carried out at the Mass Spectrometry Centre of the University of Liège has shown the specific behaviour under electron impact of *cis* and *trans* isomers in a series of pairs of cyclanic stereoisomers. It has been especially pointed out in 1,2-dialkyl derivatives of *cyclo*propane[1], *cyclo*butane[2], *cyclo*pentane[3] and *cyclo*hexane[4] that in the ionized state the *cis* isomer is less stable than the corresponding *trans* isomer (that is, the relative abundance, expressed as a fraction of total ionic current for 70 V energy electrons, of molecular ions of a *cis* isomer is smaller than that for the corresponding *trans* molecule).

This observation being quite general for the 15 pairs investigated in the works cited gives a rule enabling the *cis–trans* assignment on the basis of the mass spectra in the case of cyclanic stereoisomers for which the assignment has not yet been done.

In 1959 the National Bureau of Standards[5] published mass spectral data for 8 pairs of *cyclo*hexane isomers disubstituted in position 1 by a *cyclo*hexyl or methylene*cyclo*hexyl group and in position 2 by a methyl, ethyl, propyl or butyl group. Those isomers were characterized by their relative boiling points, that is to say one of them was labelled 'high boiling' and the other 'low boiling'. For each isomer of each of those 8 pairs we calculated the abundance of the molecular ions in percentage of total ionization. The results are presented in Table 1.

Table 1. RELATIVE ABUNDANCES OF MOLECULAR IONS IN SEVERAL 1,2-DIALKYL*cyclo*HEXANES (PERCENTAGE OF TOTAL IONIC CURRENT)

Pair No.	Nature of alkyl group		Abundance in low boiling isomer	Abundance in high boiling isomer
1	$—CH_3$	$—$*cyclo*C_6H_{11}	2.33	1.01
2	$—C_2H_5$	$—$*cyclo*C_6H_{11}	1.54	0.66
3	$—nC_3H_7$	$—$*cyclo*C_6H_{11}	1.24	0.51
4	$—iC_3H_7$	$—$*cyclo*C_6H_{11}	0.49	0.08
5	$—nC_4H_9$	$—$*cyclo*C_6H_{11}	1.03	0.42
6	$—iC_4H_9$	$—$*cyclo*C_6H_{11}	0.95	0.41
7	$—CH_3$	$—CH_2—$*cyclo*C_6H_{11}	3.35	2.00
8	$—C_2H_5$	$—CH_2—$*cyclo*C_6H_{11}	1.60	1.02

This shows that molecular ions of so-called 'high boiling' isomers are all less abundant than those of the corresponding so-called 'low boiling' isomers. Referring to the preceding results concerning the 1,2-dialkyl*cyclo*alkanes, as mentioned previously, I suggest, in the present cases, attributing the *cis* structure to the isomers for which the molecular ions are the least abundant and the *trans* structure to the corresponding isomers for which the molecular ions are the most abundant.

This conclusion agrees very well with the *cis–trans* assignment of the isomers already investigated. In the 1,2-disubstituted derivatives of *cyclo*propane, *cyclo*butane, *cyclo*pentane and *cyclo*hexane, the *cis* isomer is always the high boiling one, as has been shown by experimental[6,7] and theoretical[8,9] investigation.

I thank Prof. L. D'Or for his advice.

BIOCHEMISTRY

Adaptation of the Small Intestine to a High-Fat Diet containing Saturated and Unsaturated Fatty Acids

THE role of exogenous fat is generally evaluated with regard to its caloric value, digestion, deposition, etc. It was, however, revealed that it is of great importance whether or not the fatty component of the diet contains saturated or unsaturated fatty acids.

Marked differences as regards the influence exerted by these substances can be observed, for example, when investigating the weight-curves of realimented

Table 1 CHANGES OF THE SMALL INTESTINE IN RATS AFTER THE ADMINISTRATION OF DIFFERENT HIGH-FAT DIETS

	Stock diet* (controls)	High-fat diet† fatty acids	
		Saturated	Unsaturated
Small intestine (mean values)			
Length (cm)	114 4^{a}	141 3^{a}	130 0^{bb}
Fresh weight (gm)	5 43^{a}	9 49^{a}	6 16^{cc}
Dry weight (gm)	1 26^{b}	1 91^{b}	1 39^{dd}
Protein (gm)	0 86^{a}	1 29^{b}	0 90^{dd}
Enzyme activity (per length unit controls = 100 per cent)			
Peptidases	100^{a}	132^{b}	108^{dd}
Lipase	100^{a}	129^{d}	116^{dd}
Amylase	100^{a}	43^{d}	29^{aa}
Weight of animals (mean)			
At beginning of experiment (gm)	282 4^{d}	287 3^{d}	286 7^{dd}
After 6 days of starvation	222 8^{d}	229 9^{d}	229 2^{dd}
After 17 days of realimentation (at time of decapitation)	306 1^{a}	268 5^{a}	298 4^{dd}

* Composition of stock diet 25 cal. per cent of protein, 22 cal per cent of carbohydrates, 53 cal per cent of fat.

† Composition of high-fat diets 15 cal per cent of protein, 15 cal per cent of carbohydrates, 70 cal per cent of fat, 60 cal per cent of the fat was formed by chemically pure fatty acids, 10 cal per cent of the fat was mostly invisible fat (wheat germ, fatty milk and cod liver oil, etc) Saturated fatty acids = palmitic acid, unsaturated fatty acids = *cis*-isomers of ethylesters linoleic acid (56 per cent), linolenic acid (17 per cent) and oleic acid (27 per cent).

Statistical evaluation

^{a} Controls saturated fatty acids or saturated fatty acids unsaturates fatty acids
^{aa} Controls unsaturated fatty acids $P < 0\ 001$
^{b} ^{bb} ,, ,, ,, ,, $0\ 01 > P > 0\ 001$
^{c} ^{cc} ,, , ,, ,, $0\ 05 > P > 0\ 01$
^{d} ^{dd} ,, ,, ,, , not significant

animals While the high-fat diet containing unsaturated fatty acids renders an optimal course for the possible weight-curve and a similar intake of food as on a stock diet, the administration of saturated fatty acids in a high-fat diet of similar composition led to a significant retardation of the weight-curve The intake of food under these conditions was approximately 25 per cent higher The lipid balance was more positive when the diet contained saturated fatty acids[1]

To elucidate these findings in experimental animals the morphology and some functions of the small intestine, the main active absorption surface of the animal, were investigated

White male albino rats of the Wistar strain were realimented after starvation for 6 days on a standard diet and another group on an isocaloric high-fat diet containing either saturated or unsaturated fatty acids Each group comprised 10–20 animals

Following realimentation, the animals were killed by decapitation, after the organs of the alimentary tract had been removed the length of the small intestine was measured (suspended with a 5-gm weight), and after rinsing its fresh weight was determined Next the dry matter content and protein content of the tissue were estimated The activity of the following enzymes was investigated in homogenates prepared from 10-cm long samples of different sections of the small intestine peptidases (substrate, 1-leucyl-glycyl-glycine[2]), lipase (substrate, tributyrin[3]) and amylase (substrate, starch[4]) The results are presented in Table 1

From the findings, it appears that during short-term realimentation of rats with a high-fat diet morphological and functional changes of organs of the digestive tract occur, particularly of the small intestine, its length increases, which is not due to mere atonia, but hypertrophy or hyperplasia, as indicated by the values for dry matter, the content of protein and the activity of peptidase The lipolytic and amylolytic activity changes, there being an adaptation to the high-fat content of the diet After the high-fat diet containing unsaturated fatty acids the changes described here are less marked

When interpreting these changes the volume and composition of the diets must be considered in particular As to the volume, it was equal in all three types of diets (94, 97, 97 c c /100 gm respectively) In animals on a diet containing saturated fatty acids the increased volume of the ingested food may take part in the morphological changes A significant part is, however, also played by the composition of the diet as these changes occurred also in animals on the diet containing unsaturated fatty acids, where the volume of the ingested food was practically equal to the controls Similar morphological changes were also recorded so far as the fresh weight and dry matter content of the stomach and the large intestine are concerned

These findings indicate that on a high-fat diet under the experimental conditions described morphological and functional adaptations of the organs of the digestive tract occur, and are induced not only by the volume, but also by the composition of the diet The influence of saturated fatty acids is in this respect more marked than that of unsaturated ones

Effect of Fatty Acids, Ketone Bodies, Diabetes and Starvation on Pyruvate Metabolism in Rat Heart and Diaphragm Muscle

IN alloxan diabetes the uptake and oxidation of pyruvate *in vitro* by rat ventricle muscle slices[1] and diaphragm muscle[2] is impaired, and the output of lactate may be increased Moreover, in alloxan diabetic rats[3] the blood concentration of pyruvate may be increased, and in dogs treated with growth hormone pyruvate tolerance is impaired and blood pyruvate elevated[4] In earlier experiments[5], evidence was obtained that impaired phosphorylation of glucose and of fructose-6-phosphate in hearts from alloxan diabetic or starved rats could result from enhanced respiration of fatty acids and ketone bodies and the suggestion was made that this might also be responsible for the high glycogen concentration of the heart in diabetes and starvation and for the myoglycostatic effect of growth hormone In view of these findings, it seemed important to investigate the possibility that enhanced respiration of fatty acids and ketone bodies might also be responsible for abnormalities of pyruvate metabolism in muscles of alloxan diabetic rats and in animals treated with growth hormone

Hearts from male albino Wistar rats weighing 200–260 gm (injected beforehand with 12 mgm 'Nembutal' and 2,500 units heparin intraperitoneally) were perfused for 15 min by recirculation[6] with medium containing (where pyruvate uptake was measured) sodium pyruvate ± fatty acids or ketone bodies or (where pyruvate and lactate production from glucose was measured) glucose and insulin In experiments with palmitate the medium contained, in addition, 2 per cent bovine plasma albumin (Armour Fraction V) freed of insulin and insulin antagonists by passage through Whatman cellulose powder as a 4 per cent solution in phosphate borate buffer *p*H 8 4 (ref 7) followed by dialysis and freeze-drying, and freed of fatty acids by two extractions with heptane glacial acetic acid (20 1 v/v) followed by drying *in vacuo* and dialysis against two changes of 0 9 per cent sodium chloride and six changes of distilled water (ten-fold excess) and freeze-dried Solutions of albumin ± 0 75 m*M* palmitate in perfusion medium were dialysed overnight against a twenty-fold excess of the latter before use Uptake of glucose by the heart was measured by methods given elsewhere[6], pyruvate and lactate were assayed in perfusion medium with lactate dehydrogenase[8] Hemidiaphragms from female albino Wistar rats of 100–150 gm were incubated for 60 min in 2 ml of medium containing pyruvate (± 2-[^{14}C]pyruvate) with or without fatty acids In experiments with palmitate (0 6 m*M*) the medium contained in addition 0 85 per cent bovine plasma albumin $^{14}CO_2$ generated by diaphragm muscle was collected (following addition of sulphuric acid to 1 4 *N*) in *M* hyamine in methanol, and assayed for radioactivity in a Tricarb liquid scintillation counter with addition of 0 4 per cent 2,5-diphenyloxazole and 0 05 per cent 1,4-*bis*-2-(5-phenyloxazolyl)-benzene in toluene[9] Rats were made diabetic by alloxan (60 mgm /kgm) injected into a tail vein and used 48 hr later Starved rats were deprived of food for 40–48 hr , control and diabetic rats were not deprived of food

The uptake of pyruvate by hearts from normal rats perfused with medium containing 4 m*M* pyruvate (µmoles/gm tissue/hr , mean ± *S E* , number of hearts perfused in each group in parenthesis) was significantly reduced by 5 5 m*M* DL-β-hydroxybutyrate from 162 ± 1 to 111 ± 7 6 (14), and by 5 5 m*M* aceto-acetate from 158 ± 17 6 to 78 ± 12 4 (6), and by 2 8 m*M* *n*-octanoate from 181 ± 14 to 84 ± 9 2 (6) Lactate production was not significantly altered by these substrates (the respective changes were 94 ± 5 2 to 108 ± 4 4, 61 3 ± 3 to 68 ± 2 7, and 81 ± 4 2 to 78 ± 6 1) In hearts perfused with medium containing 2 per cent bovine plasma albumin, pyruvate uptake was significantly reduced by 0 75 m*M* palmitate from 79 ± 2 5 to 57 ± 3 4 (11), and lactate output increased from 49 ± 1 8 to 66 ± 6 4 Hearts from alloxan-diabetic or starved rats perfused with medium containing m*M* pyruvate showed a depressed uptake relative to that of controls (from 78 ± 6 4 to 48 ± 4 8 and 43 ± 2 7 respectively, 6 hearts in each group) whereas lactate output was not significantly altered by diabetes (62 ± 12 to 71 ± 5 1) or starvation (62 ± 12 to 68 ± 7 7) In the absence of added pyruvate, 0 75 m*M* palmitate and 5 5 m*M* DL-β-hydroxybutyrate increased the output of lactate from 8 6 ± 2 3 to 45 ± 8 9 (6) and 8 5 ± 1 8 to 20 3 ± 3 4 (6) respectively, whereas pyruvate output was not significantly altered (3 1 ± 0 72 to 3 8 ± 0 69 and 1 6 ± 0 30 to 1 8 ± 0 15 respectively) Since the rate of glycogen breakdown (and therefore of pyruvate formation from glycogen) was not accelerated by fatty acids or ketone bodies, it is concluded that these substrates must impair the utilization of pyruvate in the heart by some pathway other than conversion to lactate (that is, these substrates are presumed to have impaired oxidation of pyruvate)

In hearts perfused with glucose (1 mgm /ml) and insulin (0 1 unit/ml), uptake of glucose (in µmoles/gm /hr) was impaired by alloxan diabetes, starvation and 2 8 m*M* octanoate from 77 ± 1 7 (14) to 36 ± 1 6 (13), 46 ± 1 7 (13) and 46 ± 1 3 (6) respectively This impairment of glucose uptake has been attributed to inhibition of the hexokinase and phosphofructokinase reactions[5,10,11] Glucose uptake was also reduced by similar mechanisms by 0 75 m*M* palmitate carried by 2 per cent bovine plasma albumin, from 66 ± 1 7 (18) to 43 ± 1 6 (18) In spite of the fact that glucose uptake was impaired (and therefore the formation of pyruvate from glucose was presumably reduced, see ref 5) the combined output of pyruvate and lactate was not diminished by diabetes or starvation (changes from 51 ± 7 to 56 ± 11 and 53 ± 9 respectively), and was increased by octanoate (from 51 ± 7 to 74 ± 9) and palmitate (from 41 ± 2 4 to 52 ± 3 7) The output of pyruvate alone was increased by diabetes and starvation (from 4 8 ± 0 27 to 9 0 ± 1 0 and 11 0 ± 1 1), whereas that of lactate was unchanged (from 46 ± 7 to 47 ± 11 and 42 ± 9) Octanoate and palmitate increased the output of lactate (from 46 ± 7 to 72 ± 9 and from 33 ± 2 4 to 46 ± 3 7 respectively) and reduced that of pyruvate (from 4 8 ± 0 27 to 2 1 ± 0 26 and 7 7 ± 0 62 to 5 9 ± 0 47) The lactate to pyruvate ratio was thus decreased by diabetes and starvation (from 9 6 ± 1 8 to 5 2 ± 0 52 and 3 8 ± 0 40), but increased by octanoate and palmitate (from 9 6 ± 1 8 to 29 1 ± 1 4 and from 4 2 ± 0 43 to 8 0 ± 0 90 respectively) We conclude that in rat heart the utilization of pyruvate formed from glucose (by reactions other than conversion to lactate) is impaired by diabetes and starvation and by fatty acids On the other hand, whereas diabetes and starvation decrease the ratio of lactate to pyruvate in the perfusion medium, fatty acids increase this ratio

When hemidiaphragms from normal fed rats were incubated in the presence of 4 m*M* pyruvate ± 2-[^{14}C]pyruvate (4 mµc /ml), 4 m*M* butyrate reduced the uptake of pyruvate from 29 2 ± 1 to 23 5 ± 0 47 (16), diminished the output of $^{14}CO_2$ by 5,600 ± 1,050 c p m /gm /hr (from a control-level of 14,500) and increased lactate output from 17 3 ± 0 56 to 20 3 ± 0 39 The uptake of pyruvate by hemidiaphragms from diabetic rats fed alloxan was lower than that of hemidiaphragms from normal rats (18 5 ± 1, 8 observations) and only slightly further reduced by 4 m*M* butyrate (16 1 ± 0 4, 8 observations) When hemidiaphragms from rats normally fed were incubated in medium containing 0 85 per cent bovine plasma albumin and m*M* pyruvate ± 2-[^{14}C]pyruvate (3 4 mµc /ml), pyruvate uptake was not significantly changed by 0 6 m*M* palmitate (13 1 ± 0 35 to 12 9 ± 0 42, 8 observations each group), but the output of lactate was increased (from 11 4 ± 0 2 to 14 1 ± 0 61) and $^{14}CO_2$ production was diminished by 470 ± 127 c p m /gm /hr (from a control-level of 6,500) We conclude that in rat diaphragm the uptake of pyruvate is diminished by diabetes and by butyrate, and that diabetes, butyrate and palmitate impair pyruvate oxidation

The present studies have confirmed that the uptake and oxidation of pyruvate by rat heart and diaphragm muscle are impaired in alloxan diabetes They have shown further that similar changes occur in the heart following starvation of the rat, that the utilization of pyruvate formed from glucose is also diminished in the heart by diabetes and starvation, and that similar changes can be induced in hearts and diaphragms of normal rats by the *in vitro* addition of fatty acids and ketone bodies It is suggested, therefore, that these particular changes in pyruvate metabolism in heart and diaphragm muscle in diabetes and starvation are due to enhanced respiration of endogenous fatty acids (and perhaps ketone bodies) The present studies have also shown that the metabolism of pyruvate derived from glucose in hearts from diabetic or starved rats differs in one respect from that of normal hearts perfused with fatty acids In diabetes and starvation, the ratio of lactate to pyruvate in the perfusion medium is decreased, whereas in the normal heart perfused with fatty acids this ratio is increased If, as we suggest, enhanced respiration of fatty acids (and perhaps ketone bodies) were responsible for impaired pyruvate utilization in diabetes and starvation, then some other factor must be responsible for the change in lactate to pyruvate ratio in these conditions One possibility in this connexion is that it is brought about by an increase in the ratio of extramitochondrial NAD to $NADH_2$ Glock and McLean[12] have already shown that the ratio of total NAD to $NADH_2$ is increased in diaphragm muscle in alloxan diabetes In view of these findings it seems likely that enhanced respiration of fatty acids and ketone bodies is also responsible for the high blood pyruvate and impaired pyruvate tolerance observed in dogs treated with growth hormone[4]

We wish to thank the British Diabetic Association, the British Insulin Manufacturers and the Medical Research Council for grants which contributed to the cost of this investigation We thank Prof F G Young for his encouragement

Role of Phagocytosis in the Uptake of Lipid by a Phagocytic Cell

It is well known that free fatty acids are readily taken up by most types of cell, much controversy exists however, concerning uptake of complex lipids It has been recently suggested that triglycerides may enter liver and adipose tissue[1–3] by a phagocytosis-like process The existence of such a mechanism of incorporation of lipid was investigated using suspensions of polymorphonuclear leucocytes capable of phagocytosis *in vitro*

If sequestration of medium represented the chief means of uptake of lipid by such cells a non-selective incorporation might be expected On the other hand, if attachment to the surface of phagocytic cells constitutes a necessary phase in engulfment of particles and macromolecules, incorporation could be selective because of selectivity and competition in attaching to the cell

This communication reports that uptake of lipid by the leucocytes is indeed highly selective, but that sequestration by a phagocytosis-like process does not account for the observed selectivity

Suspensions of polymorphonuclear leucocytes obtained from rabbit peritoneal exudates of rabbits[4] were incubated in the ascitic fluid to which were added one of four kinds of lipids labelled with carbon-14 (1) long-chain fatty acids (as albumin-free fatty acids complexes), (2) triglycerides, (3) mixed phospholipids, biosynthetically prepared by incubating leucocytes with a ^{14}C-1-free fatty acid and subsequent isolation of the radioactive phospholipid fraction of the cell lipids, (4) human chylomicra obtained by thoracic duct cannulation and by feeding a fat meal containing ^{14}C-1-palmitic acid

The radioactivity and lipid content of the total lipid extracts of cells and medium were determined at incubation times of up to 1 hr [5], the appearance of water-soluble radioactivity was sought in the water washings of these total lipid extracts The radioactivity of cell lipid fractions eluted from silicic acid columns was also measured and the $^{14}CO_2$ evolved during incubation was collected in hyamine and counted as described by Isselbacher[6] The effects of inhibition of metabolism on the uptake of lipids by these cells was determined by incubating at 4° C and by exposure to the following agents (*a*) 0 001 *M* sodium iodo-acetate (IAA), (*b*) 0 02 *M* sodium fluoride, (*c*) 0 0025 *M* potassium cyanide, (*d*) 0 0025 *M* 2,4 dinitrophenol (DNP)

In the evaluation of the results a distinction was made between incorporation of medium lipids into the cells by a process dependent on metabolism and a non-metabolic association of radioactive lipid with the leucocytes The following criteria have been viewed as evidence for true metabolic incorporation (1) an increase in the radioactivity of cell lipids during the course of incubation, (2) dependence of uptake of labelled fat on intact metabolism, (3) appearance of increasing amounts of radioactivity as $^{14}CO_2$ and as water-soluble radioactivity which would indicate breakdown of the labelled lipid, (4) appearance of radioactivity into cell lipid fractions other than those in which the label was introduced into the medium

Table 1 shows that incorporation of the carbon-14 label into total lipid extracts of the leucocytes was regularly obtained during incubation with either ^{14}C-1-free fatty acid or with ^{14}C-1-complex lipids added to the ascitic fluid Uptake of ^{14}C-1-free fatty acid was prevented by incubation at 4° C and suppressed by inhibitors of anaerobic glycolysis (IAA and sodium fluoride), these conditions did not affect the uptake of label from ^{14}C-complex lipids Inhibition of oxidative metabolism (with potassium cyanide or DNP) had no suppressive effect on the incorporation of carbon-14 from any of the radioactive substrates Column 2 shows a drop in radioactivity/mgm medium lipids during incubation with ^{14}C-1-free fatty acid, which may be taken to indicate that lipid species other than free fatty acid were taken up more slowly

In addition, following incubation with ^{14}C-free fatty acid, the label also appeared as $^{14}CO_2$ and radioactivity was found in the water washings of the total lipid extracts, however, neither water-soluble radioactivity nor significant amounts of $^{14}CO_2$ could

* The lipid content and composition of the ascitic fluid was not affected by the addition of trace amounts of ^{14}C-1-labelled lipids (free fatty acids triglycerides or phospholipids) In the case of chylomicra, from 200–400 mgm. of fat were added in each experiment to a total volume of 75–150 ml of cell suspension In all experiments, cells and medium were separated by centrifugation The cells were washed with saline to remove adherent or trapped medium and then extracted as previously described (ref 5)

† The results are presented as a percentage of c p m /mgm cell lipid after 60 min incubation at 37° in each experiment and are given as mean ± 1 *S D*

‡ Data shown pertain to ^{14}C-1-linoleic acid, comparable results were obtained with ^{14}C-1-palmitic, stearic and oleic acids

The results shown in column (2) represent the radioactivity found in the medium expressed as a percentage of c p m /mgm medium lipid prior to incubation The figure between parentheses indicates the number of observations

be recovered during incubation with the labelled complex lipids

Table 2 presents the distribution of the carbon-14 label in the lipid fractions of the leucocytes Incubation in the presence of ^{14}C-free fatty acid resulted in the appearance of the label almost exclusively in the phospholipid and triglyceride fractions of the cell lipids In contrast, when complex lipids labelled with carbon-14 were presented to the cells, the label appeared in the fraction in which it was introduced to the suspension These results suggest that the radioactivity found in association with cell lipids after incubation with labelled triglycerides, phospholipids or chylomicra does not represent true entry into the cell but rather adherence of complex lipids to surface sites

Table 2 Carbon-14 in Fractions of Leucocyte Lipids after Incubation with Various Lipids labelled with Carbon-14 for 1 hr

Medium	Cell lipids Total radioactivity per cent incorporated into Phospholipids	Non-phospholipids	FFA
^{14}C-1-free fatty acid	54	43	3
^{14}C-1-triglycerides	3	96	1
^{14}C-1-phospholipids	>90	<10	0
^{14}C-1-chylomicra	<10	>90	0

FFA, free fatty acid

An alternative possibility would be that the labelled complex lipids were sequestered inside the cells after having been phagocytized but without becoming available to the metabolic machinery of the cell This consideration appears unlikely since it has been clearly shown that phagocytosis constitutes an active metabolic event for which anaerobic glycolysis delivers the energy and also that increased uptake of oxygen usually accompanies phagocytosis by polymorphonuclear leucocytes[7] In these experiments low-temperature incubation and glycolytic inhibition had no effect on the incorporation of radiocarbon from complex lipids, while no increase in uptake of oxygen was observed on addition of chylomicra or oil emulsions to the cell suspensions

These investigations therefore indicate that true metabolic incorporation of lipid by polymorphonuclear leucocytes is evident only in the case of free fatty acid, which become esterified during uptake It was found that this esterification was almost complete as soon as association of ^{14}C-1-free fatty acid with cell lipids had occurred, and furthermore, that homogenization of the leucocytes reduced the degree of esterification by 90 per cent or more even in the presence of added co-factors These findings suggest that esterification of free fatty acid occurs at the cell surface during uptake, the rate of transport may be a function of the availability of L-α-glycerophosphate, perhaps generated by the existence of a complete anaerobic glycolytic pathway in the cell membrane as has been suggested for muscle cells[8]

The remarkable selectivity of the process of uptake of lipid by these cells might rest on interaction between carboxyl groups of fatty acids and reactive groups on the cell surface In the case of complex lipids, these carboxyl groups are not available for interaction and no transport takes place

Possible Magnitude of Inhibition of Coenzyme-Substrate Reactions by Competitive Inhibitors in Coenzyme Preparations

An obvious source of error in enzyme kinetic studies is the presence of competitive inhibitors in impure coenzyme preparations, especially perhaps in the unstable reduced phosphopyridine nucleotides In recent years, the availability of coenzymes more than 90 per cent pure has been reassuring except in the unlikely event that an inactive nucleotide, for example, has a much greater affinity for the enzyme than has the coenzyme, it would seem that a few per cent of such a competitive inhibitor in the coenzyme preparation could not produce a significant effect on the rate of reaction—especially if the coenzyme is very firmly bound to the enzyme, as in the case of reduced diphosphopyridine nucleotide (DPNH) and liver alcohol dehydrogenase (*vide infra*)

Consideration of the possible kinetic effects of a competitive inhibitor, present in fixed molar ratio to the coenzyme, suggests that this reassurance may be ill-founded Consider the effect of an inhibitor, I, which competes with the coenzyme, C, by forming an inactive compound, EI, in an enzyme-catalysed reaction which follows a compulsory order mechanism, for example[1]

$$(1)\ E + C \rightleftharpoons E\,C,\quad (2)\ E\,C + S \rightleftharpoons E\,C' + S',\quad (3)\ E\,C' \rightleftharpoons E + C'.$$

In the absence of inhibitor, the relation between the initial rate in the steady state, v_0, the enzyme concentration, e, and the coenzyme and substrate concentrations, c and s, for such a sequence is of the form[2]

$$\frac{e}{v_0} = \varphi_0 + \frac{\varphi_1}{c} + \frac{\varphi_2}{s} + \frac{\varphi_{12}}{cs} \qquad (1)$$

This is true whether or not rate-limiting ternary complexes are postulated in reaction (2) The kinetic coefficients φ_0, etc , are functions of the rate constants in the mechanism, φ_0 is the reciprocal of the maximum rate, V, obtained with infinitely large coenzyme and substrate concentrations, $\varphi_1/\varphi_0 = K_m$, the Michaelis constant for the coenzyme, defined as the concentration which, with infinitely large concentration of substrate, gives half the maximum rate, and $\varphi_{12}/\varphi_2 = K_1$, the dissociation constant of the enzyme–coenzyme complex $E\,C$ (ref 2)

In the presence of concentration i of a competitive inhibitor, the initial rate equation is[2]

$$\frac{e}{v_0} = \varphi_0 + \frac{\varphi_1}{c}\left(1 + \frac{i}{K_i}\right) + \frac{\varphi_2}{s} + \frac{\varphi_{12}}{cs}\left(1 + \frac{i}{K_i}\right)$$

where K_i is the dissociation constant of EI If the coenzyme preparation itself contains an inhibitor, in molar ratio $i/c = r$ then

$$\begin{aligned}\frac{e}{v_0} &= \varphi_0 + \frac{\varphi_1}{c}\left(1 + \frac{rc}{K_i}\right) + \frac{\varphi_2}{s} + \frac{\varphi_{12}}{cs}\left(1 + \frac{rc}{K_i}\right)\\ &= \varphi_0\left(1 + \frac{\varphi_1 r}{\varphi_0 K_i}\right) + \frac{\varphi_1}{c} + \frac{\varphi_2}{s}\left(1 + \frac{\varphi_{12} r}{\varphi_2 K_i}\right) + \frac{\varphi_{12}}{cs}\\ &= \varphi_0\left(1 + \frac{K_m r}{K_i}\right) + \frac{\varphi_1}{c} + \frac{\varphi_2}{s}\left(1 + \frac{K_1 r}{K_i}\right) + \frac{\varphi_{12}}{cs}\end{aligned}$$

This equation is of the same form as equation (1) Experimental determination of the kinetic coefficients in the usual way, by initial rate measurements with various coenzyme and substrate concentrations and double reciprocal plots[2], will give φ_1 and φ_{12} unaffected by the presence of the inhibitor, but the apparent φ_2 will be $\varphi_2\left(1 + \frac{K_1 r}{K_i}\right)$ and the apparent φ_0 will be $\varphi_0\left(1 + \frac{K_m r}{K_i}\right)$ The maximum rate $1/\varphi_0$ in presence of inhibitor will be $V\Big/\left(1 + \frac{K_m r}{K_i}\right)$, and the apparent Michaelis constant for the coenzyme will be $K_m\Big/\left(1 + \frac{K_m r}{K_i}\right)$

Thus the effect produced on the maximum rate by a constant amount of inhibitor in the coenzyme preparation depends on the relative values of the inhibitor constant and the Michaelis constant for the coenzyme The latter bears no simple relationship to, and may be much larger than, the dissociation constant of the enzyme–coenzyme complex If this is so, a small molar proportion of competitive inhibitor in the coenzyme, which binds to the enzyme no more firmly than the coenzyme, may depress the maximum rate considerably

For liver alcohol dehydrogenase at pH 6 0, the dissociation constant[3] for the DPNH compound is 0 21 μM, and the Michaelis constant[4] for DPNH in aldehyde reduction is 14 μM On the basis of these considerations, kinetic measurements with DPNH containing only 3 per cent of a competitive inhibitor with the same affinity for the enzyme as DPNH would give an apparent maximum rate equal to 0 3 V, an inhibition of 70 per cent

Such effects should be detectable by variations of the maximum rate with samples of DPNH of different purity, and this has been reported for liver alcohol dehydrogenase[5] The magnitude of the differences in rate observed with relatively pure coenzyme preparations was surprising It has since been shown[4] that DPNH freshly prepared in the laboratory from 98 per cent DPN (Sigma) gives a maximum rate of aldehyde reduction at pH 6 0 more than 20 per cent greater than those obtained with commercial samples of high purity (94–97 per cent) Moreover, concentrated solutions (300 mgm /ml) of DPNH in water or 0 4 M disodium hydrogen phosphate, kept in the dark for several hours, give maximum rates less than half that obtained with a freshly prepared solution, yet assay shows that no more than 8 per cent of the active coenzyme has been degraded The above considerations make it easier to understand these observations, and indicate that the purity requirements for coenzymes in kinetic studies may be very exacting, especially when the Michaelis constant for the coenzyme is much greater than the dissociation constant of the enzyme–coenzyme complex Another case in which this appears to be so is the lactic dehydrogenase–DPNH–pyruvate reaction[6], it may be remarked also that, in the presence of a competitive inhibitor, the Michaelis constant for DPNH would be under-estimated to the same extent as the maximum rate

It is readily shown that for a single substrate reaction, formulated in the usual way with one or more binary enzyme-substrate complexes, the kinetic effects of a competitive inhibitor present as an impurity in the substrate will be precisely analogous

Thermal Copolymerization of Protein Hydrolysates containing ^{35}S Amino-Acids and Distribution of Radioactive Sulphur after Application of ^{35}S-labelled Amino-Acid Copolymers in the Rat

THERMAL copolymerization of amino-acids has recently been discussed by Fox *et al* [1–5] The results of these experiments have shown that it is possible to prepare peptides thermally, if aspartic acid or glutamic acid is present in sufficient proportions as a reactant

Thermal copolymerization of amino-acids has yielded anhydropolymers which contain all the eighteen amino-acids common to protein These copolymers have many of the properties of protein[4,6], and after being hydrolysed by hydrochloric acid reveal on paper chromatograms the same amino-acid pattern as protein[2] After chromatography of hydrolysates of proteinoids on ion exchange columns all amino-acids except tryptophan (lost under acid hydrolysis) can be observed on the effluent curve[7,8] Preparations of the same type of proteinoid in different laboratories showed practically the same quantitative amino-acid composition[7,8]

No reports on the administration to mammals of amino-acid copolymers prepared according to Fox *et al* [2,4,5] have been published so far In earlier studies proteinoids (thermal amino-acid copolymers containing all common amino-acids) were seen to be attacked by bacterial proteases[2] and also by proteolytic enzymes of the digestive tract[4-6,8] In further trials the effect of *in vivo* hydrolysis of proteinoids has been tested to obtain information on the breakdown of amino-acid copolymers and on the pathways of the sulphur-containing enzymatic split products of the proteinoids in the mammalian body Experiments have not yet been carried out to test for resulting toxic effects of proteinoids to mammals

Based on these experiences, attempts were made to copolymerize hydrolysates of protein instead of purified amino-acids For this purpose hydrolysates of *Torula utilis* were used This type of yeast was inoculated with sulphate labelled with sulphur-35 to incorporate sulphur-containing amino-acids into the yeast protein[9]

After inoculation *T utilis* was hydrolysed under nitrogen in sealed tubes by 6 N hydrochloric acid for 24 hr to avoid oxidation of sulphur-containing amino-acids The resulting hydrolysates were carefully dried under nitrogen atmosphere and hydrochloric acid was removed by evaporation The residue was dried over phosphorus pentoxide to constant weight

Four parts of aspartic acid, four parts of glutamic acid and one part of dried *T utilis* hydrolysate were dissolved in 5 per cent sulphurous acid

After complete solution of the components, the solvent was evaporated as described for the hydrolysate and the resulting residue was heated under nitrogen for 3 hr at 170° C

The molten mixture was amber in colour After cooling, the vitreous mass was rubbed vigorously with water and after standing overnight the solid was separated by centrifugation Following this the preparation was dissolved in sodium bicarbonate solution and dialysed in cellulose tubing ('Visking' 27/32 in) in an agitated water bath for 4 days Two different types of copolymers could be distinguished One part of the preparation was insoluble (A), while the other part (B) mainly was soluble in water Fraction B is the same as described recently by Fox and Harada[4] Both fractions could be dissolved in sodium phosphate buffer, *p*H 6 8, and precipitations could be achieved as described recently[6] Colour tests which were also positive for protein include biuret, xanthoproteic, Hopkins–Cole, and Salkowski tests as well as the test with azocarmin B These were performed with aliquots of each sample of the polymers All preparations showed a protein-positive reaction and radioactivity

All polymers were pretreated with diluted hydrochloric acid (0 1 N) for 24 hr at room temperature It is assumed that diluted hydrochloric acid removes by-products which may mask peptide bonds when polymerization occurs in the presence of sulphurous acid[8] The diluted hydrochloric acid was removed by dialysis Subsequent to this purification step, samples of the polymers were carefully dried over phosphorus pentoxide and then hydrolysed in sealed tubes under nitrogen The hydrolysates of proteinoids were desiccated to dryness and dissolved in an appropriate volume of sodium citrate buffer, *p*H 2 2 Samples of the hydrolysate containing 2 mgm nitrogen were chromatographed on 'Dowex 50 X 12' columns while the radioactivity was measured by a plastic scintillator spiral flow cell, and the radioactivity was registered on a recorder[10]

The diagram of the sample showed radioactivity at the position of cysteic acid Perhaps some traces of sulphate may appear here also A very small quantity of radioactivity from cystine was measured In spite of the precautions partial oxidation of cystine may have occurred More radioactivity could be observed in the methionine range No radioactive peak appeared at the positions of methionine sulphoxides and methionine sulphone Another radioactive component was eluted from a 150-cm column by 0 2 N sodium hydroxide This active peak was also noticed in hydrolysates of *T utilis* labelled with sulphur-35

These results indicate that it is possible to copolymerize hydrolysates of yeast with dicarboxylic amino-acids and that amino-acids labelled with sulphur-35 can be shown in hydrolysates of the synthesized proteinoid In the feeding trials fraction B of proteinoid was supplied to a male rat (body-weight at the beginning of the experiment was 95 gm) The diet consisted of 86 per cent maize, 10 per cent skimmed milk powder, 3 per cent mineral mixture *USP* XIV and 1 per cent of a complex mixture of vitamins essential for rats

The total mixture of these components could be eaten *ad lib* Twice a day for 7 days, 0 5 ml of a saturated solution of labelled amino-acid copolymer fraction B was administered orally by tube

24 hr after the last proteinoid intake the animal was decapitated After section, no abnormal alteration of the organs could be observed

The tissues in question and the excrements were hydrolysed by 6 N hydrochloric acid in sealed vessels under a nitrogen atmosphere, thus preventing the oxidation of sulphur-containing amino-acids

The hydrolysates were concentrated in a rotary evaporator and dissolved in 0 2 N sodium citrate buffer, *p*H 2 2[11] Aliquots were oxidized according to Denis's method[12], and the radioactivity was measured following the method of v Erichsen and Muller[13] The insoluble residues after hydrolysis were oxidized according to Stotz[14] The results are summarized in Table 1

Table 1 PERCENTAGE OF RADIOACTIVITY RECOVERED

Tissue resp organ	In hydrolysate	In hydrolysate residue	Total
Blood	4 53	0 81	5 34
Skin and hair	0 98	0 19	1 17
Liver	12 04	2 42	14 46
Kidneys	1 08	0 28	1 36
Brain	1 97	0 40	2 37
Digestive tract (tissue)	0 66	0 28	0 94
Rest of body	6 64	2 07	8 71
Excrements			
Digestive tract (content)	1 09	0 84	1 93
Fæces	48 08	10 98	59 06
Urine	3 89	0 67	4 56
Air	—	—	0 10

These results show that proteinoids can be hydrolysed by proteases in the digestive tract *in vivo* and that fragments are absorbed and incorporated in body tissues About 40 per cent of the radioactivity fed was utilized by the rat

The main part of the utilized radioactivity could be found in the liver tissue A relatively high yield of radioactivity was observed in the blood

Some Plant Glycosidases

A NUMBER of sources of plant glycosidases are known, notably almonds and lucerne seed[1] Having suitable substrates available, we have made a survey of a large number of common garden, farm and wayside plants for different glycosidase activities At an early stage attention was concentrated on seeds, since they were at least as rich a source of glycosidases as other parts of plants The species shown in Table 1 are among the highest in enzyme activity other species tended to display the same general patterns of glycosidases There was little difference in any respect between varieties of single species Enzyme preparations were made by grinding the seeds in a glass mortar with a small volume of water to give a smooth paste after dilution this was centrifuged to remove insoluble debris No appreciable enzyme activity was detected with *p*-nitrophenyl α-L-fucoside[2], phenyl β-D-mannoside[3] or phenyl *N*-acetyl-α-D-glucosaminide[4] as substrate in any species examined The absence of β-D-glucuronidase from most plant species has already been noted[5] It is evident that the seeds of common plants form a convenient source of certain glycosidases, and compare favourably in activity with many other known plant or animal sources

Table 1. GLYCOSIDASE ACTIVITIES OF SEEDS

PHYSIOLOGY

Depolarization and Tension in Crustacean Muscle

WHEN nerve impulses bring about the development of tension in a muscle, depolarization of the muscle fibre membranes can be observed The question arises Is this depolarization directly responsible for initiating contraction ? A considerable amount of evidence supports the view that, in frog striated 'twitch' muscle, depolarization of the muscle fibre membrane is a causal link in the excitation–contraction coupling process[1] However, in many crustacean muscles, contraction can occur when depolarizations of very small magnitude are present[2] It is of interest to know whether or not these depolarizations are responsible for bringing about contraction in a direct manner in crustacean muscles Evidence that this is not the case is provided by the experiments reported here, in which the depolarization of the muscle fibre membrane associated with contraction caused by stimulation of the motor nerve was found to be much less than the depolarization associated with tension development produced by adding solutions containing high potassium concentrations to the muscle

The muscle used in these experiments was the abductor muscle of the first walking leg of the crayfish *Astacus fluviatilis* This muscle is relatively small, consisting of a flat sheet of 30–40 muscle fibres, hence it can be quickly depolarized by adding van Harreveld's solution[3] containing excess potassium All the muscle fibres are innervated multiterminally by a single excitor axon, and electrical responses of different muscle fibres to stimulation via this axon were found to be quite uniform Electrical recordings from single muscle fibres were made by means of glass intracellular electrodes of 5–15 M ohms resistance and low tip potential[4] Usually it was possible to examine several cells from a given preparation during the course of an experiment Mechanical responses of the muscle were recorded isometrically at the tip of the dactyl by means of an *RCA* 5734 transducer

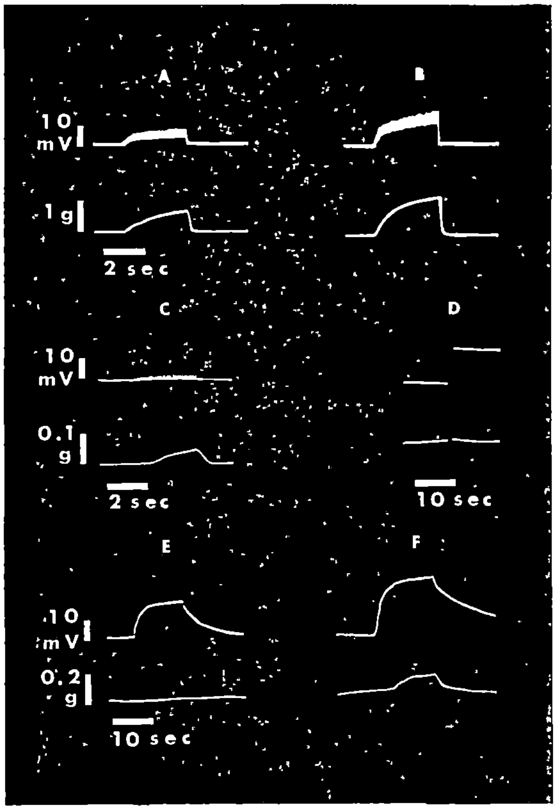

Fig 1 Tension (lower traces) and intracellularly recorded membrane potentials (upper traces) from representative crayfish abductor muscle preparations *A,B*, Responses to a train of stimuli at 70/sec (*A*) and 100/sec (*B*) delivered via the excitor axon, *C*, responses from a different preparation to a train of stimuli at 15/sec , *D*, potassium depolarization in the same muscle fibre, parts of two consecutive traces before and 40 sec after addition of a solution containing 15 m*M* potassium, no tension is developed, *E,F*, responses of another preparation to solutions containing 15 m*M* potassium (*E*) and 22 m*M* potassium (*F*), normal saline is restored after a few seconds in potassium-rich saline

Results obtained from representative preparations during stimulation of the excitor axon at various frequencies are shown in Fig 1 *A,B,C* At low frequencies, small junction potentials of 2–5 mV are produced (Fig 1 *C*), these may grow slightly in size during a train of stimuli As the stimulation frequency is increased, the size of the junction potentials increases and a depolarization 'plateau' is built up (Fig 1 *A,B*) Total depolarization due to junction potentials plus 'plateau' usually amounts to about 15 mV during a three-second period of stimulation at 100 per second However, measurable tension results at quite low frequencies of stimulation (5–15/sec) when the junction potentials are only 2–5 mV , with practically no 'plateau'

When solutions containing excess potassium are added to the muscle, fibres examined in all parts of the muscle show prompt depolarization which can be reversed by returning the muscle to normal 5 m*M* potassium saline Fig 1 *D* shows the electrical response to a solution containing 15 m*M* potassium of the fibre recorded from Fig 1 *C*, the initial resting potential of which was 80 mV A depolarization of 18 mV was produced, but no tension was developed by the muscle In the experiment recorded in Fig 1 *E*, a solution containing 15 m*M* potassium was added to another muscle for a few seconds, after which the normal saline was restored A reversible depolarization of 17 mV was recorded from the fibre examined (which had an initial resting potential of 79 mV) but no contraction occurred The procedure was then repeated using a solution containing 22 m*M* potassium and recording from the same fibre (Fig 1 *F*) A depolarization of 28 mV was recorded, and in this case contraction of the muscle was produced

These experiments, and many others of a similar nature which were performed, indicate that potassium contracture does not occur unless the membrane potential is lowered past a 'threshold' of 55–60 mV. Experiments performed on muscles of *Carcinus maenas* yielded similar results A 'threshold' of this nature does not exist for contractions produced by nervous stimulation, contraction can occur when depolarizations of only a few mV are present It is possible, therefore, that contraction in many crustacean muscles is not brought about by depolarization, but by some other action of the transmitter agent

Apparently there are two separate ways in which the contractile mechanism in crustacean muscles can be activated (*a*) by the nerve impulse and its consequent junctional effects, without necessarily producing much depolarization of the muscle-cell membrane, (*b*) by a sufficiently large depolarization of the muscle fibre membrane In those crustacean muscles which show 'spikes', or in which the electrical responses exceed the depolarization 'threshold', both activating mechanisms may be used, and the contraction-producing transmitter action is probably supplemented by tension developed when depolarization passes the 'threshold'.

Effect of Alloxan on the Insulin Content of Micro-dissected Mammalian Pancreatic Islets

The development of techniques for dissection and weighing of µgm pieces of tissues[1] has provided a method for the isolation of frozen dried sections of mammalian islets The availability of a very sensitive bioassay method for insulin[2] has permitted a direct assay of the insulin content of individual islets We have undertaken the examination of the insulin content of micro-dissected islets from normal and diabetic rats at various times after alloxan injection

Pancreas was obtained from normal rats and from animals given alloxan intravenously (50 mgm /kgm body-wt) The rats were killed by decapitation 2, 24, 48 and 72 hr after alloxan injection The pancreas was frozen in liquid nitrogen (– 196° C) immediately on removal The frozen tissue was sectioned in a cryostat at 20µ at – 20° C , the sections were dried under vacuum at – 40° C [1] The dried sections were stored under vacuum at – 20° C Just prior to the time of assay, they were brought to room temperature under vacuum The islets were dissected from acinar tissue under a binocular dissecting microscope and weighed on a quartz fibre balance[1,4] The individual islets, weighing between 0 05 and 0 20 µgm , were suspended in 1 ml of bicarbonate buffer (*p*H 7 4) containing glucose (100 mgm /100 ml), gelatin (2 mgm /ml), and glucose-1-^{14}C (0 2 µc , *S A* = 12 µc /

Table 1 EFFECT OF ALLOXAN ON THE INSULIN CONTENT OF MICRO-DISSECTED RAT ISLETS

Treatment	Time after injection (hr)	No of animals	Total No of islets assayed	Blood sugar at time of death (mgm /100 ml)	Insulin content μunits/μgm dry wt: Average of all determinations	Range of values for individual rats	*S E* of individual islets assayed
Islet tissue							
Saline injected Normal controls	2	3	23	85–103	3,604	2,617–4,137	±436
Alloxan injected	2	4	13	101–207*	4,027	3,267–5,477	±628
Alloxan injected	24	3	10	315–545	3,635	2,917–4,608	±497
Alloxan injected	48	5	20	305–573	155	0–327	—
Alloxan injected	72	3	13	536–846	93	25–285	—
Acinar tissue from normal controls	—	8	—	—	53	0–179	—

* The 2-hr blood sugar values of rats injected with a diabetogenic dose of alloxan may be normal, hyperglycæmic or hypoglycæmic

mgm) The vessels were equilibrated for 5 min with a mixture of 95 per cent oxygen and 5 per cent carbon dioxide, and incubated in a Dubnoff metabolic shaker at 37° C for 3 hr The conversion of glucose labelled with carbon-14 to carbon dioxide, lipid or glycogen was determined, carbon-14 was measured using a liquid scintillation counter

Micro-dissected islets from normal control rats (saline injected) contain an average of 3,600 μunits of insulin per μgm of dry weight tissue If one assumes that 1 μgm of crystalline insulin is equivalent to 25,000 μunits, then the observed insulin content of the normal rat islet is 14 5 per cent of the dry weight In comparison to the islets, the pancreatic acinar tissue contained negligible amounts of 'insulin-like' activity In a preliminary report by Williamson and Lacy[3] similar values have been found in the micro-dissected rabbit islet tissue composed primarily of β-cells

We have also determined the insulin content of the rat pancreas using an acid alcohol extraction procedure and the epididymal fat pad assay method, values of 1 84 units/gm wet wt were obtained This value agrees closely with that reported in the literature (2 units/gm wet wt [5]) obtained by the mouse convulsion assay method Assuming that the islet tissue comprises 1 per cent of the weight of the pancreas and that the water content of this tissue is 70 per cent, the calculated insulin content of the islet tissue is 700 μunits/μgm dry wt, or 2 75 per cent of the dry weight This value is only one-fifth of that obtained for micro-dissected islets

As shown in Table 1, the insulin content of islets obtained from rats killed 2 hr after injection of alloxan contained the same amount of insulin as the islets from control rats At 24 hr, despite elevated blood sugar levels, the insulin content was unchanged However, at 48 and 72 hr after alloxan administration, the insulin content of the islets was markedly decreased to values less than 5 per cent of that of the controls This observation confirms those of Wrenshall *et al* [6], who found a decrease to 5–10 per cent of the control values in the insulin content of whole rat pancreas within 48 hr after injection of alloxan Our finding that the insulin content of the micro-dissected islets is normal at a time when the blood sugar is elevated (24 hr after alloxan administration) suggests that this drug may affect the mechanism of release (or secretion) of insulin The insulin contained in the damaged β-cells may not be liberated into the blood stream because of an alteration in the permeability of the cell membrane, it has been reported that alloxan selectively alters the permeability of the islet tissue in fish[7] The sharp decrease in the insulin content of the islets at 48 hr after alloxan may be attributed to its destruction 'locally'

This investigation shows that the epididymal fat pad method is sensitive enough to determine the insulin content of micro-dissected islet tissue, and to detect changes in the insulin content following alloxan administration It shows that the insulin in the pancreas is largely confined to the islet tissue The findings reported here emphasize the need for further study of the relationship between 'native' insulin as found in the micro-dissected islet tissue, and the insulin which is extracted from the pancreas by acid alcohol

This investigation was supported by research grants *A*–1659 and *A*–1887 from the National Institute of Arthritis and Metabolic Diseases, National Institutes of Health, U S Public Health Service

Regulation of Sodium Excretion and Retention by the Intestine in Cows

IT is well known that the kidney is the principal organ regulating sodium retention and excretion in order to maintain a constant sodium-level in the blood and tissues (sodium homeostasis)

With regard to sodium absorption in the gut, it also has been shown that the behaviour of the intestinal wall is not merely passive, so that there would be a tendency towards equal concentrations of sodium in the intestinal and fæcal juices on one hand and in the blood plasma on the other In cows, however, Van Weerden[1,2] showed that, in the lower part of the small intestine and in the large intestine, sodium absorption occurs against a considerable concentration gradient so that relatively little sodium is lost with the fæces This indicates that the cow can subsist on surprisingly small quantities of sodium in the feed Van Weerden[1] stressed the importance of this fact because, ordinarily, pasture and other cattle feeds are very poor in sodium

It seemed of interest to examine whether final concentration of the sodium in the fæcal juice is

Table 1 SODIUM, POTASSIUM AND FREEZING POINT DEPRESSION IN FÆCAL JUICE, URINE AND MILK

Period	Days after beginning of exp	Intake per day (m equiv)		Fæcal juice			Urine (m equiv /100 ml)		Milk (m equiv /100 ml)

always the same or whether it is dependent on the amount of sodium in the feed, in other words Does the intestinal wall take part in establishing sodium homeostasis, and if so, to what extent in comparison with the kidney ?

With laboratory animals and human subjects it has already been shown that the specific sodium absorption in the intestine works more efficiently when sodium intake is lower than normal[3–6] So far as we know such observations have not yet been made with cows In this species the problem might be more complicated, because the fæcal juice is always hypotonic as compared with the blood[7]

Two heifers (Exp I) and one milch cow (Exp II) were given sodium-poor rations containing 2 7–5 3 gm sodium per day per animal (low sodium period) In a second period the same rations were fed, but in addition 100 gm of sodium chloride (± 40 gm of sodium) per day per animal was added to the concentrates (moderate sodium period) Finally, the animals received again the low sodium rations (second low sodium period) In Exp I the basal ration consisted of rye straw, hay of mixed grasses, maize meal, linseed meal and calcium carbonate, and in Exp II of rye straw, hay of mixed grasses, potatoes, mixed concentrates and calcium carbonate

Determinations were made of the dry matter in the fæces, and of sodium and potassium in fæces, urine and milk Moreover, press juice (ultra-filtrate) was obtained by pressing the fæces in a membrane press through 'Cellophane' with the aid of nitrogen gas at a pressure of 10 atmospheres[1] In this juice sodium, potassium and osmotic pressure (by freezing point depression) were determined

The average results of the experiments are shown in Table 1 Those of the second low sodium period in Exp II are, however, omitted because in this period the sodium content of the ration was higher than expected

During the low sodium periods, the sodium concentrations in the fæcal juice and in the urine were distinctly lower than during the moderate sodium periods There was also a small but significant decrease of sodium concentration in the milk ($P < 0\ 01$)

In the low sodium periods of both experiments, the potassium concentrations in the fæcal juice were distinctly higher than in the moderate sodium periods In Exp I the same was true for the urine In Exp II, however, there was little difference in this respect

The freezing point depression of the fæcal juice was always within the same range as has been found by Van Weerden[1] thus much smaller than that in the blood In this respect, there was no significant difference between the moderate and the low sodium periods Therefore, the increase of potassium concentration in the low sodium periods can be supposed to be produced by a substitution of sodium by potassium, the former being selectively absorbed from the intestinal contents In dogs such a substitution has already been found by Field *et al* [8] and in human subjects by Spencer *et al* [5]

In Exp II milk, fæces and urine were weighed daily In both periods of this experiment the quantity of fæces amounted to 34–35 kgm a day In the moderate sodium period the average daily excretion of sodium with the fæces amounted to 752 m equiv or 17 3 gm In the low sodium period it was only 196 m equiv or 4 5 gm During the low sodium period the excretion of sodium with the fæces was therefore reduced to about a quarter as compared with the moderate sodium period Thus, 556 m equiv or 12 8 gm sodium was saved from being excreted with the fæces

The figures in Table 1 refer to the whole periods In the latter part of the low sodium period of Exp II the sodium content of the press juice decreased to only 0 20 m equiv /100 ml or even less, that is, about 1/10 of its normal level of about 2 m equiv /100 ml press juice In this case the sodium was absorbed from the intestinal contents against a 75-times higher concentration gradient It is therefore clear that, besides the kidneys, the gut plays an important part in the regulation of sodium metabolism of the cow on sodium-poor diets

Plasma Creatine- and Creatinine-Levels in Sheep

Blanch and Setchell[1] have reported the occurrence of creatinuria in fed, normal sheep They found no increase in creatine excretion occurred during a six-day fast Plasma creatine-levels were found to average 2 62 and 3 01 mgm per 100 ml in four fed and four fasted sheep respectively

During the course of experiments involving starvation of both pregnant and non-pregnant ewes we have also studied plasma creatine- (and creatinine) levels Results substantially different from those of Blanch and Setchell were obtained

The animals used comprised three non-pregnant and twenty pregnant cross-bred ewes Pregnant ewes were about one month from lambing at the beginning of the experiment The animals had been well fed and were in good condition before starvation, which was carried out in semi-exposed pens Drinking water was freely available during the fast Blood was obtained from the jugular vein, heparin being used as anticoagulant Separated plasma was deproteinized with trichloroacetic acid Preformed creatinine and 'total creatinine' (preformed creatinine plus creatine after conversion to creatinine) were determined colorimetrically (Pearce, unpublished method) Creatine was calculated by difference, the results being expressed in terms of creatinine

The results obtained are given in Table 1 It may be seen that in the fed sheep the creatine-levels were similar to the average level of 2 26 mgm /100 ml (expressed as creatinine) found by Blanch and Setchell However, on starvation of pregnant sheep a large increase in plasma creatine was found Non-pregnant sheep responded to starvation with a much smaller initial rise in creatine However, the increase became appreciable by the ninth day of starvation

Some of the pregnant sheep developed, during the course of the fast, certain clinical signs similar to those seen in ovine 'pregnancy toxæmia'[2-5] Of these animals some recovered when re-fed and are included in group *A* in Table 1, together with fasted pregnant sheep in which clinical signs were not observed Other sheep, showing clinical signs, failed to recover although offered food, and died at various times during the refeeding period These deaths, with one exception, occurred prior to parturition Animals of this type are included in group *B* in Table 1 It may be seen that during the fast animals in group *B* showed higher plasma creatine-levels than animals in group *A* On refeeding plasma creatine fell in group *A* to low levels but continued high in group *B* Indeed some animals in the latter group showed the highest levels during the refeeding period The difference between the two groups is still more clearly seen if the average of the last available sample (that is, the last sample before death) for animals in group *B* is considered This was no less than 9 82 mgm creatine (as creatinine) per 100 ml plasma (range 3 6–24 1) Since a gap of several days occurred in some cases between the last sampling and death, even this figure is probably lower than the true terminal average

Results for plasma creatinine are also set out in Table 1 Only slight changes occurred in non-pregnant and group *A* sheep, but a substantial increase occurred during the terminal phase in group *B* The effect is again more clearly seen by considering the last sample obtained before death, which averaged 3 09 mgm creatinine per 100 ml plasma (range 0 76–7 80) It may be remarked that unpublished results for plasma

Table 1 PLASMA CREATINE AND CREATININE IN SHEEP

	Creatine							Creatinine

	0	4	6	9	11	2	10	0	4	6	9	11	2	10
Non-pregnant (3 ewes)	1 99 {1 6–2 4}	2 56 {2 3–3 1}	2 69 {2 4–3 4}	4 50 {3 3–6 8}	3 23 {2 7–3 6}	2 12 {2 0–2 4}	2 36 {2 1–2 6}	0 94 {0 91–0 96}	0 97 {0 82–1 2}	0 98 {0 83–1 1}	0 92 {0 88–0 96}	0 99 {0 96–1 0}	0 96 {0 80–1 2}	1 20 {1 1–1 3}
Pregnant group *A* (9 ewes)	2 01 {1 5–2 6}	3 84 {3 0–8 0}	3 41 {2 8–4 5}	4 18 {3 5–5 6}	4 23 {3 2–6 0}	4 05 {3 1–6 2}	1 63 {0 7–2 3}	1 02 {0 75–1 2}	0 97 {0 82–1 1}	0 96 {0 75–1 1}	1 06 {0 92–1 3}	1 01 {0 80–1 2}	0 99 {0 84–1 2}	0 86 {0 63–1 0}
Pregnant group *B* (11 ewes)	2 20 {1 3–3 0}	3 92 {3 3–5 4}	3 50 {2 4–4 4}	5 40 {4 1–7 5}	6 75 {3 5–24 1}	7 44* {3 6–18 9}	12 70† {5 4–16 9}	0 95 {0 80–1 2}	0 97 {0 77–1 2}	0 99 {0 75–1 3}	1 12 {0 80–1 84}	1 35 {0 88–2 6}	1 83* {0 76–6 1}	5 63† {1 6–7 8}

Results are expressed in terms of creatinine, mgm /100 ml plasma, followed by the range of results in brackets * 8 sheep only † 3 sheep only urea also indicate marked nitrogen retention in animals dying from experimentally induced 'pregnancy toxæmia'

The reason for the discrepancy between our results for creatine and those of Blanch and Setchell is not clear It seems possible that the ewes used by the latter workers may have been non-pregnant—in our study animals of this type showed comparatively little change in plasma creatine after six days starvation (the period used by Blanch and Setchell) in contrast to the larger changes seen in pregnant animals Of possible significance also is the observation that in the pregnant sheep plasma creatine-levels tended to be lower on the sixth day than on the fourth, ninth or eleventh days of the fast A possible difference in specificity of the method used for creatine in our work would also account for the discrepancy but is believed to be rather unlikely

We thank Messrs Imperial Chemical Industries, Ltd , for a grant in support of these experiments

Sea Salt and Dental Caries

Experience in the United States and elsewhere has shown that the main source for the fluoride intake in man for the partial prevention of dental caries is the water supply Results from recent investigations in India and Greece strongly suggest that the daily consumption of sea salt by the people of these countries may have been another major source of dietary fluoride Sea salt was reported to contain 40 p p m of fluoride[1] The fluoride content of teeth from India and Greece was found to be considerably high although the level in the water supplies was negligible[1,2] In addition, the prevalence of caries in the two countries has been reported to be low[1,3]

It is generally believed that children up to 12 years of age consuming water containing continuously about 1 0 p p m of fluoride will ingest from water alone approximately 0 4–1 0 mgm of fluoride daily, amounts which will provide considerable protection against caries In order to ingest these levels of fluoride entirely from sea salt, containing 40 p p m of fluoride, a daily intake of about 10–25 gm would be required However, significant reduction in caries has been also observed in children using water alternating in its natural fluoride content from day to day between 0 2 and 1 0 p p m [4] It thus seems likely that intermittent ingestion of sea salt in amounts comparable with the above-mentioned may also result in a fluoride intake sufficient to provide considerable protection against caries

The ingestion of high amounts of salt is not unlikely among people of certain countries because of their dietary habits and food customs It has been reported that the ration of the armed forces of the Republic of Korea included 30 gm of crude sea salt per man per day[5] Furthermore, up to twice this amount was ingested daily from the consumption of native food preparations containing high amounts of sea salt[5] In this connexion, it may be significant that susceptibility to caries among the men of the armed forces was found to be very low[5] In a nutritional survey of the armed forces of Iran it was shown that an allowance of about 30 gm of salt per man per day, obtained from mines, was included in the menu[6] The amount of sea salt produced by salterns in Greece annually indicates that the daily ingestion by the population may be considerable[7] In addition, experiments with laboratory animals indicated that increasing the calcium-level in the diet decreased the amount of fluoride absorbed from the intestinal tract[8] Therefore, in countries where the level of calcium intake is low there may be an increase in the absorption of the ingested fluoride, thus a smaller amount of dietary fluoride would be required daily for protection against caries

In conclusion, it is proposed that serious consideration should be given to the role of sea salt as an important source of dietary fluoride for the prevention of dental caries in areas of the world where the salt consumed locally is prepared by evaporating sea water

Spontaneous Hydronephrosis in Albino Rats

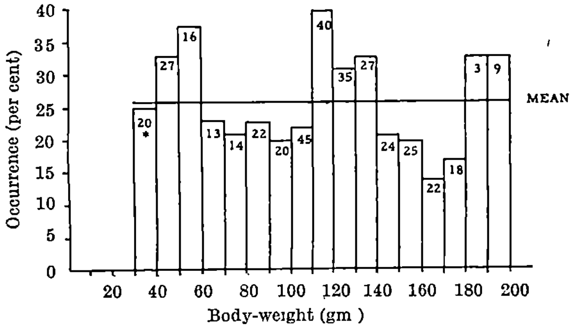
During the course of an investigation on the influence of the pituitary gland on compensatory renal hypertrophy in rats[1], a surprisingly high incidence of hydronephrosis was encountered This made it necessary to discard a great number of animals The failure to find any reference to spontaneous hydronephrosis in rats in the literature has prompted this preliminary report[2–6]

Table 1. Summary of Data on Incidence of Hydronephrosis in Albino Rats

Sex	No of rats	No of rats with hydronephrosis	Percentage of hydronephrosis
Male	415	104	26 3
Female	371	6	1 6

Autopsy findings on 786 rats are presented in Table 1 The rats, which were apparently healthy, were killed because they served as controls in certain experiment or they had to be replaced by younger rats for the maintenance of the colony in the Unit Only kidneys showing gross dilatation of the pelves and calices were considered to be hydronephrotic A careful search for calculi in the urinary passages (pelvis, ureter and bladder) was carried out but none was found Hydronephrosis was almost entirely confined to the right kidney and was much commoner in the male The age of the rats (judged by the body-weight) did not seem to affect the incidence of hydronephrosis

The following findings in two rats is of exceptional interest In one the right kidney was completely absent and the left kidney had increased in size to a considerable extent (left kidney wt mgm /body wt gm 2632/385) The weight of the two kidneys in a rat of the same weight would be 3,000 mgm (ref 7) In the second rat the right kidney was completely replaced by a kidney-shaped transparent cyst filling up the entire lumbar space and containing clear yellow fluid which looked like urine The ureter was greatly dilated and was in its usual anatomical position Both were male rats



* No of rats per group

Fig 1 Hydronephrosis in male albino rats

To our knowledge, this is the first report of spontaneous hydronephrosis in the rat, not associated with calculi or infection The failure to find calculi in the urinary passages, however, does not rule out the possibility of their presence as microscopic crystals in the renal tubules with consequent blocking and atrophy of the renal parenchyma and dilatation of the calices and pelves Although the origin of the rats in this colony is not known exactly, they are believed to be of the Wistar strain They have been maintained as a closed colony for 14 years The fact that no hydronephrosis or renal calculi was found in any of the 400 rats which were autopsied at the Wistar Institute is interesting

One can only speculate about the cause of the spontaneous hydronephrosis which has been observed in these rats The possible presence of intrarenal calculi has already been mentioned Another possibility is that the peristaltic mechanism of the ureter might be unco-ordinated or at fault A genetic stigma which is transmitted in the male rat as a dominant character would appear probable It is hoped that this report will stimulate investigators in the field of renal science to shed new light on the pathogenesis of hydronephrosis

HÆMATOLOGY

Two Types of γ_{1A}-Globulin in Sera from Normals and Patients with Multiple Myeloma

The $\gamma_{1A}(\beta_{2A})$-globulins of normal human serum and the γ_{1A}-myeloma proteins are structurally related to the other immune globulins and Bence Jones proteins[1,2] This communication presents evidence for the existence of two antigenically distinguishable types of γ_{1A}-myeloma proteins Each of these is closely related to one of the major immunologically defined types of Bence Jones proteins[3] and each of them appears to have an antigenically distinct counterpart in the normal γ_{1A}-globulin fraction

An electrophoretically homogeneous preparation of pooled normal γ_{1A}-globulin[4] gave 2 distinct precipitin lines by double diffusion with an antiserum to 7*S*-γ-globulin, while electrophoretically isolated γ_{1A}-myeloma proteins generally gave only one line and could be divided into two antigenically distinguishable groups (Fig 1*A*) Six proteins afterwards classified as belonging to group *A* on the basis of their relationship to group *A* Bence Jones proteins gave a reaction of complete or partial identity with the inner line of normal γ_{1A}-globulin while the other 6, classified as group *B*, fused with the outer line but penetrated through the inner one (Fig 1*A* and *B*) Proteins within each group gave a reaction of complete or partial identity with each other and a reaction of non-identity with those of the other group (Fig 1*A* and *B*) An antiserum specific for γ_{1A}-globulin showed certain common determinant groups on all proteins since all gave a reaction of partial identity (Fig 1*C*) When compared to 9 Bence Jones proteins of groups *A* and *B*, one group gave a reaction of complete or partial identity with Bence Jones proteins of group *A* and was therefore called group *A*, while the others were antigenically related to Bence Jones proteins of type *B* and referred to as group *B*[3] (Fig 1*D* and 1*E*) Antisera prepared against each of the γ_{1A}-myeloma groups reacted only with myeloma and Bence Jones proteins of the same type

The 2 classes of γ_{1A}-globulin did not differ from each other in electrophoretic mobility, sedimentation properties and hexose content All but one of the proteins had a major component with a sedimentation-rate of 7*S*, and 10 had additional peaks with sedimentation-rates of approximately 10, 13 and 15*S* These were unaffected by *p*H 3–4 or 30 per cent urea but were reduced to 7*S* units by 0 1 *M* mercaptoethanol Hexose of normal γ_{1A}-globulin was 5 5 per cent and that of proteins in both groups ranged from 4 to 6 per cent with the exception of one of the group *A* proteins which contained only 1 1 per cent Similarly the 3 5–3 8*S* units produced from the 2 types by papain[5] were similar They migrated as a single component with a mobility similar to the native protein on immunoelectrophoresis Chromatography on CM cellulose yielded only a single peak with the starting phosphate buffer *p*H 7 6, μ0 01 On DEAE cellulose, papain fragments from normal γ_{1A}-globulin and one of the group *B* myeloma proteins could be resolved into two distinct peaks, while those obtained from one other group *B* and two group *A* proteins came off as single peaks with a high ionic strength buffer[6] The papain fragments lost most of the antigenic determinants specific for γ_{1A}-globulin, but they retained sufficient specificity to permit their identifica-

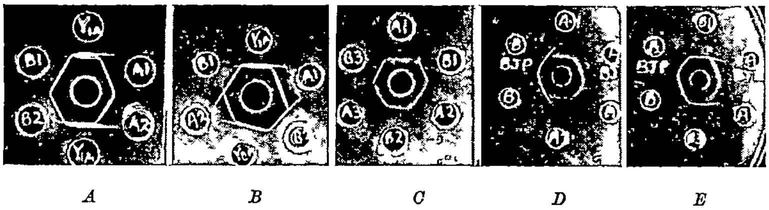

Fig 1 Ouchterlony analyses of *A* and *B*, normal γ_{1A}-globulin (γ_{1A}) and two myeloma proteins of group *A* and group *B* using antiserum to 7*S* γ-globulin in centre well, *C*, three myeloma proteins of each group using antiserum to γ_{1A}-globulin, *D*, two group *A* myeloma proteins (top and bottom) and Bence Jones proteins group *B* (left) and group *A* (right) Antiserum to 7*S* γ-globulin in centre, *E*, two group *B* myeloma proteins (top and bottom) and Bence Jones proteins group *B* (left) and group *A* (right) Antiserum to 7*S* γ-globulin in centre

tion with the same antigenic class as the parent protein

The antigenic similarities noted between the 2 classes of γ_{1A}-globulins and Bence Jones proteins as well as with certain parts of 7*S* and 19*S* γ-globulins suggest that all may contain certain common polypeptide chains of a similar type[7] The genetic control of these is now being investigated[8]

We thank Dr Leonard Korngold for initially classifying two Bence Jones proteins for us This work was supported by the Arthritis and Rheumatism Foundation and U S Public Health Service grants *A*-2594, *A*-1431 and 5141

Hæmoglobin Bart's in Italy

CONTINUING our investigations, already reported[1], we have found 9 cases of hæmoglobin Bart's out of 3,556 samples of cord blood In 7 of these, re-examined after several months, the abnormal hæmoglobin had disappeared In 4 babies, aged from 5 to 10 months, an evident microcythæmic (or thalassæmic) hæmatological picture appeared, in three others, still very young, the hæmatological characters were still uncertain with regard to microcythæmia (or thalassæmia) Examination of the parents, carried out in 8 families, has revealed, in all, the absence of abnormal hæmoglobins, however, in 7 families, one of the two parents showed the hæmatological characters, either pronounced or slight, of microcythæmia, only in one family were the hæmatological characters normal, with the exception of very slight erythrocytic morphological alterations in the mother In our previous communication, we had observed this family only and another one, in which the mother showed rather slight deviations and therefore we thought that we could exclude the existence of any relationship between hæmoglobin Bart's and microcythæmia, however, it must now be that such a relationship exists

The most characteristic observation is that the parents, carriers of microcythæmia, and the sons with hæmoglobin Bart's, re-examined after several months, have never revealed a high portion of hæmoglobin A_2 This fact, which has also been reported by others[2,3], recalls the similar one of families of carriers of hæmoglobin H in which all microcythæmic members and the same carriers of hæmoglobin H always have a normal fraction of hæmoglobin A_2.

The hypothesis may be made that hæmoglobin Bart's and hæmoglobin H appear in the same families in which microcythæmia is present without increase of hæmoglobin A_2, and that is, according to the hypothesis of Ingram and Stretton[3], α-chain microcythæmia

PATHOLOGY

Deoxyribonucleic Acid Measurements on Buccal Cell Nuclei in Megaloblastic Anæmias

MEGALOBLASTIC anæmias, as their name indicates, are characterized by enlargement of the red cell precursors This enlargement affects both nucleus and cytoplasm Some other types of cell are enlarged as well, particularly the immature myeloid cells ('giant band cells') and the squamous epithelial cells of the buccal mucosa Other epithelial cells are sometimes affected, but the changes are inconstant[1]

Interpretations of these findings in terms of the molecular structure of the nuclei are still a matter of speculation Barnard and Lewson[2] have proposed that vitamin B_{12} deficiency results in increased polymerization of DNA, and that this causes nuclear enlargement and hypochromasia Nothing is actually known about the biochemical difference between an affected cell and a normal one Examination of the 'biochemical lesion' in deficiency of vitamin B_{12} and of folic acid has shown that these substances play a part in numerous metabolic processes, not only concerned with nucleic acid metabolism[3,4] The idea that the nuclear changes are due to defective DNA synthesis is not supported by auto-radiographic data[5]

It is not even known whether premitotic megaloblast nuclei contain the same amount of DNA as the corresponding normoblasts Measurements of DNA in interphase nuclei obtained from bone marrow are affected by the proportion of cells which are synthesizing In order to get comparable figures it would be necessary to perform estimations on cells actually in mitosis, and it would not be possible to identify the dividing cells

These difficulties do not apply to the nuclei of buccal epithelial cells Buccal cells are very easy to prepare without the admixture of other cell types, and

* Expected normal value = 110

if they are obtained from saliva they are all fully differentiated and incapable of further division As this seemed a favourable material, we have made microspectrophotometric measurements on buccal cell nuclei of four patients with Addisonian anæmia before and after vitamin B_{12} treatment, and of one patient with puerperal megaloblastic anæmia before and after treatment with folic acid

The saliva was centrifuged to deposit the cells The supernatant was decanted and the cellular deposit was spread between two cover-glasses and air dried A few smears were also made on microscope slides, immediately wet-fixed in ethyl alcohol containing 3 per cent of acetic acid, and stained by Papanicolaou's method

The wet-fixed smears were used for micrometer measurements of nuclear diameters These were performed as described by Boddington[6]

The air-dried smears on cover-glasses were used for Feulgen staining In order to provide a standard whereby different smears could be compared with each other and also with control smears of buccal cells obtained from normal individuals, small pieces of fresh human tissue (thyroid or endometrium) obtained at operation were tapped out in physiological saline, and one or two drops of the resulting cell suspension were gently smeared over the cover-glasses, which were immediately fixed by methanol freezing substitution Controls were fixed and stained at the same time as the smears from patients After staining by the Feulgen procedure, measurements were made with the Deeley integrating microdensitometer[7] incorporating the cell-crushing device[8] A random sample of 30–38 buccal epithelial cells and 15–20 'standard' cells were measured on each specimen The mean stain content, in arbitrary units, of those buccal cells which fell within 20 per cent of the main (diploid) mode was calculated, as was the mean of the standard cells Polyploid cells were recorded separately Assigning a value of 100 to the standard cells, the value for the buccal cells was adjusted accordingly, to give the 'basic DNA value' (usually the standard cells were leucocytes or fibroblasts, when epithelial cells were measured, the value of 110 was taken, since in previous measurements on normal human tissues epithelial cells were found to have approximately 10 per cent greater DNA content than leucocytes and fibroblasts)[9]

The results presented in Table 1 show that buccal cells with typical enlarged nuclei due to vitamin B_{12} or folic acid deficiency have a DNA content which is not measurably different from normal, except that tetraploids, and binucleate cells containing two diploid nuclei, are unusually frequent Only 5 of the 330 cells measured had DNA contents which fell outside the diploid (± 20 per cent) or tetraploid (± 20 per cent) regions After treatment, most of the readings show an insignificant rise (perhaps coincidental) and the tetraploids and binucleates disappear

The general nuclear enlargement observed in these cases therefore remains unexplained, but it is now possible to discard the hypothesis that such nuclei are deficient in DNA The apparently light nuclear staining is presumably due to a normal DNA content being distributed over a larger area in the spread-out nucleus

Induction of Experimental Allergic Encephalomyelitis by Tattooing

TATTOOING has been used in medical practice to introduce certain materials for local effects These have included pigments to modify the appearance of scars, birthmarks or other abnormalities on skin or cornea, titanium oxide to conceal unwanted tattoos, mercuric sulphide to relieve pruritus ani, and steroids to treat local skin lesions The present demonstration that nervous tissue emulsions can be tattooed into the skin of rats in amounts sufficient to cause experimental allergic encephalomyelitis may serve to direct attention to tattooing as an additional method of parenteral inoculation for systemic effect

Experimental allergic encephalomyelitis is induced ordinarily by injection of nervous tissue emulsified in Freund's adjuvant In the present experiments, a 40 per cent aqueous homogenate of spinal cord was emulsified in an equal volume of adjuvant ('Bayol *F*-Arlacel *A*', 85 15) Adjuvants with zero, 4 0 mgm /ml, and 40 mgm /ml killed tubercle bacilli are termed incomplete, complete, and fortified, respectively Female rats of a strain highly susceptible to experimental allergic encephalomyelitis[1] were anæsthetized with ether The emulsion was smeared over the plantar surface of the foot and the electrically operated tattoo needles were passed systematically over this area Some bleeding occurred and the foot was slightly swollen and discoloured for a few days

Among 70 rats tattooed once, experimental allergic encephalomyelitis was detected histologically in 32, two of which had exhibited hind-limb weakness after 13 and 17 days The lesions consisted of mononuclear infiltration of meninges, vessels and perivascular parenchyma with demyelination The incidence varied according to the experimental procedure (Table 1) Tattooing the right hind foot or all 4 feet with an emulsion of rat spinal cord and complete adjuvant produced mild lesions in half the rats Tattooing flank skin, or even ten skin sites on flanks, neck, thighs and base of tail, was almost completely ineffective, thus confirming the superiority of the plantar surfaces of the feet as sites of inoculation[2] Fortification of the adjuvant increased the severity but not the incidence of experimental allergic encephalomyelitis Guinea pig spinal cord antigen was more effective than rat cord It produced moderate or severe lesions in most animals With this antigen, even an emulsion made with incomplete adjuvant was successful, confirming results obtained after injection of corresponding materials[1,3]

Table 1 EXPERIMENTAL ALLERGIC ENCEPHALOMYELITIS (EAE) IN RATS PRODUCED BY TATTOOING ENCEPHALITOGENIC EMULSIONS

Site of tattoo	Spinal cord antigen	Adjuvant	EAE (histological) Incidence*	EAE (histological) Severity†
1 foot	rat	complete	5/10	0 9
1 flank site	rat	complete	0/10	0 0
10 skin sites	rat	complete	2/10	0 1
4 feet	rat	complete	5/10	0 4
4 feet	rat	fortified	4/10	1 1
4 feet	guinea pig	complete	8/10	1 8
4 feet	guinea pig	incomplete	8/10	0 9

* Numerator, number of rats with lesions, denominator, total number of rats

† Average severity of lesions, graded individually from 0 to 4

At time of death, 3 weeks after a single tattoo, the feet were macroscopically normal, but histological examination revealed a few inflammatory cells and granulomas Popliteal lymph nodes were enlarged 2–4 times normal and contained a few macrophages and epithelioid cell granulomas around oil drops The presence of oil drops (derived from the encephalitogenic emulsion) proved that tattooed inoculum is transported to lymph nodes, a fact already known in Virchow's time However, oil drops and inflammatory reaction in feet and lymph nodes following tattoo were inconspicuous compared with the changes following injection of 0 05 ml encephalitogenic emulsion This suggests that minute volumes of emulsion entered the tissues during tattooing Nevertheless, a high incidence of histological experimental allergic encephalomyelitis resulted It is probable that the fine state of dispersion of the inoculum facilitated efficient utilization of antigenic material In fact, the absence of a 'pool' of inoculum (always present after injections of oily materials) may prove advantageous in studies of experimental allergic encephalomyelitis when it is desired to eliminate the possibility of mobilization of antigen from the 'pool' at unpredictable times during the experiment

It has been stated that the function of oily adjuvant in development of hypersensitivity to aqueous nervous tissue antigen requires a stable water-in-oil emulsion[4] Therefore, our results may be taken as evidence that emulsion stability was not destroyed by the process of tattooing

This investigation was supported by grant No 184–4 from the National Multiple Sclerosis Society

Use of Fungizone and Polymyxin *B* in Isolation of Naturally Infected Tissues

TISSUES from lung, urogenital, and intestinal tract which cannot be obtained sterile represent a problem to the isolation and establishment of cell lines

In many instances it was not possible to isolate cell lines due to the overwhelming contamination which naturally occurs in these organs In order to overcome this difficulty, the regular procedures of cell isolation were adapted to the special needs

The tissues from lung cervix and other contaminated material were washed three times in Eagle's medium and 20 per cent pooled human serum The following antibiotics were added

Streptomycin sulphate	100 μgm /ml	(Lilly)
Penicillin *G*	100 U /ml	(Squibb)
Neomycin sulphate	160 U /ml	(Upjohn)
Polymyxin *B* sulphate	50 U /ml	(Burroughs-Welcome)
Fungizone-amphotericin *B*	0 02 mgm /ml	(Squibb)

The tissue was then put into new medium with the antibiotics in the same concentration as indicated above and stored overnight at 4° C The tissue was removed from the solution, minced, and trypsinized in a Bellco spinner flask (Bellco Glass Co , Vineland, New Jersey) on a magnetic mixer at room temperature for 30–60 min The trypsinized suspension was centrifuged for 5 min at 1,500 r p m The trypsin was decanted The cells were suspended in Eagle's medium with 20 per cent pooled human serum, streptomycin[1], penicillin[2], neomycin[3], polymyxin *B*[4], and fungizone[5], and then distributed in 10 ml aliquots into 8-oz milk dilution bottles at the desired concentration Polymyxin *B* and fungizone were continually added to the medium for at least one month It was noted that omission of polymyxin *B* and fungizone from the medium at an earlier date was followed by contamination of the primary sterile culture after the first transfer

It was possible to isolate a cell line derived from a normal cervix, a carcinoma *in situ*, an invasive carcinoma of the cervix, and several carcinomas from the intestinal tract The isolation of a cell line from a gastric lesion was not achieved If a carcinoma of the stomach was washed three times and trypsinized immediately, the culture was heavily contaminated However, if stored overnight at 4° C , no growth occurred Also the growth of preputial tissue has been improved by this method (Dr R G Brackett, Parke, Davis and Co)

In case of contamination of an established cell line with moulds or pseudomonas, the following procedures were instituted The medium was removed The cells were washed twice daily with 10 c c BSS containing double strength of the appropriate antibiotic (fungizone or polymyxin *B*) by rotating the bottle gently The solution was then decanted and new medium added containing 0 04 μgm /ml fungizone and polymyxin *B* 100 U /ml , depending on the type of micro-organism present The infection usually cleared up within 2–3 days by this method Neither the polymyxin *B* nor the fungizone in the concentrations used showed any toxic effect on the cells Since we have adopted this method, we have lost very few cell lines

IMMUNOLOGY

Simultaneous Intradermal Tuberculin Tests

Rosenthal and Libby[1] have shown that the tuberculin reaction to a 10 T U test is reduced by a simultaneous 100 T U test They suggest that there is competition for the available antibody Stone and Bruce[2] and Bruce[3] assumed, implicitly, that simultaneous tests are independent and, explicitly, that there is a constant antibody level λ throughout an intradermal reaction Both assumptions were inessential and the following extension provides a quantitative treatment of simultaneous test data

The equation[2]

$$D^2 = \bar{\alpha} V \log(4\, d \log_e 10/\pi\bar{\alpha}\tau V) \qquad (1)$$

[where $\bar{\alpha}$ = the clinician's constant, D = induration diameter (mm), V = injection volume, d = tuberculin dose (T U) and τ = minimum areal concentration of tuberculin for induration (T U /mm ^{2})] is unaffected by competition between test sites, if it can be assumed that λ, though decreasing with time, is, at any given time, the same at all sites Since a circulating antibody hypothesis is presumably necessary for competition, this assumption is reasonable

Let $\lambda(T)$ be the antibody-level at time T after injection Suppose any tuberculin that escapes into the bloodstream without local reaction quickly reacts there with antibody Also suppose that, if $d(T)$ is the total unreacted dose in all sites at time T

$$\lambda(T) = \lambda_0 - \theta[d_0 - d(T)] \qquad (2)$$

for T 'such that $\lambda(0) = \lambda_0 > \theta[d(0) - d(T)]$ Due to escape and local reaction

$$d'(T) = -\varepsilon d(T) - \omega\lambda(T)d(T) \qquad (3)$$

With $a = \varepsilon + \omega\lambda_0 - \omega\theta d_0$, (2) and (3) give

$$\lambda(T) = \lambda_0 - \theta d_0 + \frac{a\theta d_0 e^{-aT}}{a + \omega\theta d_0(1 - e^{-aT})} \qquad (4)$$

for T such that (4) is positive Let $t(T)$, $r(T)$ be the areal densities of unreacted tuberculin and of reaction products at a particular point of a site Then

$$t'(T) = -\varepsilon t(T) - \omega\lambda(T)t(T) \qquad (5)$$

$$r'(T) = \lambda(T)t(T) \qquad (6)$$

(4), (5), (6) give $r(\infty)$ for the cases $\lambda_0 \lessgtr \theta d_0$, and, if induration just occurs when $r(\infty) = \rho$

$$\rho\omega\tau^{-1} = 1 - \frac{\varepsilon}{\omega\theta d_0}\log_e\left(\frac{\varepsilon + \omega\lambda_0}{\varepsilon + \omega\lambda_0 - \omega\theta d_0}\right) \qquad (7)$$

if $\lambda_0 > \theta d_0$, and

$$\rho\omega\tau^{-1} = \frac{\lambda_0}{\theta d_0} - \frac{\varepsilon}{\omega\theta d_0}\log_e\left(\frac{\varepsilon + \omega\lambda_0}{\varepsilon}\right) \qquad (8)$$

f $\lambda_0 < \theta d_0$

When $\omega\lambda_0/\varepsilon$ is small, that is, if most of the tuberculin escapes local reaction, (7) and (8) simplify to

$$\varepsilon\rho\tau^{-1} = \lambda_0 - \tfrac{1}{2}\theta d_0 \qquad (9)$$

if $\lambda_0 > \theta d_0$, and

$$\varepsilon\rho\tau^{-1} = \tfrac{1}{2}\lambda_0^2/\,\theta d_0 \qquad (10)$$

if $\lambda_0 < \theta d_0$

With τ determined by (1), equations (9) and (10) are testable even though λ_0 (and possibly $\varepsilon\rho$ and θ) will vary from subject to subject Evidence that $\omega\lambda_0/\varepsilon$ is usually small is provided by data previously reported[2] 39 subjects, vaccinated with a range of *BCG* doses, and tested with 100 T U , gave the results (1) the τ's of subjects who received the same *BCG* dose were close, (2) the whole range of τ's was $10^{-0\cdot5}$–10^{-8}; (3) with higher *BCG* doses, τ's down to 10^{-10} would probably have been attainable With the assumption that the value of λ_0 corresponding to $\tau = 10^{-8}$, say $\lambda_0{}^*$, obeyed $\lambda_0{}^* > \theta d_0$, it can be verified that these results imply $\omega\lambda_0{}^*/\varepsilon < 1/50$ and, *a fortiori*, $\omega\lambda_0/\varepsilon \ll 1/50$ for the lower antibody-levels

An immediate prediction of this model is that, for example, the reduction in size of a 10 T U reaction in association with a 100 T U test should be the same as the reduction of a 10 T U reaction in association with two 50 T U tests For the two cases have the same total dose

Fate of Attenuated Tubercle Bacilli (*BCG*) in Germ-free and Conventional Mice

In the course of a study of hyper-reactivity to endotoxin of mice infected with *BCG*, the use of germ-free mice was indicated[1] Since little information is available concerning the response of germ-free animals to infectious agents, especially *Mycobacteria*, the fate of *BCG* in these animals was followed carefully and was compared with that in conventional animals of the same strain

Germ-free mice were obtained from the Lobund Institute, Notre Dame University, Notre Dame, Indiana, and were shipped in a specially constructed germ-free isolator They were transferred to an isolator in the laboratory and kept in the germ-free state (except for those infected with *BCG*) until termination of the experiment. Conventional animals were of the same strain and age. Quantitative estimation of the microbial population in the spleen was obtained by determining the number of viable units of *Mycobacteria* which could be recovered from the triturated organs on Loewenstein–Jensen medium. The tissue reaction to the infection was assayed from histological sections of major organs, especially lymph nodes, lungs, liver and spleen. All determinations were done 12 days after intravenous injection of approximately 5 × 10^6 viable units of *BCG*.

The numbers of recovered organisms from individual spleens are recorded in Table 1. Although there may be some indication, though statistically insignificant, of a difference between the means of the two groups, individual animals cannot be placed in either the germ-free or control group on the basis of the mycobacterial load found in the spleens after intravenous infection with *BCG*.

Table 1. RECOVERY OF *BCG* FROM SPLEENS OF CONVENTIONAL AND GERM-FREE MICE

Mouse No.	No. of viable units × 1,000 per 200 mgm. tissue Germ-free	 Conventional
1	0	0·7
2	1·4	1·8
3	4·2	3·0
4	5·3	3·7
5	5·4	3·7
6	5·6	3·9

8	6·7	5·1
9	6·7	5·1
10	7·2	5·5
11	8·0	5·6
12	8·8	5·6
13	9·7	8·0
14	9·9	8·0
15	12·0	8·3
16	12·0	
17	14·0	
$\bar{x} \pm S.E.$	7·3 ± 3·7 *P* 0·02	4·8 ± 2·2

The cellular response to infection with *BCG* was similar in germ-free and in normal animals. Enlargement of the spleen was accompanied by accumulation of large mononuclear cells with frequent giant cells in spleen and lymph node tissues. Similarly, the number of Kupffer cells in the liver was increased, and many foci of mononuclear cells were present. There was no evidence of necrosis in animals of either group.

The few studies concerned with resistance of germ-free animals to bacterial infection have, in general, shown that these animals are more susceptible than those with a normal intestinal flora. This was the case with infection with *Shigella flexneri* in the guinea pig[2] and with *B. anthracis* in the rat[3]. In the former, the altered resistance is explainable by the absence of bacterial antagonism in the intestinal lumen rather than by decreased reactivity of the tissues. Germ-free animals can be protected against this infection simply by a preceding oral feeding with *Escherichia coli* but not with *Lactobacillus*[4]. A deficiency of the tissue response is assumed to be responsible for the increased pathogenicity of anthrax spores for germ-free rats since the spores are deposited in the tissues. This may be due to the fact that germ-free rats do not contain antibacterial agglutinins or only in very low titre, as against *Staph. epidermidis*[5]. On the contrary, germ-free mice have a relatively high titre of bactericidal antibody against *Escherichia coli*[6]. In addition, the uptake of bacteria by the reticulo-endothelial system of germ-free mice is deficient. This is attributed to the absence of specific opsonins[7].

The results presented indicate that the reticulo-endothelial system of germ-free mice is competent to deal with infection with *Mycobacteria*, possibly because no specific opsonin is necessary for phagocytosis. Furthermore, the capacity to respond with hyperplasia to the presence of tubercle bacilli appears equally well developed in germ-free as in normal mice. The experiments suggest that the germ-free animal represents an excellent tool for the study of natural resistance.

BIOLOGY

Water-soluble Polysaccharides of *Porphyra* Species : a Note on the Classification of *P. naiadum*

THE water-soluble mucilages which are present in copious amounts in the red seaweeds (Rhodophyta) are usually sulphated polysaccharides containing galactose, 3,6-anhydrogalactose and, more rarely, 6-*O*-methylgalactose units. These polysaccharides are by no means identical in all red seaweeds, and it has been suggested[1] that the composition of the mucilage might provide a useful additional criterion in classification within the group. We have now isolated and analysed the water-soluble polysaccharides from some fifty different collections of the genus *Porphyra*, and this communication reports the bearing of our results on the classification of the alga hitherto known as *P. naiadum* And.

It is already known[2,3] that the water-soluble polysaccharides of certain *Porphyra* species contain residues of D-galactose, L-galactose, 3,6-anhydro-L-galactose, 6-*O*-methyl-D-galactose and ester sulphate, and that the relative proportions of some of these components vary from sample to sample. It is further known[4,5] that the sulphate ester of the purified polysaccharide (porphyran) from *P. umbilicalis* f. *laciniata* harvested in June is largely present as 1,2- or 1,4-linked L-galactose 6-sulphate. This ester is hereafter called 'precursor sulphate' since it can be transformed into 3,6-anhydrogalactose through the mediation of an enzyme present in the alga[6].

For these investigations a number of *Porphyra* species was collected from sites on the west coast of Scotland and the Pacific coast of North America. The British species[7] included *P. umbilicalis* (L.) Kutz. f. *umbilicalis* and f. *laciniata* (Lightf.) J. G. Ag., *P. linearis* Grev. and *P. leucosticta* Thur. ; the Pacific species[8] were *P. perforata* J. G. Ag., *P. schizophylla* Hollenb. and *P. naiadum* And. Specimens were extracted exhaustively with boiling water, and the extracts dialysed, freeze-dried and analysed for galactose and 6-*O*-methylgalactose by quantitative paper chromatography following complete acidic hydrolysis[9], for 3,6-anhydrogalactose by a colorimetric method[10], for ester sulphate by a spectrophotometric method after destruction of organic matter with nitric acid[11], and for 'precursor ester sulphate' by measurement of the 3,6-anhydrogalactose formed on treatment with sodium hydroxide using conditions under which the polysaccharide is protected from degradation[5]. With the exception of the materials from *P. naiadum*, all the polysaccharide extracts were of similar composition, that is, they contained (i) 6–12 per cent of ester sulphate, most of this being of the 'precursor' type, (ii) 5–20 per cent of 3,6-anhydrogalactose, (iii) usually 9–27 per cent of 6-*O*-methylgalactose, although the amount of this component was occasionally as low as 3–4 per cent, (iv) about two molar proportions of galactose to every one of ester sulphate, and (v) xylose (if at all) in very small quantity. Four samples of *P. naiadum* were examined; one from the Monterey Peninsula, California, one from Friday Harbor, San Juan Islands, Washington, and two from Vancouver Island. These showed mutual resemblance, while differing from the other species, in that they contained (i) 16–20 per cent of ester sulphate, only about one-fifth of which was of the 'precursor' type; (ii) little 3,6-anhydrogalactose (< 3 per cent); (iii) no detectable amount of 6-*O*-methylgalactose (limit of detection about 2 per cent); (iv) less galactose on a molar basis than ester sulphate; (v) 10–20 per cent of the sugar units as xylose (identified by paper chromatography only).

Hollenberg[12] suggested, on other evidence, that there are sufficient grounds for removing *P. naiadum* to a different genus, for which he has proposed the name of *Smithora*. The results described here, namely, that *Porphyra naiadum* differs in certain of its carbohydrate components from other species of *Porphyra*, appear to support this suggestion.

Detoxications of Aromatic Acids with Glutamic Acid and Arginine in Spiders

THE presence of detoxication mechanisms in insects is now well known, and some of these are of significance in the phenomena of resistance to, and selective action of, insecticides[1]. Arthropods, other than insects, are also the object of attack by insecticides for medical or economic reasons, but virtually no information is available on the fate of such foreign organic compounds in these other invertebrates.

Table 1. R_F VALUES AND IONOPHORESIS OF SOME AROMATIC ACIDS AND METABOLITES

† In 0.02 *N* sodium hydroxide for 2 hr. at 10 V./cm.

It was of interest, therefore, to look for detoxication mechanisms in arthropods and compare them with analogous processes in other organisms. *p*-Amino- and *p*-nitro-benzoic acid have been used as test substances since their fate in other animals is well known, and conjugates of these compounds may be easily detected by their reaction with dimethylaminobenzaldehyde, either directly or after treatment with titanous chloride.

When house spiders (*Tegenaria* sp.) were injected with *p*-aminobenzoic acid and their excreta examined on paper chromatograms, three major metabolic products could be detected. One of these was identified as *p*-carboxyphenylsulphamic acid by its delayed action with dimethylaminobenzaldehyde and acetic acid, by its identity with the synthetic reference compound on paper chromatography, and by comparison with the reference material on ionophoresis (Table 1). Acid hydrolysis of eluted zones gave SO_4^{2-} and *p*-aminobenzoic acid.

A second metabolite was thought to be *N*-*p*-aminobenzoylglutamic acid, since it had identical behaviour with synthetic reference material on paper chromatograms and on ionophoresis. Eluates of paper chromatograms showed an absorption maximum at 272 mμ in 0.1 *N* sodium hydroxide, similar to that of *p*-aminobenzoic acid and its conjugates. Acid hydrolysis of such eluates gave *p*-aminobenzoic acid and glutamic acid. Measurement of the fluorescence–*p*H curve[2] gave an apparent pKa_1 of 3.2, identical with that of authentic *p*-aminobenzoylglutamic acid, but differing from those of *p*-aminobenzoylglucoside (1.9) and *p*-aminobenzoic acid (4.5) determined similarly.

A third metabolite is believed to be α-*p*-aminobenzoylarginine, since it had identical behaviour with this compound on electrophoresis and on paper chromatograms. It gave an intense Sakaguchi reaction, and acid hydrolysis of eluates of chromatograms yielded *p*-aminobenzoic acid and arginine. These eluates had a light absorption with a maximum at 272 mμ in 0·1 *N* sodium hydroxide.

Small amounts of *p*-aminobenzoylglutamine were also detected in the excreta by paper chromatography and ionophoresis.

In similar experiments with *Tegenaria*, in which *p*-nitrobenzoic acid was injected, conjugates of glutamic acid, arginine and glutamine with *p*-nitrobenzoic acid were also excreted and identified as above. No reduction of the nitro group was observed.

Other spiders (*Agelena, Lycosa, Epeira* sp.) yielded similar conjugates when dosed with *p*-aminobenzoic acid, but relatively greater amounts of the glutamine conjugates were excreted by *Epeira*, the large garden spider.

A variety of amino-acids may be encountered in the peptide conjugation of foreign aromatic acids[3], but the most widely found reaction is with glycine to form hippuric acids These take their general trivial name from benzoylglycine (hippuric acid), which was first found in the urine of horses A similar process leads to the formation of ornithine derivatives, the so-called ornithuric acids, in some birds[4] Using similar terminology, the excreted glutamic acid conjugates in spiders could be termed arachnuric acids

Experiments (unpublished observations) with other arthropods dosed with *p*-aminobenzoic acid have given no indication of the presence of glutamic acid conjugates Millipedes, centipedes and harvest spiders dosed with *p*-aminobenzoic acid yield a product chromatographically similar to α-*p*-aminobenzoylarginine, and the crustacean woodlouse (*Armadillidium* sp) converts *p*-aminobenzoic acid to the corresponding glycine derivative

Reversible Inactivation of Acid Phosphatase in Human Prostatic Fluid

FOLLOWING our demonstration that the 'acid phosphatase', in human prostate homogenates, is incompletely and reversibly inactivated by incubation in the presence of calcium ions[1–3], we have confirmed the same reversible inactivation in the fluid obtained by massage of the prostate of individuals with normal prostates The methods used have been described in our previous publications Table 1 gives the results obtained in nine experiments on nine different prostatic fluids. The results are expressed as a percentage of a calculated initial value of 100 As compared with the original values, incubation in the absence of calcium ions resulted in little inactivation (mean 11 4) while, in the presence of calcium ions, inactivation amounted to a mean value of 52 6 per cent When the concentration of calcium ions was increased to 12–18 mgm per cent, inactivation was increased to a mean value of 81 9 per cent

At the end of the incubation in the presence of calcium ions, the partially inactivated samples were deprived of calcium ions by the addition of 'Versene' and further incubated for a period of 60 min This resulted in a partial but definite regeneration of the acid phosphatase activity, which rose from a mean of 18 1 per cent of the original activity to a mean value of 58 5 per cent It is possible that regeneration might proceed further if incubation were prolonged beyond 60 min

Table 1 PROSTATIC FLUID ACTION OF CA^{++} ON ACID PHOSPHATASE

Exp No	Initial value†	Values after incubation*			Reactivation‡ ('Versene')
		Ca^{++} free ('Versene')	Ca^{++} 2–8 mgm per cent	Ca^{++} 12–18 mgm per cent	
1	100 (432)	81	—	10	71
2	100 (5,150)	70	56	14	47
3	100 (1,130)	100	78	58	87
4	100 (4,400)	95	61	36	79
5	100 (6,220)	106	19	1	47
6	100 (1,200)	97	71	29	73
7	100 (3,530)	86	54	9	65
8	100 (3,130)	84	67	3	26
9	100 (3,970)	79	21	3	32
		Mean 88 6	Mean 47 4	Mean 18 1	Mean 58 5

* 90 min at 37° C

† The number between parentheses is the actual value, in Bodansky units per ml

‡ 60 min at 37° C after inactivation

These results confirm the fact of the reversible inactivation by calcium ions of the prostatic acid phosphatase previously established under different experimental conditions and indicate that this inactivation can be produced in normal prostatic fluid as well as in homogenates of the organ

Stimulation of Cell Locomotion and Pseudopod Formation by Heparin

IT has been suggested[1,2] that mucopolysaccharides play a part in cell surface extension and mobility During an investigation of pseudopod formation and chemotaxis in *Amoeba proteus*[3] it has been found that heparin (U S P , Light's Chemical Co) can stimulate the formation of pseudopods when a fine pipette containing 3 × 10^{-5} molar heparin, dialysed against Chalkley's medium, is held near an amœba (Fig 1 *A–E*) Calculation shows that under these conditions the initiating concentration when the amœba is 50μ away from the pipette is approximately 5 × 10^{-7} molar When the pipette contains 10^{-4} molar heparin active pseudopods are quickly inhibited and the amœba reverses away from the pipette Pipettes containing Chalkley's medium, agar, or various concentrations of sucrose do not stimulate or inhibit pseudopod formation There is a mechanical inhibitory effect if fluid is passing rapidly out of the pipette, but this is avoided by using fine pipettes, 10–15μ in diameter, or by making up the solutions in 0 5 per cent agar jelly Glass pipettes held within 1 or 2μ of an amœba will often induce blebs but these do not develop into pseudopods The stimulation of pseudopods by heparin is effective at pipette to amœba distances of the order of 50μ The material in the pipette reaches the amœba by diffusion and not by ejection

It has recently been shown that the anterior portion of an advancing amœba is depolarized, and this fact has been incorporated in a theory of amœboid movement[4]. In an investigation, to be reported elsewhere[5], it has been found that heparin and some other natural mucopolysaccharides also depolarize the amœba membrane, and it is likely that this is the basis of pseudopod stimulation by heparin A derangement of mucopolysaccharide metabolism has been suggested as possibly implicated in malignancy[1] and it may be that malignant cells are those cells the surface membranes of which are by reason of a modification of their composition more easily depolarized by compounds such as heparin normally occurring in body fluids Leucocytes would be cells easily depolarized by heparin-like substances in their natural environment There seem to be two alternative mechanisms

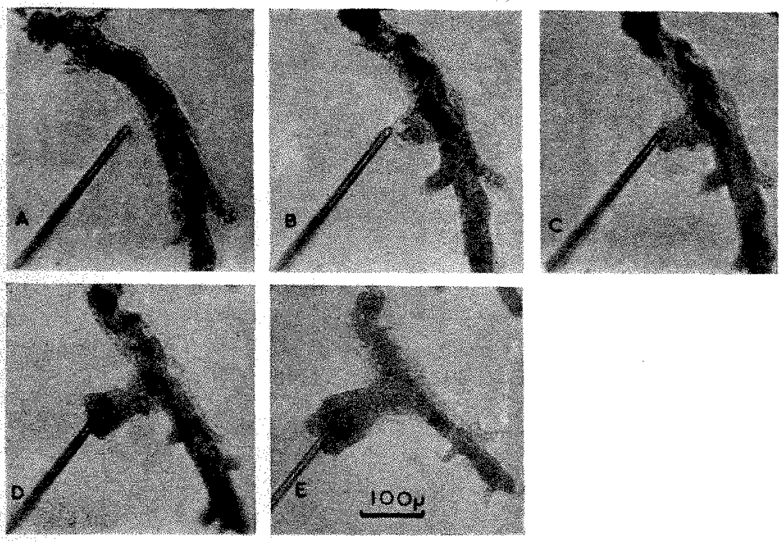

Fig. 1. *A–E*, *Amoeba proteus* in Chalkley's medium. The pipette contains 3×10^{-4} molar heparin, dialysed against Chalkley's medium

(*a*) Normal cells are inhibited by the normal physiological concentrations of heparin-like substances, and malignant cells are less sensitive and so are not inhibited by the normal concentrations. (*b*) The normal level of heparin-like substances is not sufficient to stimulate movement in normal cells, but is sufficient to stimulate the more sensitive malignant cells.

The facts and analysis presented here suggest that compounds such as basic proteins or basic polypeptides which combine with the active groups of mucopolysaccharides may be effective in inhibiting cell movement. This possibility is being investigated in this laboratory. Further work is in progress in the hope of elucidating the action of heparin on pseudopod formation and locomotion.

Species of Siphonaptera from a British Otter

Siphonaptera have been recorded from the majority of the British wild mammals[1,2]. However, there are several notable exceptions and these are the Cetacea; the Pinnipidea; the Ungulata, with the exception of *Dama dama* L., and the following species: *Myotis bechsteini* Kuhl, *Myocastor coypus* Mol. and *Lutra lutra* L.

On the evening of August 24, 1961, a dead female otter (*Lutra lutra* L.), which was still warm, was found on the road at Faoilean, near Torrin, Isle of Skye. It had been killed presumably by a motor vehicle. The animal was placed in a new polyethylene bag which was then sealed. Because of various circumstances it was not examined until three days later, when a single dead flea was found on the inside of the bag. This flea was a female specimen of *Spilopsyllus cuniculi* Dale. So far as is known, this is the first time that a flea has been collected from a British otter. The principal host of this flea is *Oryctolagus cuniculus* L., although it has been recorded on many other wild mammals including: *Apodemus sylvaticus* L., *Arvicola terrestris* L., *Clethrionomys glareolus* Miller, *Dama dama* L., *Felis silvestris* Miller, *Lepus europaeus* de Winton, *Mustela erminea* Barrett Hamilton, *Mustela putorius* Pocock, *Sciurus carolinensis* Gmelin, *Sorex araneus* Jenyns and *Vulpes vulpes* Bechstein.

The absence of fleas on the Cetacea, which frequent the open seas and are only found on dry land when stranded, is understandable. This is more or less true for the Pinnipidea, because even though they frequent the shores of Britain they never travel far from the sea when on the land. However, it is quite likely that they harbour fleas from time to time. The absence of records from all but one of the Ungulata, and the three species mentioned here, are no doubt because of the lack of investigation, due to various reasons such as rareness or inaccessibility of the species. In time, no doubt, various species of Siphonaptera will be found on all these mammals.

The flea has been placed in the British Museum (Natural History).

Culture Methods as an Aid to Experiment on Reptile Embryos

Little progress has been made in the application of experimental techniques to reptilian embryology. Panigel[1], however, found that the eggs of the common lizard (*Lacerta vivipara*) could be removed from the mother and cultured in Petri dishes containing cotton wool moistened with saline. He also found that development was more rapid at 27° C. than at room temperature. We have been able to extend these observations and to show that the method has promising applications to future experimental work.

Pregnant females of *Lacerta vivipara* usually contain 5–8 fertile eggs. In 1961 we obtained a total of 122 eggs from lizards taken in the mating season (late April to early June). Of these 93 developed successfully in culture and were kept at various temperatures for periods of 5–40 days. The youngest embryos were at a stage of development corresponding approximately to that of a chick embryo at stage 19 (3–3½ days) in the table given by Hamilton[2] when culture began. Because we wished to investigate several different embryological problems, the embryos were treated in a variety of ways so that an accurate statistical analysis of temperature effects is not possible. The following examples, however, illustrate the effect of high and low temperatures on the rate of development.

First, sibling embryos *a*, *b*, *c*, *d* and *e* were put up in culture at a stage comparable with a stage 19 chick. *a* was cultured for 11 days at 4° C. and 1 day at room temperature (21°–23° C.), and showed no appreciable development: whereas *b*, cultured for 13 days at room temperature, reached the equivalent chick stage 27: *c* and *d* were both cultured for 21 days; *c* was kept at room temperature throughout, but *d* was kept for the first 11 days at 4° C. and then transferred to room temperature: *c* and *d* reached equivalent chick stages of 34 (8 days) and 26 (5 days) respectively: *e*, cultured at room temperature for 40 days, was fixed just before hatching.

Secondly, sibling embryos *f*, *g*, *h*, *i*, *j* and *k* were put up at a stage comparable with chick stage 21: *f*, *g* and *h*, cultured for 9, 23 and 30 days respectively at room temperature, reached equivalent chick stages of 29, 36 and 38: *i* showed no appreciable development after 9 days at 4° C., and *j*, also at 4° C., only reached the equivalent chick stage of 22 after as long as 23 days. On the other hand, *k* reached the equivalent chick stage of 34 after only 8 days of culture at 30° C.

Comparable results were obtained with several other batches of embryos. The 10 embryos kept for some period at 30° C. all showed accelerated development. Conversely, 20 embryos showed an almost complete arrest of development while they were kept at 4° C., although they survived at this temperature for periods of up to 29 days. When some embryos were transferred to room temperature apparently normal development ensued. This finding may have practical significance, since it suggests that large numbers of embryos can be stored at a minimal rate of development until it is convenient to operate on them.

It was found both by Panigel and ourselves that even in embryos kept at room temperature there was considerable mortality around the time of hatching, although up to this point few deaths occurred. None of our embryos kept at 30° C. succeeded in hatching, although some reached near-hatching stages. A few embryos were also kept at 33°–35° C. These failed to survive for longer than about 10 days, but with more stringent precautions against dehydration longer survival might have been obtained.

Operations involving the cutting off of a portion of tail with fine scissors, after making a small cut in the thin shell membrane and underlying embryonic membranes, were carried out on 16 embryos kept at room temperature. These embryos were all at a comparatively late stage of development equivalent to chick stages of 23 (4 days) or later. Only 2 embryos died as an apparent direct result of the operation, the remainder being fixed 5–27 days afterwards. Some of these prolapsed through the rent in their membranes, which appeared to form adhesions with the surface of the body.

In certain cases the results of the operation were difficult to interpret and the tissues near the lesion were disorganized. In other embryos no such complications ensued. None of the embryos showed any obvious signs of tail regeneration although the wound had healed. In some, however, histological examination revealed certain features suggestive of those described in early tail regenerates of geckos by Hughes and New[3]. The apparent lack of tail regeneration in our specimens is of interest and deserves further investigation. It may have been due simply to inadequate survival time, but there are other possible explanations; for example, the power of tail regeneration so characteristic of the adult may not develop until post-natal life.

It was also found possible to culture the eggs of the slow-worm (*Anguis fragilis*), another viviparous species[4]. Temperatures of about 18° C. seemed to be most suitable for their maintenance. Removal of part of the tail was also carried out on 3 late slow-worm embryos; these showed no obvious external signs of regeneration a month after the operation but have not yet been studied histologically.

These observations suggest that Panigel's technique offers a new approach to the problems of experimenting on reptile embryos, and particularly to the study of morphogenesis and regeneration during the later stages of development.

Bivalved Gastropod from Jamaica

THE bivalved gastropod *Berthelinia* Crosse (= *Tamanovalva* Kawaguti and Baba) has been reported from Japan[1], Australia[2], and California[3]. A second genus, *Midorigai* Burn, has been described from Australia. The purpose of this communication is to record *Berthelinia* from Jamaica. The first specimen was found on *Caulerpa verticillata* Agardh growing on rocks in an open part of a mangrove channel near Port Royal on January 8, 1962. Small quantities of algæ collected on January 11 and 16 yielded fifty more specimens, so in this small area *Berthelinia* can be described as common. To my knowledge, this is the first time that living bivalved gastropods have been taken from the Atlantic.

The shell is almost identical with that of *B. typica* Gatliff and Gabriel[4]. The present species certainly belongs to this genus, although further work is necessary to decide whether or not it is distinct from those species already described.

I thank Prof. D. M. Steven and the staff of the Department of Zoology, University College of the West Indies, for provision of laboratory facilities, and the Department of Scientific and Industrial Research and the Committee for Commonwealth University Interchange for funds while in Jamaica.

Occurrence of *Cystoseira tamariscifolia* (Huds.) Papenf. on the West Coast of Scotland

Cystoseira tamariscifolia (Huds.) Papenf. is generally regarded as characteristic of warmer seas, being particularly abundant on the Atlantic shores of Europe and North Africa and in the Mediterranean[1]. In the British Isles it is frequent on the south-west of England and on the south and west coasts of Ireland[2], extending on occasion to Co. Donegal[3] and Co. Antrim[4]. It has rarely been recorded from Scotland: early records exist from the coasts of Ayrshire and

Kintyre[5] while from the Island of Barra in the Outer Hebrides a single specimen in the drift[6] and one or two dredged specimens[3] have been recorded.

While making a survey of the inter-tidal algae of Barra in July 1961, particular attention was paid to the presence of *Cystoseira*, and near Cliad on the west coast of the Island an abundant growth of *Cystoseira tamariscifolia* was found. The plants were growing in deep tidal pools at a level near mean low water of spring tides and were associated mainly with *Codium fragile* subsp. *atlanticum* and *Halidrys siliquosa*. They ranged from 10 to 25 cm. in height, formed bush-like tufts in the water and showed the marked iridescence normally associated with this species. Several days later, following a severe gale, large quantities of *Cystoseira tamariscifolia* were found in the drift at many localities on the west coast of the Island, suggesting that an abundant growth may occur at sub-littoral levels.

In view of the range in size and the numerous receptacles found on the plants it is likely that this species is vigorously multiplying and that it is present on other Hebridean Islands. This latter suggestion is supported by the finding of fresh drift specimens of this alga on the west coast of Rhum[7] in August 1961. Any further records of *Cystoseira tamariscifolia* from Scotland will be welcomed.

I thank Dr. Helen Blackler of the British Phycological Society's Check-list Committee for confirming my identification of the species.

An Annelid Proprioceptor

The structure of the worm *Harmothöe* is in most respects typical of errant polychætes; it has well-developed parapodia armed with bristles and provided with dorsal and ventral cirri, but on the dorsal side of the worm are scales (elytræ) which most polychætes do not have. Methylene blue preparations reveal the following types of sense organs: (*a*) numerous small bipolar cells of ventral cirri and of the elytræ; (*b*) a group of bipolar cell bodies with branched endings in the region where the bristles emerge from the parapodial cuticle; (*c*) numerous and scattered bipolar cells beneath the cuticle particularly on the ventral side of the body; (*d*) bipolar cells of the elytræ; (*e*) concentrated groups of bipolar cells standing at right-angles to the surface in the thickness of the epithelium; (*f*) several bipolar cells each with a long dendrite stretched diagonally across the ventral side of every parapodium. Types (*a*), (*c*) and (*e*) are described by Smith[1].

No other type of peripheral neurone is found and each of the peripheral sensory cells appears to send an axon the whole way to the central nervous system. There is no trace of a peripheral nerve net or running together of axons.

Recording externally from the sensory axons reveals that types (*b*), (*c*) and (*f*) include mechanoreceptors. Types (*a*), (*d*) and (*e*) have not been investigated because of technical difficulties in recording their responses. The group (*b*) are sensitive to any touch of the bristles and respond with an adapting discharge. Of the type (*c*) cells scattered over the body, many, and perhaps all, respond to touch or strain of the cuticle. Most notable of all, large bipolar cells (*f*) respond to strain of the cuticle of the base of the parapodium and hence to any parapodial movement, passive or active. They are therefore proprioceptors. Their responses are readily recorded as large spikes after eliminating the bristle responses by pulling out the bristles. A mechanical deformation of 100μ can be applied by a small stylus on the region occupied by the dendrite of the bipolar cell shown in Fig. 1. A maintained sudden stretch of the dendrite causes a discharge of impulses in the axon of the long bipolar cell, with adaptation over the course of a few seconds. The impulses are thus identified with the (*e*) neurones. The size and regular arrangement of the latter in every segment also suggest their function as proprioceptors.

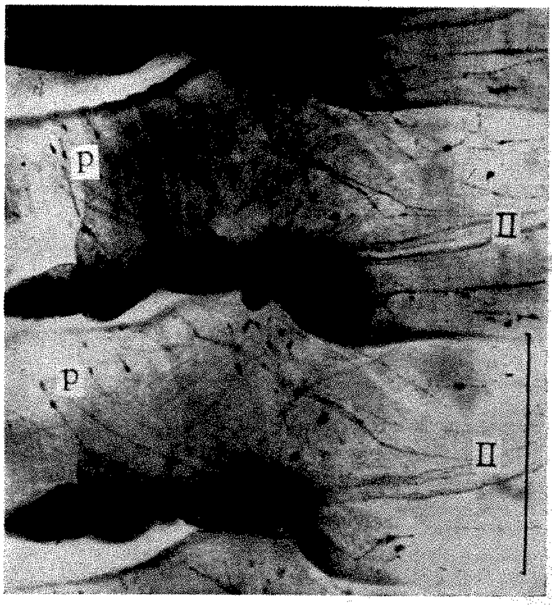

Fig. 1. Bipolar proprioceptor cells (*p*) lying in the cuticle across the ventral side of two adjacent parapodia of *Harmothöe*. Some of the axons of the parapodial nerve (II) are also shown. Anterior is at the top. Scale, 1 mm.

A proprioceptor which adapts so quickly can scarcely be effective in co-ordination of the initial direction of the movement when a resting animal begins to move. One can readily observe how a worm modifies its parapodial posture to suit the irregularities of the substrate, but no evidence has ever been produced to suggest that the basic sequence of locomotory movement is co-ordinated by proprioceptors in polychætes. It has been found that injection of liquid paraffin into the parapodial cavity, or local cuts in the area of the proprioceptors, alter neither the fundamental sequence of movement of the operated parapodium, nor its relationships with the movements of neighbouring segments. The conclusion is therefore that the main sequence of movements is centrally controlled, though it can be appropriately modified in detail by mechanoreceptors of the body wall including proprioceptors of the parapodia.

ENTOMOLOGY

Artificial Feeding and Rearing of the Aphid, *Myzus persicae* (Sulzer), on a Completely Defined Synthetic Diet

SINCE the classic study of Hamilton[1] in 1935 on the artificial feeding of *Myzus persicae* (Sulzer), many attempts have been made to feed and maintain various aphid species on gels, or on liquids, sometimes under pressure, accessible to the insects via various natural and artificial membranes[2–8]. Although limited uptake of some fluid was demonstrated or could be inferred from slight increases in the survival of the aphids in these studies, no instances of prolonged survival, growth or of development have been reported.

We have also found that *M. persicae* ingests sugary fluids via a membrane. These solutions, with and without neutral red or phosphorus-32 as indicators of uptake, were presented to the aphids in simple cages or in choice-chambers, with the fluids above a membrane of stretched 'Parafilm'—a waxy material made by Marathon, American Can Co., Menasha, Wisconsin. We have been able to demonstrate greater rates of feeding, survival, and nymphal production of aphids fed on 10–20 per cent sucrose solutions, which were also those preferred by *M. persicae*, than on concentrations outside this range. Maintenance of body-weight, the production of salivary sheaths and of honeydew droplets were further found to be related to uptake.

In one experiment with 60 apterous adult *M. persicae* per treatment, the 50 per cent survival-time was 3·5 days on water only, 6·5 days on an 18 per cent sucrose solution and 13 days on a completely synthetic diet having the composition given in Table 1. The average number of nymphs produced per adult was 5 on water, 9 on the sucrose solution, and 19 on the nutrient diet.

Table 1. COMPOSITION OF THE LIQUID DIET FED TO *Myzus persicae*

L-Amino-acids and amides* (mgm.)		Vitamins* (mgm.)	
Alanine	100	Thiamin	2·5
Arginine	270	Riboflavin	2·5
Asparagine	550	Nicotinic acid	10·0
Aspartic acid	140	Pyridoxine	2·5
Cysteine	10	Folic acid	0·5
Glutamic acid	140	Calcium pantothenate	5·0
Glutamine	150	Meso-inositol	50·0
Glycine	40	Choline chloride	50·0
Histidine	40	Biotin	0·1
Isoleucine	30	Ascorbic acid	100·0
Leucine	40		
Lysine	120	Sucrose	18 gm.
Methionine	10	K_3PO_4	500 mgm.
Phenylalanine	10	$MgCl_2.6H_2O$	200 mgm.
Proline	40	Cholesterol	20 mgm.†
Serine	80	Water (to make)	100 ml.
Threonine	140	H_3PO_4 (to give)	*p*H 7
Tryptophan	40		
Tyrosine	40		
Valine	40		

* Relative amounts of amino-compounds and of vitamins based on analyses of pea juice (ref. 9) and on those found satisfactory in locust nutrition (ref. 10), respectively.

† Approximate amount dissolved by boiling in water.

Appreciable numbers of honeydew droplets were excreted by the adult aphids and by their progeny when fed on the 18 per cent sucrose solution and on the diet.

Seventy-one nymphs born to the experimental adults feeding on the diet were in turn confined on a membrane with access to the diet. More than 50 per cent survived for two weeks, during which time all moulted at least twice. Of 40 which survived 16–17 days, 11, 14 and 7 had developed into diminutive fourth instar apterous and alatiform nymphs and apterous adults, respectively.

Improvements clearly need to be made in the chemical and physical properties of the membrane-diet system before rates of feeding, growth, development and reproduction normal for the aphids on their host plants may be reached. However, the limited successes so far achieved indicate the immediate practicability of the artificial feeding method for nutritional and behavioural studies *per se*, as well as for other investigations, such as of form determination and of virus transmission phenomena, which would be facilitated greatly by a prolonged maintenance of aphids divorced from their host plant.

Mosquito Attraction and Repulsion

THERE is uncertainty in the literature as to the exact signals and responses that guide mosquitoes to a warm-blooded host[1]. Reports of specific chemical attractants (for example, lysine[2]) lack confirmation.

Our experiments indicate that *Aedes aegypti* can be steered almost quantitatively to a target, provided: (1) they are activated by breath or carbon dioxide (this is mainly non-directional); and (2) the target is both wet and slightly warm[3]. Some experiments were made in a wind tunnel 2 × 2 × 10 ft. long with air at about 28° C. and 25 per cent relative humidity moving at about 0·5 ft./sec. About 18 in. from the upstream end, three targets were presented, each a cylinder 3 cm. in diameter and 7 cm. long, covered with black woollen cloth and warmed if required (usually to about 35° C.) by an internal heating element. About 25 adult, female *Aedes aegypti* were placed in the tunnel and given at least a day to acclimatize, with water and sugar provided, but no previous blood meal. If human breath or carbon dioxide was suddenly added to the air stream, the insects flew actively and continued to do so for several minutes.

Under these conditions, the number of insects alighting on each target was counted during three 5-min. intervals with the results shown in Table 1.

Table 1. NUMBER OF ALIGHTMENTS

Interval	1	2	3	Total
Warm, wet target	157	103	98	358
Cold, wet target	12	3	7	22
Warm, dry target	2	1	4	7

In other experiments, a stream of warm, humidified air was released into the air stream from a slit. By adding a little inert smoke the location of the 'convection current' could be made visible. Fig. 1 is a time

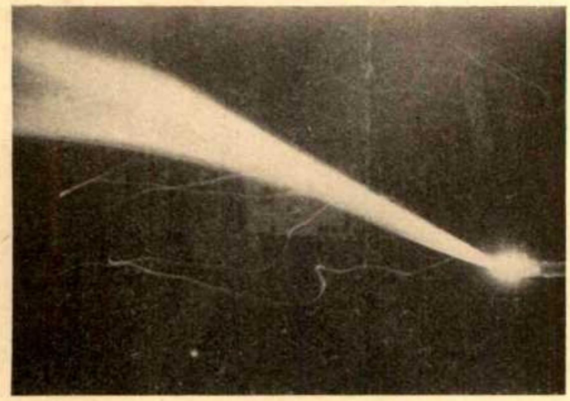

Fig. 1

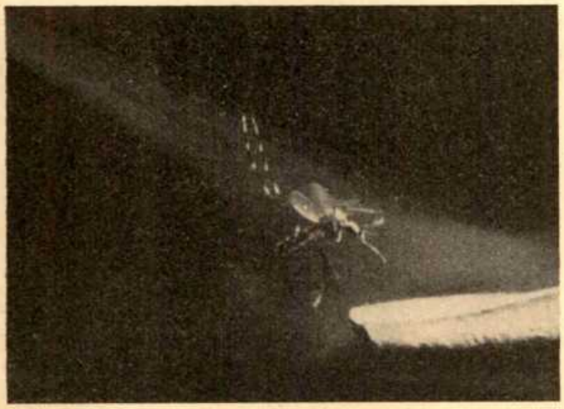

Fig. 2

exposure with dark-field illumination, which shows the tracks of several mosquitoes entering the stream and flying down it to the target. Fig. 2 shows an insect about to alight after having homed in in this way.

These experiments confirm previous reports that warm, wet convection currents play a principal part in guiding *Aedes aegypti* to their hosts[1,3–5].

It follows that the insects must have a sensory organ capable of detecting such currents. In view of the transitory structure of the currents and the flying speed of the insects, the sensing organ must have a very short time constant. The transfer of energy to it is therefore most probably radiative, in which case it will involve the infra-red properties of water vapour, and in particular the far infra-red frequencies which are the only ones that can be activated by collision at ambient temperatures[6].

On the assumption that mosquito repellents interfere with this guidance mechanism, the far infra-red absorption spectra in the 15–36μ region of five commonly used mosquito repellent chemicals were examined in a Perkin–Elmer model 21 spectrophotometer equipped with a cæsium bromide prism. The results are shown in Fig. 3, with the absorption spectra of water vapour and of three non-repellent chemicals included for comparison. (Propylene glycol was run as the pure liquid, the rest as dilute solution in *cyclo*hexane).

There are distinct indications of correlation.

It is not yet known how the repellent interferes with the perception of humid convection currents, but in general anything that would interfere with the radiative transfer of energy would leave only the slower conductive processes to operate and would increase the time-constant of the detector.

This suggestion also accounts for the otherwise curious report[4] that vapours of gasoline and ether are attractive to certain kinds of mosquito. These liquids combine a high volatility with a high molecular weight and thereby bring about a localized reduction in thermal conductivity of the air. A flying mosquito would lose its metabolic heat more slowly in such regions, and this could engender a sensation somewhat similar to that from a warm, moist convection current.

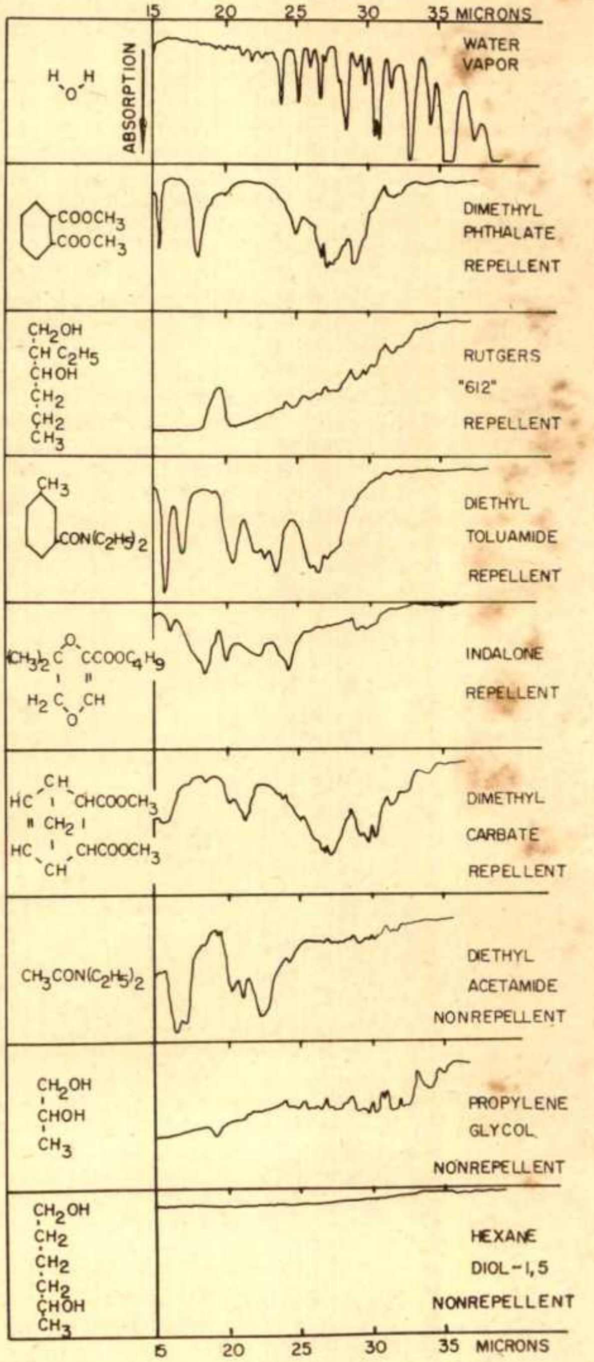

Fig. 3

The guidance system here proposed is naturally incomplete. It takes no account of the effects of target colour and movement, and it does not embrace the fact that when caged mosquitoes are exposed to repellents like dimethyl phthalate or 2-ethylhexane-diol-1,3 they are very difficult to activate by breath or carbon dioxide.

Nevertheless, if the basic requirement for repellency to *Aedes aegypti* is a particular kind of far infra-red absorption spectrum, this is a mechanical rather than a chemical property, and it follows that intrinsic repellency may be looked for in a compound of any chemical class, provided only that the molecule is made up of the right combination of mass-points and elastic forces. If this is so, then the way is open to a rational search for new mosquito repellents, including repellents to be taken by mouth and excrete through the skin.

In case it is thought remarkable that mosquito repellency should be connected with so commonplace a property as a rather general absorption of infra-red radiation beyond about 25μ, it must be remarked that more than a third of the many thousands of chemicals evaluated as repellents at the Orlando Laboratory of the U.S. Department of Agriculture were found to have some repellent properties[7].

We thank Dr. P. N. Daykin for discussions and the Canada Department of Agriculture for a grant which made this study possible.

MICROBIOLOGY

Antifungal Activity of *Cylindrocarpon radicicola* Wr.

DURING investigations into the mycorrhizal tuberous roots of the saprophytic orchid *Dipodium punctatum* R. Br., the surface flora of washed root portions were sampled according to the method of Harley and Ward[1]. Isolates from plants of one particular location frequently included a species of *Cylindrocarpon*, afterwards identified as *C. radicicola* Wr.

The accidental contamination of plate culture of this fungus by *Aspergillus niger* revealed that the *Cylindrocarpon* was strongly antagonistic towards this species. Mycelial extension of *A. niger* was inhibited in the proximity of the *Cylindrocarpon* colony. Microscopic examination showed abnormal proliferation of the terminal hyphæ similar to that described by Aytoun[2], as an effect of griseofulvin on *Botrytis* spp.

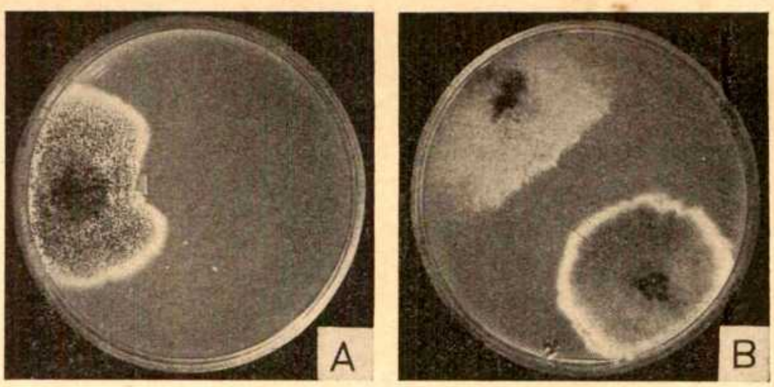

Fig. 1. *A*, Growth of *Aspergillus niger* being inhibited by a sterile agar block removed in front of a colony of *Cylindrocarpon*; *B*, *C. radicicola* inhibiting radial growth of *Botrytis cinerea*

To test the hypothesis that this was caused by an antagonistic substance diffusing ahead of the growing *Cylindrocarpon* colony a small block of agar was cut from a plate culture 1 cm. in front of the advancing mycelium and placed next to a colony of *A. niger* on another plate. The hyphæ of *A. niger* adjacent to the block showed similar microscopic abnormalities and macroscopic evidence of inhibition to those caused by living *Cylindrocarpon* (Fig. 1).

A selection of 66 fungal species, representing the major taxonomic and ecological groupings, were then tested against the *Cylindrocarpon* by simultaneously inoculating opposite sides of agar plates with *Cylindrocarpon* and the test fungus. Suppression of radial growth was used as a simple measure of fungistatic activity. Forty-eight species of 34 genera from all major taxonomic and ecological groups were inhibited. Most of these fungi were extremely sensitive; very few showed intermediate effects. Some of the parasitic and saprophytic species antagonized by *C. radicicola* are listed here: *Alternaria solani* (Ell and G. Martin) Son; *Cercospora viticola* (Ces) Sacc.; *Gibberella fujikuroi* (Saw). Wr.; *Helminthosporium sativum* Pamm. King and Bakke; *Mycosphaerella pinodes* Berk and Blox; *Phoma citricarpa* McA.; *Penicillium notatum* Westling; *Pythium ultimum* Trow; *Schizophyllum commune* Fr.; *Trichoderma viride* Pers. and Fr.

Filtrates from various liquid culture media on which the *Cylindrocarpon* had been successfully grown were also tested for activity. Antibiotic assay disks were dipped into the filtrates and placed on to agar plates seeded with conidia of *A. niger*, a zone of inhibition surrounding the paper disks gave evidence of inhibition of germination and the size of the zone could be used as a measure of fungistatic activity. Other fungi used in this test were *Botrytis allii*, *B. cinerea* and various species of *Penicillium*, all of which showed inhibition of spore germination. Six bacteria and three yeasts were also tested, but the culture filtrate had no effect on the growth of these organisms.

Interesting and potentially useful properties of the fungistatic substance in the culture filtrate were found to be: tolerance to a wide range of *p*H conditions, and extreme heat stability; at *p*H 8·2 the culture filtrate showed no loss of activity after autoclaving at 15 lb./2 in.^{2} for 30 min. These properties, combined with such a broad spectrum of fungistatic activity, warrant further investigation, which is now proceeding and will be reported elsewhere in due course.

A culture of *C. radicicola* obtained from the Commonwealth Mycological Institute, Kew (71577), was shown to have this same antifungal activity, but one obtained from the Centraalbureau voor Schimmelcultures, Baarn, did not. It is interesting in this respect that the local strain and that from Kew coincide in producing a characteristic deep reddish pigment when grown on Czapek–Dox agar while the culture from Baarn lacks this.

This work was carried out while one of us (G. A. C.) held a Commonwealth Scientific and Industrial Research Organization research studentship, and one of us (G. E.) held a Wheat Industry Research Fund studentship.

Lysogenic Conversion in *Staphylococci*

Bacteria carrying a prophage generally differ from the parent strain in one or more properties[1]. The presence of the prophage may produce a new character as in *Corynebacterium diphtheriae*[2] or suppress a property of the parent strain. In *Staphylococci* resistance to erythromycin can be (inversely) related to the presence of a prophage[3]. Blair and Carr[4] have also described relationships between the presence of a prophage and penicillinase or α-toxin production. In our case, lysogenic conversion of *Staphylococci* to loss of β-toxin production is reported. Strain 879 (phage pattern, 3^B, 3^C, 55, 71) is a non-lysogenic strain producing α- and β-toxin (hæmolysin). The phages were derived from staphylococcal strains of phage group II (ref. 5) and propagated on strain 879.

Strain 879 was lysogenized with sixteen phages by spotting the phages on indicator plates, isolating the secondary growth and testing for lysogenicity and immunity by cross-streaking. In eleven cases the lysogenic strains produced only weak hæmolysis on sheep blood. The phages producing this 'conversion' were serologically related (group *F*). No conversion was obtained with the standard phages of group II.

The obligatory relation between lysogenicity and hæmolysis was established in more quantitative experiments. Phage and bacteria were mixed in suitable concentrations, incubated for 5 min. to permit adsorption, centrifuged, and the number of bacteria and plaque-forming units determined in supernate and sediment. Some examples are given in Table 1.

Hæmolysis of survivor colonies was scored on blood-agar plates. Lysogenicity was scored by replicating from the blood-agar plates on indicator plates or by cross-streaking individual colonies. All weakly hæmolytic colonies proved lysogenic. The inverse was not always true. Some fully hæmolytic colonies yielded phage. It was shown by plating out and cross-streaking that these colonies were mixtures of lysogenic (weakly hæmolytic) and non-lysogenic cells. They could have originated from small clumps with a minority of lysogenic cells or, more probably, from late infection of the colonies on the plate with carry-over phage as the phenomenon was always more pronounced in experiments with high multiplicity and could be reduced with antiphage serum.

The fraction of lysogenized survivors increases with multiplicity. However, even with low multiplicity, the rare lysogenic colonies always proved weakly hæmolytic (if a converting phage were used).

The possibility was considered that weakly hæmolytic variants would occur in the parent strain and that the phenomenon was due to *preferential lysogenization* of the minority variant. Spontaneous weakly hæmolytic variants occurred indeed in the parent culture. On purification the parent strain 879 and the variant (879*nH*) proved stable. Preferential lysogenization could be excluded by using purified cultures and by showing that 879 and 879*nH* were lysogenized to the same extent by phage 756 (Table 1, lines 1 and 2). Transduction by phage produced on possible weakly hæmolytic mutants in the propagating strain(s) of the phages was excluded by continual checking of propagating strains. It was, furthermore, shown that phage 756 propagated on 879 and 879*nH* in both cases produced the lysogenic conversion (lines 3, 4 and 5).

The observed conversion is due to loss of β-toxin. Strain 879 produces α- and β-toxin with marked hot–cold hæmolysis on sheep blood agar. Culture filtrates hæmolyse sheep cells to much higher titre than rabbit cells (Table 2). Anti-α-toxin neutralizes the action on rabbit cells but not that on sheep cells, which is, however, neutralized by anti-β-toxin. The lysogenized strain 879(756) produces α-toxin only and shows no hot–cold hæmolysis. The hæmolytic activity of culture filtrates is completely neutralized by anti-α-toxin and not by anti-β-toxin. The spontaneous variant 879*nH* produces mainly β-toxin, with weak action on rabbit cells. The lysogenic strain 879*nH*(756) produces no detectable β-toxin.

Lysogenic conversion to loss of β-toxin by these phages was also observed with three other strains belonging to phage group II. From some of the lysogenic strains, non-lysogenic colonies could be isolated. These reversions which had lost the phage again produced β-toxin.

Table 1

Strain	Phage	Bac./ml. $\times 10^{-7}$	Phage/ml. $\times 10^{-7}$	Per cent ads.	m*	Survivors $\times 10^{-7}$	Colonies		
							Tested	Lysogenic converted	Mixed yielding phage
879	756	7	350	83	41	0·7	81	65	—
879*nH*	756	7	350	83	41	1·2	88	74	—
879	756	11	260	78	20	1·4	37	34	—
879	756/*nH*	9	280	18	6	0·6	51	40	—

*m, multiplicity.

Table 2

Strain	Toxin titre on Rabbit cells	Toxin titre on Sheep cells
879	10	500
879(756)	10	5
879(269)	50	10
184	100	1,000
184(756)	100	10
184(184)	50	5
269	2	5,000
269(269)	2	10
879*nH*	5	200
879*nH*(756)	5	< 2

With another, non-lysogenic, β-toxin-producing strain not belonging to phage group II, no lysogenic conversion was obtained with five phages from the international standard typing set. This strain could, however, be converted with phage 756 after adaptation of this phage.

Growth of Several Strains of *Actinomyces israelii* in Chemically Defined Media

Previous work from this laboratory[1] has described a technique for obtaining uniform and quantitative inocula of the Gram-positive filamentous anaerobe *Actinomyces israelii*. It has also been shown[2-4] that the medium of Howell and Pine[5] could be simplified to give a chemically defined medium containing inorganic salts (including ammonium sulphate), glucose, glutathione, seven L-amino-acids (serine, cysteine, leucine, isoleucine, lysine, tryptophan and glutamic acid) and five growth factors (biotin, inositol, pyridoxal, nicotinic acid and riboflavin) which would support growth of a single strain of *A. israelii* in repeated serial culture. Further work[6] has described some of the chemical and physical changes which occur in a series of defined media during growth of the same Wills strain of *A. israelii*.

The results of experiments on the nutritional requirements of several other strains (Table 1), all of which were macroscopically, microscopically and physiologically typical of *A. israelii*[2,7,8] when grown in the chemically undefined medium *S* of Erikson and Porteous[7], are shown in Table 2. The culture techniques used in the present work and the visual method of assessing growth have been described elsewhere[3]. It is emphasized that previous work has involved exhaustive tests of the ability of the Wills strain of *A. israelii* to survive in various chemically defined media[2-4], or in undefined media[7], for a minimum of five sub-cultivations at 5- to 7-day intervals; in some instances this single strain has been maintained by sub-cultivation for more prolonged periods of several months or years in one or more defined media. The present preliminary results have been obtained from short-term experiments involving only a few serial transfers in any one defined medium.

Table 1. List of Strains of *Actinomyces israelii* examined in the Present Investigation together with the Donors of the Cultures and the Origin of the Cultures where known

Strain	Original donor	Site of infection and date of isolation
1934	Dr. E. Riddell	Abscess of jaw; 1950
Grant	Dr. Jacqueline Walker	Abscess of jaw; 1952
Armitage	Dr. Jacqueline Walker	Simple dermoid cyst, left rectus; 1951
Mullins	Dr. Jacqueline Walker	Abdominal sinus; 1951
Young	Dr. Jacqueline Walker	Abscess of chest (rib)
Balcome	Dr. Jacqueline Walker	Actinomycosis of jaw; 1951
Wills	Dr. Dagny Erikson	Lung lesion; 1951
Yory	Dr. Dagny Erikson	Unknown
Maslin	Dr. Dagny Erikson	Unknown
2147/52	Unknown	Unknown (about 1951)
Hyde	Unknown	Unknown (about 1951)

Of the eleven strains of *A. israelii*, all grew in the undefined media *S* or *A* (ref. 7) (Table 2). Strains 2147/52 and Hyde failed to grow in medium *HP*1, and three other strains (1394, Armitage and Mullins) survived only a few sub-cultures in this medium. All the remaining strains grew in medium *HP*1, but only strain Wills grew in the simplest medium *HP*9 tested[3]. Of the media in Table 2, all except medium *HP*9 contained oleic acid[2] and, unless otherwise indicated, all except medium *HP*9 contained starch[2]. Howell and Pine[5] believed that the sole function of starch in their medium was "to maintain non-toxic concentrations of oleic acid". The present results show that the Wills strain of *A. israelii* would grow in the presence of oleic acid (at least in medium *HP*4) whether starch was present or absent. Other results[2] showed that the same strain would grow in the presence of oleic acid and the absence of starch in media simpler than *HP*4. Strains Yory and Balcome, on the other hand, grew better when starch was present in medium *HP*4.

Table 2. Comparison of the Nutritional Requirements of Eleven Strains of *Actinomyces israelii* of Human Origin (Table 1)

Strain	Medium *S* or *A*	*HP*1	*HP*4	*HP*4 less starch	*HP*5	*HP*5 + adenine + thymine	*HP*9	*HP*9 + adenine + thymine
2147/52	(+)	(0)	(0)	(−)	(−)	(−)	(−)	(−)
Hyde	(+)	(0)	(−)	(−)	(−)	(−)	(−)	(−)
1394	(+)	(±)	(−)	(−)	(−)	(−)	(−)	(−)
Armitage	(+)	(±)	(±)	(−)	(−)	(−)	(−)	(−)
Mullins	(+)	(±)	(−)	(−)	(−)	(−)	(−)	(−)
Wills	(+)	(+)	(+)	(+)	(+)	(+)	(+)	(+)
Yory	(+)	(+)	(+)	(+)*	(+)	(+)	(0)	(+)
Maslin	(+)	(+)	(±)	(±)	(0)	(+)	(0)	(±)
Young	(+)	(+)	(−)	(+)	(+)	(+)	(0)	(Ø)
Balcome	(+)	(+)	(+)	(+)*	(−)	(−)	(0)	(0)
Grant	(+)	(+)	(Ø)	(Ø)	(−)	(−)	(0)	(0)

Incubation at 37° in liquid paraffin sealed tubes containing 2 ml. medium (refs. 2–4 and 7); subcultures carried out at seven-day intervals. (+) indicates growth in several serial sub-cultures; (±) indicates failed to survive more than one or two serial sub-cultures; (0) indicates no growth; (−) indicates not tested; (+)* grew better if starch present (ref. 2); Ø consistently gave atypical colonies (ref. 3) if carried for more than a few sub-cultures in this medium but grew typically in more complex media. The results on growth in media *A* and *S* are based on repeated serial sub-cultures over several months; some of the remaining results were obtained from a maximum of five serial sub-cultures in any one medium but the majority of the results were obtained from three serial sub-cultures in any one medium.

It has been noted[4] that growth of the Wills strain of *A. israelii* is inhibited in certain circumstances by 'growth factors' and by purines and pyrimidines; the first indication of this latter effect was obtained during the present study. On the other hand, strain Yory apparently required adenine and thymine to be added to the simplest medium *HP*9 tested (Table 2). Similarly, strain Maslin required adenine and thymine to be added to medium *HP*5, but this strain failed to grow consistently in medium *HP*9 supplemented in the same way; conversely, since medium *HP*4 = medium *HP*5 + adenine + guanine + xanthine + uracil + thymine, it may be deduced that one or more of the bases guanine, xanthine and uracil inhibited growth of strain Maslin in medium *HP*4. Strains Young, Balcome and Grant apparently required increasingly complex media in order to survive, though, as pointed out below, this is not the only possible interpretation of the results.

Since medium *HP*1 was derived[2] from the original Howell and Pine medium[5] by omission of coenzyme *A* and of citrovorum factor, it is possible that strains 2147/52, Hyde, 1394, Armitage and Mullins (Table 2) required the two missing growth factors. This has not been tested nor has a serious attempt been made to grow these strains in a variety of simpler media. It would in any case be rash to conclude from the present results that the eleven strains of *A. israelii* could be divided into two groups, one of which required coenzyme *A* and/or *citrovorum* factor, the other of which did not (Table 2). With some exceptions discussed here it is not possible from present results to state whether failure of any one strain to grow in a particular medium was due to a nutritional deficiency or to the presence of nutritional antagonists[3,4] in that medium. Nor is it possible at present to delineate the basal nutritional requirements of the species *Actinomyces israelii* although it is clear that differences exist in the precise nutritional requirements of individual strains. Detailed experiments of the kind performed for the Wills strain of *A. israelii*[2–4] are required to elucidate these points.

This work was carried out while one of us (A. O. C.) was in receipt of a Department of Scientific and Industrial Research research studentship. The eleven strains of *A. israelii* used were generously donated to one of us (J. W. P.) by Dr. Dagny Erikson.

GENETICS

Differential Response to Mutagens in *Arabidopsis thaliana*

In a series of experiments designed to look for differential response to mutagens in higher plants, more than 800 viable mutations have been induced in the crucifer *Arabidopsis thaliana* (L.) Heynh. This plant was used because of its short life-cycle of 5 weeks, its small size and obligate self-pollination. The mutants were obtained by treating seed with radiation or with mutagenic chemicals. Seed was treated in the X_1 generation and suspected mutants were isolated in the X_2 generation and confirmed as mutants in the X_3 generation. This procedure was necessary because all but one of the mutants are recessive.

The mutagens used were X-rays, X-rays plus 'Synkavit' (a methyl naphthohydroquinone phosphate, known to be a radiosensitizing chemical in tumours[1] and in barley roots[2]), tritiated 'Synkavit', ethylene imine (EI) and ethyl methane sulphonate (EMS). These were the mutagens out of 15 used initially which gave high mutation-rates—a necessary requirement when looking for specificity. EI and EMS are among the alkylating agents known to give differential gene response in *Drosophila*[3].

All mutants were grouped phenotypically into one of 27 classes. This scheme was necessarily empirical in that each class contained several morphologically distinct mutants and because a few mutants could have been placed in more than one class. If only morphologically identical mutants had been placed in any one class, there would have been several hundred classes, and the results could not have been analysed statistically. Because the number of mutants in any one cell of the table was often less than 5, a modified heterogeneity test devised by Smith[4] was used. This showed an overall significant heterogeneity at a level of $P < 0{\cdot}01$, demonstrating that there was a real differential response to the treatments. Subdivision of the table showed significant differences of $P < 0{\cdot}01$ between radiation and alkylating agents and between different concentrations of EMS. There were non-significant differences of $P > 0{\cdot}1$ between X-rays and X-rays plus 'Synkavit', between EMS and EI, between radiation doses and between dates of production of the mutants. These results, particularly the fact that the mutation spectra did not vary throughout the three years of the experiment, show that the classification scheme, although empirical, does have a logical basis.

Apart from classes where there were only few mutants, all treatments produced mutants in all classes, and differences were only of degree. The class for glabrous mutants showed the biggest differences between radiation and alkylating agents: 6 per cent of all radiation-induced mutants being glabrous as opposed to 1·2 per cent for mutants induced by alkylating agents. This gave a difference, significant at $P < 0{\cdot}001$, as evaluated by a χ^2 test. However, since the maximum mutation-rate for EMS was 85 per cent against 12 per cent for radiation, calculated as a percentage of the X_1 plants which gave viable seed, it is clear that for an equal number of X_2 progenies, more glabrous mutants will be produced by EMS than by radiation. Although methods have been calculated, for example by Bodmer[5], for testing the significance of individual classes in contingency tables, it is difficult to ascribe accurate probabilities to a table as used here, where the number of classes is large and also quite arbitrary. Thus it is not possible to state with any certainty that glabrous mutants are preferentially induced by radiation. Sufficient attention has not been paid to this factor in much of the work done elsewhere in which differential responses have been claimed.

Approximately 550 of the mutants have been examined genetically and, of these, only 80 occur at the 25 loci which have mutated more than once in all the experiments, making it impossible to demonstrate whether loci mutate differentially to different mutagens. It can be shown that 25 per cent of all radiation-induced mutants occur at these loci, whereas only 6 per cent of those induced by alkylating agents do so, indicating that alkylating agents may produce mutations at less easily mutable loci, as indicated in *Drosophila*[3].

These results from more than three years of continuous production of mutants in *Arabidopsis* show that although there are differences in the types of mutations produced by radiation as compared with alkylating agents, they are so slight as not to offer any prospects of being able at present to direct the mutation process. Until more information is available from the experiments now in progress about the effect of radiation dose or chemical concentration on the spectrum of mutations in *Arabidopsis*, it is not possible to know whether to ascribe these differences to the mode of action of the mutagens or simply to the overall mutation-rate and preferential elimination of certain types of mutants. There is a high probability ($P < 0{\cdot}01$) that the spectrum of EMS-induced mutants varies with the concentration of chemical used.

Evidence put forward by Ehrenberg *et al.*[6] that the spectrum of chlorophyll mutations in barley is dependent on the mutagen fails to take into account adequately this dose factor. The low percentage of chlorophyll mutants which are 'albina' type after treatment with alkylating agents compared with radiation may be due to the fact, as may be deduced from their results, that this percentage always decreases with increased overall mutation-rate, perhaps due to preferential elimination of 'albina' mutants at high mutation-rates.

The results reported here show that in forward-mutation experiments, based on a broad spectrum, it is difficult to demonstrate differential response to mutagens, and that many factors must be taken into account. Previous claims for mutation specificity in higher plants must be regarded with caution as the results have been interpreted in ways which might not be agreed to by all statisticians.

This work was carried out under a Nuffield Foundation Grant.

AGRICULTURE

Use of Mechanical Barriers instead of Guard Rows in Field Experiments

A MAJOR disadvantage in manurial and other field experiments on trees and other perennial crops is the requirement for 'guard rows' between plots to restrict the roots of the experimental trees to the treated areas of soil. As a consequence, the plots are dispersed over a considerably larger area than would be required for the treatments alone.

A new technique, probably of wide application, is to use 'Vinyl' copolymer foil as a barrier to root extension across plot boundaries and to lateral movement of water from irrigated plots. This has been made possible by the development of a machine to lay the foil.

A special tine, fitted to a sub-soiler, encloses a pivoted laying leaf which feeds, horizontally, plastic foil 30 in. wide down into the soil so that it emerges as a continuous vertical strip within the channel formed by the tine (Fig. 1).

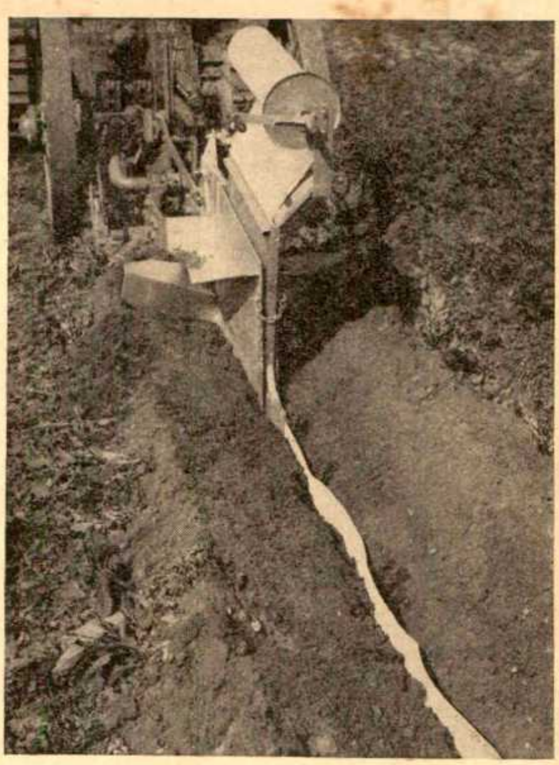

Fig. 1. Plastic foil being laid vertically in soil, to a depth of 34 in., to form a barrier to root extension across experimental plot boundaries

The technique has been developed in connexion with a large field experiment to determine the effects of different nitrogen and water régimes, and their interactions, on the growth and cropping of apple trees over many years. Vertical strips of foil 0·015 in. thick have been laid successfully down to a depth of about 34 in., delimiting the various plots on all four sides. The elimination of the need for guard trees has reduced the area required for the experiment from 11 to 4·7 acres.

The field method of laying the root barriers is to mark the boundaries of the plots with furrows and then to make all the runs in one direction before attempting the transverse ones. As the first runs are made, the laid foil is cut where the intersections will occur to enable the implement to pass through at right angles on the subsequent runs. Usually the gaps left at these intersections are not greater than 3 or 4 in. wide. Continuous laying is achieved by sticking the end of each new roll of foil to its predecessor with a double-sided transfer tape, using a little heat if necessary.

Normally a speed of about 0·75 m.p.h. has been maintained while laying at a mean draught of 12,100 lb. in a fine sandy loam soil passing into a clay loam over Kent ragstone, but occasional maxima of more than 20,000 lb. have occurred when the tine struck rock. In the course of four clear working days some 2·75 miles of foil were laid for a material cost of £900, which compares favourably with the £1,700 which would have been the cost of the 500 cu. yd. of concrete required to make equivalent barriers in the soil.

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned

Assistant Lecturer in Organic Chemistry—The Registrar, The University, Manchester 13 (August 1)

Research Assistant in the Department of Psychology—The Registrar, The University, Sheffield 10 (August 1)

Lecturer (with a good honours degree in physics or electrical engineering, together with experience in the field of communications (rather than in electronics)) in Telecommunications—The Clerk to the Governors, Woolwich Polytechnic, London, S E 18 (August 3)

Tutorial Student (graduate or about to graduate) in Mechanical Engineering—The Registrar, King's College (University of London), Strand, London, W C 2 (August 3)

Lecturer in Physics—The Principal, Nottingham and District Technical College, Burton Street, Nottingham (August 4)

Lecturer or Assistant Lecturer in Mathematical Statistics—The Registrar, The University, Manchester 13 (August 4)

Assistant Lecturer (interested in physical organic or inorganic chemistry) in the Department of Chemistry—The Secretary, The University, Edinburgh (August 8)

Imperial Chemical Industries Research Fellow, to carry out original research in Chemistry, Physics, Engineering (including Chemical Engineering) Metallurgy, Pharmacology or related subjects—The Registrar, The University, Sheffield 10 (August 8)

Research Assistant (graduate in agricultural botany, botany, biochemistry or agricultural chemistry, with interests in plant physiology or anatomy) in the Department of Agricultural Botany, to undertake research on silica uptake and deposition by grasses—The Registrar, University College of North Wales, Bangor, North Wales (August 8)

Assistant in Zoology—The Secretary of University Court, The University, Glasgow (August 10)

Technician in the Department of Zoology, Victoria University of Wellington, New Zealand—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 (New Zealand and London, August 10)

Curator (with a university degree in geology) of Museum and Departmental Collections in the Department of Geology, to be responsible for cataloguing and curating the Departmental collections of rocks, minerals and fossils—The Secretary, The University, Edinburgh (August 11)

Lecturer in Mathematics—The Secretary, University of St Andrews, Queen's College, Dundee (August 11)

Lecturer in Physiology—The Secretary, The London Hospital Medical College (University of London), Turner Street, London, E 1 (August 11)

Lecturer (preferably with special interests in fluid dynamics or numerical analysis) in Applied Mathematics in St Salvator's College—The Secretary, The University, College Gate, St Andrews, Fife (August 11)

Lecturer (with special interests in igneous or metamorphic petrology) in the Department of Geology—The Secretary, The University, Edinburgh (August 11)

Lecturer in Computer Science—The Secretary, Birkbeck College (University of London), Malet Street, London, W C 1 (August 13)

Lecturer in the Department of Mathematical Physics, for duties which will include the teaching of mathematical physics and applied mathematics, to undergraduate level and assistance in the postgraduate and research activities of the Department, which are at present primarily concerned with the quantum theory of fields and nuclear theory—The Secretary, The University, Edinburgh (August 15)

Lecturer (with good qualifications and teaching experience in physics and/or chemistry, and preferably a higher degree in education) in Education—The Registrar, The University Keele, Staffs (August 18)

Temporary Assistant Lecturer in Psychology (for two years)—The Registrar, The University, Keele, Staffs (August 18)

Lecturer (with an interest in physical metallurgy) in Chemical Engineering at the University College of The West Indies—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W C 1 (August 20)

Lecturer or Assistant Lecturer (with a degree in veterinary medicine or physiology) in the Department of Physiology—The Secretary, Royal Veterinary College (University of London), Royal College Street, London, N W 1 (August 25)

Assistant Lecturer (with a good honours degree in physics and some postgraduate experience) in the Department of Natural Philosophy, to take part in the plasma physics research programme of the Department—The Secretary, Royal College of Science and Technology, Glasgow, C 1 (August 31)

Lecturer in Chemistry at Fourah Bay College, The University College of Sierra Leone—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W C 1 (August 31)

Professor of Chemistry at the University of Canterbury, Christchurch, New Zealand—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1, or The Registrar, University of Canterbury (August 31)

Research Fellow in Chemistry at the University College, Ibadan, Nigeria—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W C 1 (September 1)

University Assistant Lecturer (preferably with a knowledge of either East or Central Africa, or the Pacific area) in Social Anthropology—The Secretary of the Appointments Committee, Faculty of Archæology and Anthropology, The University Downing Street, Cambridge (September 1)

Chair of Soils, and Chair of Agriculture (Crop Production) in the University of the West Indies (Imperial College of Tropical Agriculture, Trinidad)—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (September 5)

Lecturer (preferably with experience in vertebrate zoology, insect ecology, or marine biology) in Zoology at the University of Auckland, New Zealand—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 (New Zealand and London, September 7)

Reader in Mathematics at Royal Holloway College—The Academic Registrar, University of London, Senate House, London, W C 1 (September 10)

Lecturer in the Department of Chemical Engineering—The Secretary, University College, Gower Street, London, W C 1 (September 17)

Reader (with special interests in mineralogy and petrology) in Geology at King's College—The Academic Registrar, University of London, Senate House, London, W C 1 (September 20)

Reader in Mathematics at Royal Holloway College—The Academic Registrar, University of London, Senate House, London, W C 1 (September 20)

Chair of Forestry and Natural Resources—The Secretary, The University, Edinburgh (September 30)

Lecturer in Forest Inventory at the University of Melbourne, Australia—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1, or The Reader-in-Charge of Forestry, University of Melbourne (Australia and London, September 30)

Entomologist, Grade A/B (with a good honours degree in entomology (zoology) and a particular interest in biological control work)—The Director, Commonwealth Institute of Biological Control, Gordon Street, Curepe, Trinidad, W I (October 15)

Lecturer (graduate in chemistry and preferably with experience in the food industry), for duties which will include the teaching of chemistry and food quality control—The Principal, National College of Food Technology, St George's Avenue, Weybridge, Surrey

Lecturer (honours graduate) in the Department of Mechanical Engineering—The Registrar, The University, Liverpool, quoting Ref CV/142

Neurochemistry Research Fellow (honours graduate in biochemistry or chemistry), for biochemical investigations on muscle disease in the Neurochemical Research Laboratory of the Regional Neurological Centre, Newcastle upon Tyne—The Secretary, Newcastle General Hospital, Westgate Road, Newcastle upon Tyne 4

Research Assistant (with a degree or H N C in electrical engineering or applied physics, or an equivalent qualification and experience in electronics) in the Radio Astronomy Research Group—The Secretary, Department of Physics, Cavendish Laboratory, Free School Lane, Cambridge

Research Fellow (with at least three years postgraduate research experience) in the Department of Electron Physics, to lead a small group either in work related to the Space Research Programme or to associated laboratory ionic physics problems—The Deputy Registrar, The University, Edgbaston, Birmingham 15

Scientific Officer or Senior Scientific Officer (honours graduate, preferably with a Ph D in biochemistry, with interests in the isolation and chemistry of proteins, and in studies of enzymes) in the Physiology Department—The Secretary, National Institute for Research in Dairying (University of Reading), Shinfield, near Reading, quoting Ref 62/8

Senior Biology Master, to take charge of the Biology Department—The Headmaster, King's College, Taunton

SCIENTIFIC RESEARCH FOR INDUSTRY IN BRITAIN

A MAJOR theme of the report of the Council for Scientific and Industrial Research for the year 1961* is service for industry, and particularly the ways in which industry can be helped and encouraged to apply the results of scientific research Of two major questions on which indication of the Council's policy is awaited the report gives no guidance the report on aid for research and training in universities and colleges promised last year is still in the press, and the problems of providing large-scale equipment for universities and other institutions and of centralization of research facilities are no more than mentioned However, the report is almost enthusiastic about the possibilities opened up by Prof M Stacey's work at the University of Birmingham on the synthesis and properties of organic fluorine compounds—studies which could profoundly influence polymer, dyestuffs and biological chemistry Apart from reporting the progress of a scheme for demonstrating how research results can be applied in industry to improve efficiency and increase productivity, there is no indication of what is contemplated with regard to the research associations, beyond greater flexibility and the acceptance of a recommendation from the Industrial Grants Committee that further grants 'earmarked' for special activities should be offered These would be aimed at increasing the efforts of research associations in fields judged to be of particular importance, industrial health and safety being instanced

Under the special assistance scheme just mentioned, expenditure during the year was some £88,000, making a total of £264,000 on projects from twenty associations since the scheme was started Most of the scheme involved the extension of information services, and in general there has been a good response from industry to the introduction of the additional services Clearly this aspect of the work of the research associations which is related to their educational functions is of growing importance However, the Robbins Committee may well have some valuable comments here in due course, of which full account should be taken of any modifications in the structure or functions of the research association system which may result from the inquiry the Council has already instituted

The Industrial Grants Committee also supervises, through a sub-committee, the work of the Industrial Operations Unit, which seeks to show in practical terms how the systematic study of operational methods can lead to greater efficiency without any basic change in technology An example of the Unit's work during the past year is seen in the special course in simplification of work presented for the British Steel Castings Research Association. Other research associations are showing increasing interest in the application of mathematical methods to the making of decisions These activities, which originally were financed from Conditional Aid Funds, are part of the Department's policy of securing rapid dissemination and application of the results of research

They are also linked with the information activities of Headquarters which the Council has carefully reviewed over the past three years Little more information, however, is forthcoming in the present report on this aspect of the Department's work, although the Council set up in 1959 a Committee on the Dissemination of Scientific and Technical Information, with as a first main task the consideration of the regional organization of technical information services While the Department's branch offices in Scotland and Wales have been strengthened and grant-aid for a further three years is being given to six regional technical information centres in Birmingham, Bristol, Liverpool, Manchester, Newcastle and Portsmouth, there is no discussion of the implications of the proposals in the Roberts Report on the public library service, and no indication that the new centres have been planned with any regard to the potentialities of the public library service or to existing university or technical college libraries

No co-ordination of public information services can be expected to avoid waste of effort or finance if due regard is not paid to such potentialities, the reluctance of the Council to provide sufficient information for an informed judgment to be made on this aspect of the Department's work is somewhat puzzling On the other hand, the Department is giving increasing attention to its publications and is seeking to make its publications more effective and attractive Besides improving lay-out and typography, publications specially designed for industry have been launched One series, for example, puts the results of selected studies in the human sciences into a concise form suitable for use by industrial management Another features various technical developments, often stemming from the work of the research stations and research associations, and sometimes providing concise surveys of particular fields of technology Besides this, the Information Committee is now considering specifically the improvement of documentation techniques and what further action the Department can usefully take in this field

The Council's report directs particular attention, however, to two relatively new types of activity which also bear on this general problem of assisting industry to utilize the results of research First, it emphasizes the value of the series of detailed studies of particular industries which the Economics Committee has been making in recent years The formation during the year of the new British Ship Research Association, which will take over the facilities of the former Parsons and Marine Engineering Turbine

---

* Department of Scientific and Industrial Research Report of the Research Council for the year 1961 Pp 60 (Cmnd 1734) (London H M Stationery Office, 1962) 4s net

Research and Development Association and undertake a more extensive research programme is a direct result of the Economics Committee's recommendations in its report on *Research and Development Requirements of the Shipbuilding and Marine Engineering Industries* A new organization, continuing the name "Pametrade", will take over design work for marine turbine manufacturers and the Council is considering proposals for strengthening the national effort in research and development in marine engineering The Economics Committee, in conjunction with the Board of Trade, is making a similar study of requirements for research and development in textile machinery It has completed investigations concerning research and development in foundry engineering and equipment, a study of research and development relating to other metal-forming processes is also contemplated

The second matter is the placing of development contracts in industry Support has already been given for the development of a large gear-grinding machine incorporating entirely novel mechanical principles and embodying some of the latest techniques developed at the National Engineering Laboratory. A second project in the machine-tool field is under consideration, and a project designed to increase the overall effort on research and development in computers and to improve co-ordination of work in this field in industry and Government laboratories is being discussed with the firms concerned This project will cover, in the first place, research and development on new ranges of components and techniques for the next generation of digital computers, later, it will include the study of problems arising in the design of computers using such components

The industrial recipients of development contracts will contribute substantially to the cost, and normally a return will be sought on the Government contribution, usually by means of a levy on subsequent commercial sales Other projects which may warrant support are being examined and close liaison with the National Research Development Corporation is being maintained The Minister for Science has repeatedly expressed the view that more use should be made of development contracts, and the system has attracted noticeable support when questions of research and development have been debated in Parliament in recent sessions The position of the National Research Development Corporation was specifically mentioned recently by Lord Hailsham in referring to the Treasury Committee now examining the Government organization for civil research It is possible that the relations of the Corporation with the Department as well as with the Board of Trade are receiving fresh and independent scrutiny

The Council expresses the hope, in conclusion, that by economic studies of research requirements, by the award of development contracts, by the continued support of research associations, and by the work done in its own research establishments, the Department makes a significant contribution to increased industrial efficiency and, therefore, higher productivity On the evidence of this report, subject to all the reservations already made, that hope seems to be justified On certain subjects the interest at the moment appears to have shifted outside the Council's own responsibility the Minister for Science would seem to be looking to the Trend Committee for guidance on some matters of organization and responsibility, though it is curious that the Council for Scientific and Industrial Research in this report makes no reference to the findings of the Zuckerman Committee on the management of research Again, it may be that the Minister is looking to the Advisory Council on Scientific Policy for guidance when his inquiry into the functions of the research associations is complete Certainly that body is better placed for consideration of the general co-ordination of information activities and the extent to which the Council of Scientific and Industrial Research, or other Research Councils, should follow the lead of the National Science Foundation and enter into the study of documentation problems Meanwhile, however, the Council could well expedite its own account of its activities in support of university research and training, for even if such activities have only an indirect effect on industrial efficiency, that effect is vital, and the Department's contribution to the supply of Britain's trained manpower and its most effective use is of increasing rather than diminishing importance

NEWTON'S CORRESPONDENCE, 1688–1694

The Correspondence of Isaac Newton
Vol 3 1688–1694 Edited by Prof H. W. Turnbull, F R S Pp xviii + 445 + 6 plates (Cambridge At the University Press Published for the Royal Society, 1961) 147*s*. net

THE review of this third volume of *The Correspondence of Isaac Newton* must open on a melancholy note Its preface is still written by Prof H W Turnbull, but a note tells us that he died before the volume was published, and the preface itself ends with a paragraph recalling the sudden death in 1960 of Mr W H Robinson, who had seconded him in the preparation of the first three volumes In starting the great undertaking with such devoted care and brilliant scholarship, they have earned the gratitude of many generations of historians of science We may be sure that the continuation of the work, in the hands of Dr J F Scott, will fully uphold the high standard of excellence set by the initial volumes

In its outlay the present volume follows the same pattern as those preceding it A new feature is a list of errata and addenda to the latter, which in particular contains important corrections to the notes on chemical matters Even so, that these errata do not fill more than three pages is a striking testimony to the quality of the editorial commentary, a quality which is as high as ever in the volume under review, in spite of the greater variety of the topics occurring in it

In fact, there is a noticeable change in the general character of the correspondence of this period, which corresponds to an actual change in Newton's preoccupations after the publication of the *Principia* One may say that this publication marks the end of his scientific creative period, certainly he remained active in science until his last days, but the work he did —mainly centred around the preparation of two further editions of the *Principia* and the publication of several editions of the *Opticks*—was no more than an elaboration of his early ideas Moreover, his active participation in politics, and afterwards his anxiety to obtain some administrative office, show his determination to abandon his studious college life However, it would be wrong to think that the later correspondence would not have the same interest for the study of Newton's scientific work as that contained in the two first volumes For Newton is so reticent in his writings, especially about his more general conceptions, that a full understanding of his thought cannot be gained from his books and published papers alone no scrap of evidence in this respect may be neglected, however indirect it may seem, and since to the last Newton's meditations did not cease to concentrate on the same basic ideas, late documents are just as precious as early ones in helping to elucidate these ideas Thus, this third volume, which covers the six years following the appearance of the *Principia*, is just as packed with material of scientific importance as those preceding it Besides, it contains, in greater amount than the latter, documents illustrating Newton's personality and his wide interests in human affairs

Much of this documentation is published here for the first time, some had been published before, but only in comparatively inaccessible places and often in imperfect form and even the pieces well known since Brewster's time acquire an enhanced value by appearing in such a complete, chronologically arranged collection of authentic texts Of special importance for the history of Newton's mathematical and astronomical investigations are the memoranda drawn up by David Gregory after conversations he had with Newton We must be grateful for the editor's decision to include them, and yet regret that he left out a most interesting manuscript (mentioned in note 10, p 339) given by Newton to Gregory, of which only extracts are available in print, these fragments, containing early drafts of some parts of the famous *Scholium generale* which concludes the later editions of the *Principia*, are remarkably revealing for the evolution of Newton's philosophical outlook, and an authentic reproduction of the whole document is highly desirable About this vexed question of including pieces which are not strictly letters, the editor apparently had second thoughts, he has inserted in the present volume three early documents of the greatest historical importance, the regular place of which would have been in the first volume Such inclusions, even belated, can only be encouraged, however, later insertions ought not to be made at arbitrary places (as in the present instance of Nos 347, 348, 349) but preferably at the end of the volumes, otherwise, their location is likely to cause much inconvenience

The impression made by the appearance of the *Principia* is well illustrated in this volume, in which we can study the reactions not only of specialists like Huygens, Leibniz or Gregory but also of cultivated laymen such as Locke and Bentley Of particular value in this respect is the correspondence of Fatio de Duillier with Huygens, Leibniz and Newton (the latter hitherto unknown), Fatio was an enterprising young man (he was born at Basle in 1664) studying at first hand the new discoveries in mathematics and astronomy—a thrilling experience, which may be visualized by those of us who made their first steps in physics in the twenties He must have been of a particularly engaging disposition, for he is treated by the three great men who knew him with more than usual kindness and esteem The letters exchanged between him and Newton reveal to us an unexpected, and rather pathetic, fatherly attitude of the latter towards the candid youth who trusted him and showed intelligent interest in his ideas

Among the many points of interest in the correspondence relating to the *Principia* I shall especially mention the surprising error committed by Newton in the 37th proposition of the second book, in which he asserts that the velocity of flow of a liquid from a hole at the bottom of a vessel is the same as that acquired by a body falling freely from rest through a height equal to *half* that of the liquid in the vessel Although Huygens immediately saw (see No 344) the contradiction between this result and the law of conservation of energy (which he had recognized as the main principle of mechanics), we learn (note 3 to No 371) that Fatio de Duillier, who likewise discovered the error, could only dissuade Newton from his opinion by performing experiments to the purpose No more convincing proof could be found of how foreign ideas of conservation were to Newton's conception of force, in contrast to the Continental tradition of Stevin, Huygens and Bernoulli

Of great moment also are the well-known tract *De natura acidorum* (No 387), in which Newton develops striking considerations about the constitution of matter, and the correspondence with Bentley concerning the teleological interpretation of the peculiarities of the solar system in support of the existence of a divine providence It is not easy for the modern reader to pass fair judgment over what must appear to him a rather naive way of appealing to finalistic arguments, in this respect it is instructive to observe, however, that even such a bold and comparatively unprejudiced thinker as Huygens was moved to adopt a deistic opinion by the consideration of the apparently teleological organization of life In any case, the evidence we have over Newton's own philosophical thinking, scanty as it is, compellingly suggests that the conciliation of his belief in a personal God with the exigencies of the rationalistic conception of natural philosophy was not reached without a mental struggle of really tragic proportions It can scarcely be doubted, in particular, that his virtual retreat from scientific pursuits, and the steps he took to seek a public office, precisely at the time when he had apparently won his greatest triumph in science, is at least partly motivated by a sense of dissatisfaction, or even frustration, at his inability to achieve harmony in a comprehensive view of the universe That he in those years underwent great mental strain is shown by the temporary breakdown he suffered in September 1693, evidence of which appears in two letters to Pepys and Locke (Nos 420, 421), which have given rise, both at the time and later to much rumour and unfounded speculation

Although the real cause must lie deeper, it appears that Newton's breakdown was prompted by his disappointment in not being able to secure a position which would have allowed him to escape from the seclusion of his college In 1688 he had been elected, together with Sir Robert Sawyer, to represent the University of Cambridge in the Parliament assembled on the accession of William and Mary Of his not very conspicuous activity in this function the main testimony is a correspondence, duly reprinted in this volume, with John Covel, the vice-chancellor, about the confirmation of the statutes of the University, some other minor information on Newton s election may be found in the study by M B Rex, *University Representation in England 1604–1690* (Allen and Unwin, 1954) He was not re-elected in 1690 and his endeavours in the ensuing years to obtain a suitable office did not go without humiliations which—one gathers from hints in the correspondence (see Nos 377, 384, 420, 423)—he seems to have acutely resented

Newton's interest in public affairs cannot be separated from his earnest and deep-going studies of ancient history and especially of the early history of Christianity, in which he sought the foundation of political law and order in the same spirit as he tried to derive from the analysis of natural phenomena the law and order which God had designed for his creation In this volume we are given the first correct text of one of his most considerable works in this field, together with two previously unpublished additions to it (Nos 358, 359, 360), and are thus enabled to form an opinion of the true character and value of this little-known and often misunderstood aspect of his thought After reading the long "historical account of two notable corruptions of Scripture, in a letter to a Friend", I do not hesitate to put this pamphlet on a par with the *Provinciales* Certainly, there is nothing in it of the fiery Frenchman's passionate eloquence and biting sarcasm, but the same merciless exposure of fraud and delusion is here as effectively achieved by restrained statement and cool logic This does not mean that Newton's composition is artless he knew how to use rhetorical devices, and it requires great skill to display such erudition without becoming tedious, to develop intricate arguments with such unfaltering clarity and to formulate conclusions with such forceful concision But the greatest beauty of the epistle lies in its candour One sentence in it might be the motto of every scientist "There cannot be better service done to the truth than to purge it of things spurious" L ROSENFELD

PROBABILITY AND INDUCTION

Theory of Probability

By Prof Harold Jeffreys Third edition (The International Series of Monographs on Physics) Pp viii+447 (Oxford Clarendon Press, London Oxford University Press, 1961) 84*s* net

THE appearance of a third edition of this book is an indication of its permanent place in the literature on probability Its avowed object, quoted from the preface to the first edition, "is to provide a method of drawing inference from observational data that will be self-consistent and can also be used in practice" It is thus essentially a book on the use of probability in induction A substantial part of the book is occupied with discussions of statistical testing and estimation procedures, although recent developments in the analysis of time series and other stochastic processes are not seriously considered, so that the discussion of statistical procedures should presumably be regarded as illustrative primarily of the author's approach

In this new edition one or two additions and rearrangements of material have been made; for example, there is some amplification of the discussion of the problem of finding self-consistent rules for assigning values to prior probabilities Such rules, while they tend to make the theory more epistemological and conventional in character, in contrast to inverse probability procedures based on personal prior probability assessments, help to make this work one of the most impressive attempts so far to formulate an explicit induction procedure founded on probability However, I am far from alone in thinking that the procedure still has serious disadvantages as well as advantages, so that the optimum degree of formalization of the induction problem remains a matter for legitimate debate The formal method of assigning prior probabilities to theories and hypotheses not only involves the task of numerical assessment of these probabilities but also first an enumeration of all the hypotheses and an acceptance that one of them is true (compare Einstein's remark that every scientific proposition, being man-made, is false)

Probability can alternatively be studied as a purely mathematical subject, or in relation to observed statistical regularities Statisticians are largely concerned with the use of probability in this last sense, it is important to recognize this, and not slur over it, as advocates of inverse probability have a tendency to do The author's thesis is not helped by such remarks as (in the new preface) "Adherents of frequency definitions of probability have naturally objected to the whole system But they carefully avoid mentioning my criticisms of frequency definitions, which any competent mathematician can see to be unanswerable" This remark is provocative and misleading It ignores the dependence of modern probability theory, as formulated, for example by A N Kolmogorov, on frequency (cf *Foundations of the Theory of Probability*, English translation, p 3 New York, 1950) Jeffreys, in fact, makes no reference to Kolmogorov, and is also in other ways curiously uneven and cryptic in his references to relevant literature Writers such as R B Braithwaite and R F Harrod, who scarcely see eye to eye with Jeffreys, are not listed in the index Even L J Savage and I J Good authors of books advocating inverse probability methods, but with the use of prior probabilities more personal than those of Jeffreys, get no mention One feels that writers on induction have a particular obligation to appraise other points of view fairly and comprehensively, as part of the evidence before them on the merits and demerits of their own case M S BARTLETT

HISTORICAL AND PSYCHOLOGICAL ORIGINS OF SCIENCE

The Origins of Science

An Inquiry into the Foundations of Western Thought
By Ernest H. Hutten Pp. 241. (London George Allen and Unwin, Ltd , 1962) 28*s* net

"THE aim of this book is to explain science from its historical and psychological origins " The drive behind Dr Hutten's enterprise is dissatisfaction with the alleged failure of philosophers to re-fashion the categories of criticism within which the Greeks, through their relative ignorance of science, were compelled to work, his cure for this is to recognize a much less sharp boundary between inner and outer experience, reason and emotion, than has traditionally been the custom, his method, the reinterpretation of concepts in the light of depth-psychology. Thus, scientists may be shocked to learn that the line between a paranoid system and a scientific theory is perhaps very narrow (p 189), similarly natural philosophers, that Thales unconsciously took as the prime stuff the milk in the mother's breast; and mathematical logicians, that the same object served positively as the generator of the idea of the mathematical continuum and negatively as that of the principle of contradiction. To the majority of scientists these notions might be taken as a timely warning to 'keep off' this book, but to do so would, in my opinion, be a grave mistake. For not only has Dr Hutten started many speculative hares well worth chasing, despite the sometimes fantastical country through which they run, but also the relevance of his general thesis and the cogency of his reasoning are largely independent of the adequacy or 'truth' of the sexual objects that from time to time, and almost incidentally, he points to as the prime movers. Once this is accepted, the book can be—must be—read right through with growing appreciation of the importance of the author's message that if, as he believes, the scientific method is the safeguard for the criterion of truth and reality, it can be stripped of its concomitant perils only by being reinterpreted in terms of its human origins in which infantile fantasies play a not inconsiderable part. Moreover, it is in the later pages that the author's former concern with the *Language of Physics* enables him to demonstrate that his thesis rests on no merely transitory psychological fashions.

The exacting reader must, however, be prepared to be charitable in regard to Dr Hutten's loose use of prestige-words like 'the Renaissance' and derogatory words like 'metaphysics'—it is not clear, for example, that an Earth-centred cosmos is necessarily more 'metaphysical' than a breast-centred one ! The book is at times tendentious, often repetitive, sometimes exasperating; to the accusation that it is lacking in order Dr. Hutten would reply that 'a little chaos is always needed for creation'. But whatever its faults, it is never dull, which is more than can be said of many specimens of more 'scientific' writing.

W P. D WIGHTMAN

RADIATION PHYSICS AND HEALTH

Radiation and Health

By Dr Katharine Williams, Dr C L Smith and Dr H D Chalke. Pp ix+206+7 plates (London Longmans, Green and Co , Ltd , 1962) 28*s* net

THIS book was written primarily for medical readers, having its origin in a symposium of medical officers of health, held in 1958. It is rather more than an edited version of the proceedings, but has still inherited some of the common defects of such a publication, particularly in that there is a certain lack of continuity and some repetition, though the editors admit the latter and believe that it may help to emphasize some of the more important points.

The editors have, between them, contributed only three of the eleven chapters, but are backed-up by a good team, some of whom are international authorities in their fields.

Dr Burch and Mr Burns have written very good reviews of their subjects, dose-rates from natural background and radioactive waste disposal. Dr Rundo has covered the difficult problem of biological monitoring in a very able manner, though his mathematical arguments could well have been omitted for this audience, medical officers are generally the first to admit their own limitations in this direction. Dr Williams has written a general survey of public health problems and Dr Chalke has contributed a chapter on legislation and education, the latter is somewhat of a catalogue, but is a useful summary of relevant Acts. In the main, Mr Haybittle's chapter on measuring and monitoring radiation provides a good background, though his statement that photomultiplier dynodes are usually made of beryllium–copper alloy is open to criticism, this material can be used, but antimony–cæsium is nowadays much more commonly used for secondary-emitting surfaces.

Four appendixes cover maximum permissible levels of radiation, maximum permissible concentrations of some radionuclides in air and water, precautions to be taken when working with radioactive materials, and simple first-aid action to be taken in accidents involving radioactive contamination. Of these, only the first is really required in a book of this type. The second is simply a long list of information, which is virtually useless to any but the specialist and incidentally uses an out-of-date grading of radioisotopes in terms of radiotoxicity, it would have been much better to have given references to the appropriate publications. The material contained in the third and fourth appendixes is certainly useful to the user of radioactive materials, but could have been better presented in a chapter devoted to safe methods of handling radioisotopes, an expansion, perhaps, of Mr Dunster's contribution on the use and occupational hazards of radiation, which is rather on the brief side.

While the health physicist will find less to interest him than the title and the authors' names suggest, the book will certainly appeal to many scientists and doctors who wish to learn some of the background, and it should also be comprehensible to the interested layman.

HUGH D EVANS

PROGRESS IN SPACE SCIENCE

Space Research II

Proceedings of the Second International Space Science Symposium, Florence, April 10–14, 1961. Edited by H C van de Hulst, C de Jager and A F Moore. (Organized by the Committee on Space Research—COSPAR, and Consiglio Nazionale delle Ricerche.) Pp xv+1241 (Amsterdam North-Holland Publishing Company, New York Interscience Publishers, Inc , 1961) 200*s*

THIS massive book is a record of the papers presented at the second International Space Science Symposium at Florence in April 1961. During recent years, especially in new and rapidly expanding subjects, like space science, delays in publication have formed a major obstacle to scientific advance, and have been especially serious to workers remote from the main centres of activity. It is therefore very gratifying that this book was published in 1961, within eight months of the conference. The North-Holland Publishing Co , together with Prof Van de Hulst and his co-editors, are to be congratulated on this quick publication, which is all the more creditable because the book runs to more than 1,200 pages, includes abstracts in Russian of every paper, and is handsomely produced, with few errors or misprints. Furthermore, the papers have been edited in an admirably uniform fashion: for example, all the references are numbered and the clumsy names-and-year system is avoided, though no doubt many of the authors originally used the latter method.

The Florence Symposium was limited to certain special topics in space research, which were specified in advance, with the aim of keeping the number of papers within reasonable limits. In practice, however, most potential authors managed to convince themselves that their papers came under one of the specified headings, so almost all aspects of space research are covered. The coverage is, however, not balanced, and prospective purchasers should be warned that there is little about biology and not much about deep-space topics—the Sun, the Moon and the Planets, and the interplanetary medium.

The 105 papers which compose the book are divided into nine parts. Part 1 is on optical tracking, and the 17 papers include reports on experience in optical tracking in the U.S.S.R. by A. G. Massevitch and in the United States by G. Veis and F. L. Whipple. Part 2 contains ten papers on radio tracking. Part 3 is entitled "Dynamics of Satellite Motion", but also includes the first papers on determining the ellipticity of the Earth's equator from satellite orbits, by I. G. Izsak and W. M. Kaula. Part 4 consists of 7 papers on telemetry and data recovery. Part 5 is entitled "Recent Results from Instrumented Satellites and Spacecraft": the 13 papers include two by K. I. Gringauz on the charged particles in the upper ionosphere and at great distances from the Earth, largely derived from measurements by *Luniks* 1–3. Part 6 (five papers) deals with the World Magnetic Survey. Part 7 is entitled "Special Events", and refers primarily to unusual outbursts of solar activity and their consequences (although a special event of a different kind took place while this session was in progress—the orbital flight of Major Gagarin). Most of the 17 papers in this section are concerned with the solar flares of November 1960, and they include L. G. Jacchia's elegant analysis of the large changes in upper-air density during these events. Part 8, with 11 papers, has the title "Reference Atmosphere", and provides the scientific background for the International Reference Atmosphere of the Committee on Space Research (CIRA 1961), which was published later in 1961. Finally, in Part 9, there are 18 papers on research by means of sounding rockets.

Although the book costs £10, it cannot be called unduly expensive and is certainly more rewarding than any space-research experiment which could be conducted at a similar cost. Every library with any pretensions to cover space research should acquire the book.

D. G. King-Hele

CURRENT CANCER TOPICS

Advances in Cancer Research

Vol. 6. Edited by Prof. Alexander Haddow and Sidney Weinhouse. Pp. ix+524. (New York: Academic Press, Inc.; London: Academic Press, Inc., London, Ltd., 1961.) 86*s*.

THIS publication has the same high standard of writing and production as the first five volumes of the series edited by Dr. J. P. Greenstein and Prof. A. Haddow. The series began in 1953, and, except for 1957, volumes appeared annually until 1958. In 1959, Dr. Greenstein died. Now, after a lapse of three years, the latest volume has appeared with Dr. S. Weinhouse as co-editor.

There are eight interesting topical chapters in the present volume. Bodansky discusses changes which occur in enzymes of serum and blood elements in the presence of neoplasia. He notes the unique position of the leukæmic leucocyte for studies of changes in a readily available cancer cell uncontaminated with connective tissue. He also points to the possible use of studies of isozymes or enzyme variants in the detection of specific disease processes in particular tissues. Braun and Wood present a short review chapter on problems relating to the origin and metabolism of plant tumours. This topic has received scant attention in journals dealing with cancer research. Nevertheless, it is pointed out that at the cellular level there are no fundamental differences between the plant and animal kingdoms. The authors end on the hopeful note that malignant tumour cells in general may not be irreversibly altered cells and that it may be possible to bring about the return of such cells to normality.

In systemic therapy with drugs, such as HN2, severe toxic effects may be encountered. In order to minimize these effects, techniques have been evolved for the isolation of tumour areas from the rest of the circulation and for their perfusion with anti-cancer drugs. These interesting new methods are described by Creech and Krementz and the results of treatment of 242 cancer patients are given. Gross deals with the viral ætiology of mouse leukæmias and in a subsequent review chapter Miller discusses factors other than viruses which also elicit murine leukæmia. The interesting finding that thymectomy reduces the susceptibility of mice to virus leukæmia is discussed.

The topic of radiation chimeras is examined by Koller, Davies and Doak. Animals may sometimes be protected from the serious effects of X-irradiation by transplantation of spleen or bone marrow of their own or of some other species. Possible applications in the treatment of human leukæmia and of radiation accidents are described. Timmis discusses the anti-tumour action of purine, pyrimidine and folic acid antagonists and directs attention to a possible relationship between the mode of action of alkylating agents and the purine antimetabolites.

In the last chapter, Weber describes the behaviour of liver enzymes and metabolites during hepatocarcinogenesis. He presents a useful comparison of the rapidly growing Novikoff transplantable hepatoma with the slow-growing Morris hepatoma No. 5123 which is at present receiving a good deal of attention. Among other things, it is noted that these transplantable hepatomas resemble each other in that they fail to respond to injections of substrates which are able to bring about marked enzyme induction in normal liver tissue. Finally, with regard to the difficult question of the essentiality or otherwise of a particular biochemical lesion for neoplasia, Weber notes that this might be assessed by determining whether the re-establishment of a corresponding normal tissue-level leads to inhibition of tumour growth.

The present volume is a valuable stimulating contribution to the literature of cancer research and it is to be hoped that *Advances* will continue to appear regularly in future.

W. J. P. Neish

Proceedings of the Symposium on Algology

Edited by D Raghavan and P Kachroo. (Organized jointly by the Indian Council of Agricultural Research and Unesco South Asia Science Co-operation Office, New Delhi, December, 1959) Pp viii+406 (New Delhi Indian Council of Agricultural Research) n p

THE importance of algae as actual or potential parts of the food supply for the vast populations of Asia (and elsewhere) and as a source of industrial or agricultural products is now well known This symposium was organized to discuss present knowledge and stimulate further work, the latter aspect being the subject of a series of recommendations made by an international committee About thirty papers were given Prof M O P Iyengar, the doyen of Indian phycologists, described several new or interesting green algae in one of the two 'popular' lectures In the other Prof I Tamiya, who has done so much to further the controlled mass culture of algae, reviewed the present use of algae as food and the problems which must be solved before the agricultural or industrial utilization of forms such as *Chlorella* is an economic proposition The quality of the other published papers is rather variable There are accounts of original research work, valuable assessments of present knowledge, accounts of subjects previously reviewed elsewhere and curiosities such as the alleged activation of photosynthesis by sound waves from an electric bell Nevertheless, even if a few parts of the published accounts are not very interesting, the meeting together of so many phycologists to report and discuss matters of mutual interest will have been of great value This symposium is a further welcome example of the practical interest in algae shown by the Indian Council of Agricultural Research J W G Lund

Essay on Atomism

From Democritus to 1960 By Lancelot Law Whyte Pp vii+108 (Edinburgh and London Thomas Nelson and Sons, Ltd , 1961) 16*s*

MR WHYTE clearly regards the present state of thought in fundamental physics as an uneasy stage of lull before the storm His essay is an attempt to analyse the history of atomism for clues to the next series of developments The search does not, of course, result in any new theories nor does it present any startling new evidence It does, however, present existing evidence in a digestible form

The average scientist would associate the origin of the atomic concept of matter with Democritus, but is uneasily aware of a discontinuity in the story before it begins again with Dalton The chronological table and commentary, which occupy nearly half this volume, conveniently plug this gap in our knowledge and also summarize the story after A D 1800 The increasing density of entries in the post-1945 section naturally reflects both the increasing effort in physics and also the impossibility of picking out the really important developments immediately they occur

In his analysis the author reasonably suggests that further major progress will probably involve the re-examination of some tenaciously held article of faith as with the case of parity conservation This is, of course, nothing more than anyone with a broad awareness of the history of science will already have concluded However, Mr Whyte does indicate also what he considers to be the specific points of weakness in present theory and even the requirements of an 'ideal atomic theory' Few would probably agree with him in detail, but his thoughts should serve as a useful basis for fireside discussions among amateur fundamental theorists The book is firmly recommended for this purpose though scarcely to the complete layman J W Leech

Nuclear Energy Simplified

By John Ernest Radford Pp ix+141 (London Macdonald and Co (Publishers), Ltd , 1961) 28*s* net

THIS book is another attempt to make nuclear power and associated topics intelligible to the general reader It does so by simple descriptions and diagrams, avoiding the use of mathematics

The first half of the book outlines the development of the atom, nuclear fission and radioactivity The material is quite well presented but the style lacks clarity and some sections are difficult to follow In particular, the part dealing with the applications of radioisotopes is done in a perfunctory manner and suffers from loose phraseology (for example, p 53, "radiation of low energy intensity") A description of several nuclear reactors and their fuels is followed by a chapter on the design and operation of Calder Hall Possible future developments in the field of nuclear energy are explored, and here the section on thermonuclear processes suffers in that reference is made almost solely to *Zeta*, other machines being ignored The final chapter discusses health hazards from radiations, but unfortunately is misleading and out of date

The overall impression is that too many topics (from atomic structure to waste disposal) have been included in the book with a resulting loss of coherence Basically, however, the book is sound and could be useful background reading for anyone with a little knowledge in this field It is well produced with clear diagrams, a good index and few errors

Nuclear Reactor Instrumentation

By M W Jervis (Nuclear Engineering Monographs, No 13) Pp vii+74 (London Temple Press, 1961) 12*s* 6*d* net

"NUCLEAR Engineering Monographs" are intended to give readers a broad outline of particular subjects in return for a modest outlay This latest book in the series certainly achieves this objective with considerable success, the author having covered a great deal of ground in a compact and readable volume The scope is not as wide as the title suggests, the accent being almost entirely on reactors of the gas-cooled graphite-moderated type with only occasional references to other reactor systems

In writing a treatise occupying only 74 pages a major difficulty is to decide what to omit Thus, while the choice of material included is generally good, some of the subject-matter is inadequately presented In the introduction, for example, the simplified treatment of reactor kinetics could have included with advantage the effects of delayed neutrons, the case for wide-range neutron flux instrumentation could have been made more convincingly

Despite these shortcomings, which are ameliorated by the provision of an ample bibliography, the book outlines principles and discusses the construction and application of those instruments which are peculiar to nuclear reactor control and to the safety of plant and personnel The author has justifiably avoided instrumentation commonly encountered in other engineering fields Ian Wilson

INTERNATIONAL CO-OPERATION IN SPACE RESEARCH (I)*

By EDWARD R DYER, jun
National Academy of Sciences, Washington

THE Committee for Space Research (COSPAR) of the International Council of Scientific Unions (ICSU) held its fifth plenary meeting and associated sessions of its Working Groups in Washington, D C, during April 30–May 9 Five days were given over to the Third Annual International Space Science Symposium In addition to this Symposium, COSPAR acted as co-sponsor of two other special three-day Symposia held in Washington during the week before, these were the International Symposium on Rocket and Satellite Meteorology (with the International Association of Geomagnetism and Aeronomy and the World Meteorological Organization) and the International Symposium on the Use of Artificial Satellites for Geodesy (with the International Association of Geodesy of the IUGG) The host organization was the Space Science Board of the U S National Academy of Sciences, headquarters for the meetings and the Space Science Symposium were in the Academy building, but some of the larger meetings were held in the auditorium of the New State Department Building nearby

Prof Maurice Roy, professor of mechanics at the École Polytechnique (Paris), was elected president of COSPAR to serve the remaining year of the term of office of Prof H C van de Hulst of the University of Leyden Other items of business transacted during the working sessions were

(1) The laying of plans for a co-operative international programme for space research during the International Year of the Quiet Sun, which include plans for rocket measurements in the auroral zones and the polar caps (including the southern hemisphere), for a synoptic rocket study of high-altitude winds, with special emphasis on experiments during the days immediately following two chosen dates, and a study of the *D* and *E* regions of the ionosphere during the solar minimum

(2) Acknowledgment of the announcement by the United States of her intention to launch a geodetic satellite with a flashing light, and the encouragement of potential observers with suitable optical equipment to photograph it with the assistance of orbital predictions to be provided by the U S National Aeronautics and Space Administration (NASA)

(3) The adoption of revised and unified codes for the transmission and exchange of satellite orbital data and other measures designed to expedite this process

(4) The extension and clarification of agreements to exchange space research data through the medium of the World Data Centres, as set forth in a revised *Guide to Rocket and Satellite Data Exchange*

(5) The adoption of a number of steps designed to standardize nomenclature, terminology, measurements, etc

(6) Review of work during the past year on the COSPAR International Reference Atmosphere, and plans to extend work toward further refinement of the Reference Atmosphere under the chairmanship of Dr W Priester during the coming year

(7) The establishment of a six-man Consultative Group on Potentially Harmful Effects of Space Experiments, with the membership drawn from such diverse fields as astronomy, radiation physics, atmospheric physics and chemistry, communications, meteorite penetration, and microbiology This group was set up in response to a request from ICSU, and will serve as the nucleus of a body for investigating the possible undesirable consequences of certain space experiments for the environment or for scientific research, for which purpose it will call to its assistance specialists with competence in particular problems on an *ad hoc* basis

(8) Re-confirmation of its earlier offer to assist the United Nations Committee on the Peaceful Uses of Outer Space, especially in the supplying of information on technical questions or in the arrangement of conferences on scientific topics.

(9) Acceptance of invitation of the Academy of Sciences of Poland to meet in Warsaw in June 1963

During the meetings a number of excursions was arranged, namely, to Cape Canaveral, to the NASA rocket launching facility at Wallops Island, Virginia, and to the NASA Goddard Space Flight Center, where the new laboratories in which artificial satellites are being built and tested were open to the scientific visitors Social functions included a tea-reception by the National Academy of Sciences, an Academy dinner for officers and national delegates to COSPAR, a reception at the Department of State by the Hon Lyndon B Johnson, vice-president of the United States, and Mrs Johnson, and a reception at the Embassy of the U S S R

The programme for the opening general assembly on May 2 comprised, besides ceremonial speeches of welcome and greetings (including a message from President Kennedy delivered by his scientific adviser), the oral presentation of summary annual reports from the 18 countries adhering to COSPAR on their respective programmes in space science during the previous year and, in most instances, a note on plans for the immediate future As one might expect, the reports of the U S S R and the United States were considerably more extensive than the others, but it is most interesting to see how much can be, and is being, done by those nations without satellite programmes of their own These programmes follow several patterns the launching of high-altitude balloons and rockets for the investigation of cosmic rays, the upper atmosphere and ionosphere, the deduction of useful results from the motion of artificial satellites on the gravitational field of the Earth or on the density of the upper atmosphere and time variations thereof, the building and operation of tracking facilities, both optical and radio, and a considerable amount of theoretical, analytical, design, and developmental work The United Kingdom and the United States announced the launching of *Ariel*, a satellite carrying instruments designed and built by British scientists to measure various properties of the ionosphere and launched under a bilateral international agreement by the United States (see *Nature*, 194, 432, 1962) The Canadians described the topside ionosphere sounder satellite which they have built, and which will be launched by NASA later this year Both these programmes originally received some impetus from COSPAR recommendations on international co-operative programmes

---

* Part II will be published in *Nature* of August 11

The Soviet Union's report, presented by Academician A A Blagonravov, who is one of the vice-presidents of COSPAR, summarized results from 115 sounding rocket flights carried out from Franz Josef Land, from the European part of the U S S R , and from expeditionary ships in the Pacific, for the measurement of upper-atmospheric temperatures, pressures, winds, state of ionization, and composition, these last-named revealing the presence of helium in appreciable quantities at heights above several hundred kilometres Some of the firings were conducted during the solar eclipse of February 15, 1961, to study the radiation from the solar corona and its interaction with the upper atmosphere during totality The U S S R report also referred in some detail to the instrumentation and performance of the Soviet Venus probe of February 12, 1961, including pressures, temperatures, magnetic fields and variation thereof in the range from several gammas to several tens of gammas, cosmic rays, interplanetary gas, and solar corpuscular streams with flux densities up to 10^9 particles cm^{-2} sec^{-1} The report also described the epoch-making manned orbital flights of Gagarin and Titov which Titov covered in greater detail at the session on Life Sciences Further results from measurements made with instruments on the *Spacecrafts I* and *III* were reported on the energy spectra of groups of nuclei by atomic weight, the composition of primary cosmic rays, the space and time distribution of particle fluxes at heights of several hundred kilometres, and the quick increases in flux connected with bursts of solar activity Information on the Soviet visual and optical tracking net was presented, together with a statistical summary of observations

Dr Richard W Porter, who is the other vice-president of COSPAR, presented the report for the United States A statistical summary covered 70-odd large sounding-rockets which carried scientific payloads to altitudes ranging from 130 to 7,000 km, and 866 smaller meteorological rockets for measurements of pressure, temperature and winds in altitude regions up to 60–100 km, more than 300 high-altitude balloons, and the successful launchings of 31 instrumented satellites and space probes From the point of view of quantity, work with balloons has been chiefly concerned with cosmic ray and upper-atmosphere measurements, but the report also remarked on the publication of final results from the very high quality direct photographs of the Sun obtained with Princeton University's *Stratoscope I*, and on physiological measurements and space suit tests made with the U S Navy's *Stratolab V* The systematic firing of small meteorological rockets has made possible the making of synoptic maps of the 30–60 km regions, a level very important as a transition region through which some of the immediate effects of solar radiations are propagated from the top downwards. Other rocket measurements in ionospheric physics, ultra-violet, X-ray and γ-ray astronomy will be treated more fully in Part II

The review of American satellite programmes for 1961 and early 1962 included a synopsis of cloud-mapping and infra-red radiation balance results from the *Tiros* weather satellites, the analysis of the effects of the periodic daily and seasonal variations in air density at altitude from the drag on satellite motions, especially *Echo I* and *Explorer IX* (4-metre plastic sphere), ionospheric electron temperatures and ion density profiles from *Explorer VIII*, ionospheric structure deduced from propagation effects of radio-frequency radiation in the range 18 kc/s–40 Mc/s, especially with *Lofti* and satellites of the *Discoverer* series, the mapping of circumterrestrial plasmas and magnetic fields with *Explorer X*, γ-ray mapping of the sky with *Explorer XI*, solar radiation measurements with the Solar Radiation Satellite and with the Orbiting Solar Observatory, launched in March 1962; the determination of the particle energy spectrum and associated magnetic fields out to about 13 Earth-radii carried out with *Explorer XII*, and cosmic ray experiments on some of the *Discoverer* satellites The American man-in-space programme and a few important ground-based experiments related to the space programme were mentioned, especially work in meteorite analysis and in methods of sterilizing payloads that are to be landed on the Moon or planets Dr Porter concluded with a very brief outline of plans for the immediate future and a plea for even greater and more intimate degree of international co-operation, and promised that the United States would continue, or possibly improve on, its already good record in this regard

Third International Space Science Symposium

The Space Science Symposium was attended by more than 500 registered participants and observers from 30 countries Scientists from 14 of these presented an impressive total of 141 papers, distributed into sessions under the following headings (the figures in parentheses indicate the number of papers in each session)

I Upper Atmosphere and Exosphere of the Earth and the Relationship to Solar Disturbances (54)
II The Sun and the Interplanetary Medium (31)
III The Moon and Planets (22)
IV Galactic and Extragalactic Astronomy (8)
V Life Sciences (9)
VI Technologies of Space Research Payload Instrumentation (14)

The apparently somewhat unbalanced distribution among the foregoing subjects reflects the influence of two factors In view of the fact that space research activities are growing at an ever-increasing pace, the programme committee had earlier concluded that in the future it will probably be impossible to cover the whole field of space research every year, and had tentatively agreed to limit the session to a number of selected topics (as indicated by the session headings) Some of these topics would be covered almost exclusively by a small number of invited papers, others by an introductory review paper together with shorter reports on really recent results The other factor was that most of the recent results, it so happened, fitted best into category I The papers had undergone a fairly strict process of selection, a fact which was reflected in their exceptionally high average quality About half the papers were presented by American authors, the U S S R , with 31 papers, made a very strong presentation, while the next largest contributions came from Japan, the United Kingdom, France, Germany and Sweden Authors from Argentina, Belgium, Canada, Czechoslovakia, Greece, The Netherlands, and Poland also presented papers

With such a large ground to cover, this report must limit itself to a few selected topics for more detailed treatment. Omission of a particular paper should not be interpreted as being less important or less representative than those included, but only because I am less familiar with what was reported.

Session I. The Upper Atmosphere and Exosphere

This session began with an invited address on "The Dynamics of the Upper Atmosphere" by Prof. J. Blamont (Observatoire de Meudon, near Paris), who is chairman of the Panel on Synoptic Rocket Soundings of COSPAR'S Working Group II (originally on Scientific Experiments, but now renamed W.G. for the International Quiet Sun Year (IQSY)). This paper discussed the structure of the upper atmosphere, as tentatively deduced from data obtained with grenades and drifting chaff (covering the region up to 90 km), the drift of natural meteor trails observed either visually or with radar (80–100 km), and the behaviour of sodium vapour trails in the rocket experiments at Wallops Island, Woomera, Sardinia, and North Africa (up to about 130 km). Certain regularities begin to appear. There is a decided horizontal stratification, such that successive layers have rather different properties. Below 85 km, the trail disappears quickly. In the region from 85 to 101 or 102 km the cumulus-like development of the trail bespeaks a turbulent mixing régime. Above 102 km, the spreading of the trail is very smooth, implying diffusive equilibrium at that level. The boundary between the two regions appears to be no more than 100-m thick. Regularities in the velocity and direction of the upper atmosphere winds as a function of height and time, and correlations between the wind patterns at two different places are now becoming clearer.

In general, there are no large shears above 130 km, but there are wide variations in velocity and direction in the 90–130 km region, which show a correlation with similar variations at nearby localities that fade gradually to zero at about 400 km. But the pattern of these oscillations is rather similar for points at the same latitude half a world apart. The wind vector above 90 km has rotational components with 12- and 24-h periods, and the direction of the rotation and the vector amplitude between 90 and 130 km correspond to the values predicted from the tidal model. Above 130 km, the wind vector rotates in the opposite sense, which implies some other (perhaps hydromagnetic) mechanism. There is some evidence that the very thin ionized sheets of sporadic *E* found by rockets several times within a kilometre or so of 101 km may result from the concentration there of ions moving with the wind through the geomagnetic field, but in opposite directions above and below this level, in such a sense as to be driven upward from below and downward from above.

Papers immediately following, given by G. V. Groves (Great Britain) on Australian rocket results up to above 100 km and by G. I. Golyshev *et al.* (U.S.S.R.) on stratosphere results obtained from rockets launched from the ship *Ob* in the extreme south-eastern Pacific, gave detailed data related to these same questions.

K. Y. Kondratyev (U.S.S.R.) presented two papers, one of which was a series of detailed calculations of the angular distribution of outgoing thermal radiation as a function of wave-length, based on a model using the latest infra-red absorption data for the atmosphere.

A number of papers dealt with chemical composition of the upper atmosphere as it varies with height. A paper by V. G. Istomin and A. S. Pokhunkov (U.S.S.R.) reported on the abundance of the ions NO$^+$, O$_2^+$, O$^+$, N$_2^+$ and N$^+$ that they derived from rocket-borne mass-spectrometer data. They found a diurnal variation for the first three in the 100–200 km region, and the constant absolute concentration of N$^+$ which they found over the range 300–500 km they attribute tentatively to the high temperature at which they may be formed. In a fairly narrowly limited region at 101–105 km, Istomin found abnormal concentrations of Mg$^+$, Fe$^+$ and Ca$^+$, at concentrations of 10^{-4} cm^{-3}, which is about equal to the average night *E*-layer electron concentration, both the altitude and the identity of the ions strongly suggest a meteoric origin, and the ion concentration suggests that meteors play the principal part in maintaining the night *E*-layer.

A. E. Mikirov (U.S.S.R.) reported on sky-brightness measurements from 80 km and higher which can best be explained by the presence of aerosols of the order of 1μ in diameter with a concentration of about 10^{-3} cm^{-3}.

Gordon Newkirk and J. A. Eddy (High Altitude Observatory, Colorado) analysed their photometric measurements of the solar aureole obtained with a stabilized balloon-borne solar coronagraph at heights up to 25 km, they calculated the distribution in size and concentration of aerosols and conclude that since the concentration in the diameter-range 0.2–5 microns far exceeds what could be borne aloft by air currents and diffusion the aerosols must be micrometeoritic infall.

Aono and Hirao (Radio Research Laboratories, Japan) discussed their findings from a variety of different ionospheric probes carried on nine different rocket flights to heights up to 350 km, the most striking feature of their results was an excess of ions over electrons in the 100–115 km region. Bourdeau and Bauer (Goddard Space Flight Center, NASA), combining rocket measurements from above the *F*2 maximum with *Explorer VIII* results, show that the 1,000-km region is nearly isothermal, but the temperature varies with local solar time and activity, more important, they showed the existence of a region in which He$^+$ is the predominant ion, above the O$^+$ layer and below the protonosphere. Pokhunkov gave results from rocket-borne mass-spectrometer measurements which showed evidence of gravitational separation of several elements and molecules.

Several other papers reported on ionization densities deduced from propagation phenomena. for example, the steady night-time value of 3 × 10^4 electrons/cm^3 above 600 km, with an occasional peak in the auroral zone up to 2 × 10^5 (Ulwick and Pfister, United States, using 7.2 Mc/s *Discoverer* data), three absorption maxima per day recorded at Athens with a 58 Mc/s riometer (Anastassiades), a thorough analysis of Faraday rotation effects (Argence, France, and Rawer, Germany), and an electron profile from 100 km to 5,000 km obtained with incoherent scatter radar in Peru, giving a concentration of 10^5 at 600 km, 10^4 at 100 km, and 10^3 at 4,000 km, with evidence from the scatter spectrum that the protonosphere begins at about 2,000 km (K. Bowles, U.S. National Bureau of Standards). These papers were followed by several others which examined the fine structure of the ionosphere: radar studies of aurora-related structures, showing evidence of alignment with the geomagnetic field, and having r.m.s. velocities of about 100–200 m/s deduced from fading frequencies (Egeland, Ortner, and Hultqvist, Kiruna, Sweden); evidence for ionospheric irregularities from thousands of km down to 1 km in diameter, deduced from the time constant and magnitude of the angular refraction of 20 Mc/s signals from *Sputniks I–III* and *Explorer VII* (Paetzold and Zschorner, Germany); the existence of ducted modes of propagation due to parallel field-aligned irregularities spaced several km apart in the 300–1,000 km region, detected with a rocket-borne topside sounder (Van Zandt *et al.*, NASA).

A thorough and interesting theoretical study by Y. L. Alpert *et al.* (U.S.S.R.) described the wake produced by a satellite moving through a plasma and a magnetic field with a velocity much greater than the thermal velocity of the plasma particles, taking into account the electric field resulting from the charge on the satellite. The scattering cross-section of the disturbance is much greater for a body moving parallel to the field lines than across them. They programmed a computer with their formulæ to calculate the effects to be expected for altitudes in the range 300–700 km.

Papers by Groves and McDermott (University College, London), L. G. Jacchia (Smithsonian Astrophysical Laboratory), D. G. King-Hele (Royal Aircraft Establishment, England), O'Sullivan, Coffee and Keating (NASA, Langley Space Flight Center), H. K. Paetzold (University of Cologne), and Harris and Priester (NASA, Goddard Space Flight Center) all examined various aspects of the relationship between solar radiation or disturbances and the heating of the upper atmosphere, as shown by variations in atmospheric drag on satellites. Groves and McDermott deduced a close correlation between air density derived from the motion of *Discoverer XVIII* and the geomagnetic K_p index.

Jacchia, using the motions during 1958–61 of eight different satellites, with perigees of 350–750 km, finds that Nicolet's 1961 model atmosphere, based on diffusive equilibrium in which helium plays an important part, is consistent with his results, that the 27-day density oscillations previously discovered correspond to a temperature variation of 2·5° times the F_{10} flux index of 10·7-cm solar radiation, that diurnal sub-solar bulge lags 30° behind the sub-solar point on the average, and that both Paetzold's semi-annual effect and the secular decrease in density since solar maximum should probably be attributed to the varying level of corpuscular flux and the heating it produces. Similarly, Paetzold has with considerable success separated the effects that are correlated respectively with solar decimetre radiation, solar altitude, and the aspect that the Earth presents to the moving interplanetary plasma, the measure of his success being that he feels that he can predict the drag with an error of less than 15 per cent, although the temperature in the exosphere varies between extremes of 600° and 3,000° K and the density by factors up to 100. O'Sullivan, Coffee and Keating's results, based on the motion of *Explorer IX* (4-metre plastic sphere), also bear out the foregoing results; they found a decrease in density at 700 km by a factor of 10 between 1958 and 1961.

King-Hele carried out analysis of the variation in scale height in the 200–500 km region during the period 1958–61, using the decrease in perigee height and period of 14 satellites with nearly circular orbits; at 275 km the scale height decreased from 60 to 40 km during this time. (King-Hele also gave one of the three invited evening lectures, in which he explained these results in a slightly more popular way, adding by way of context a very lucid and masterly summary of practically everything that has been learned about the upper atmosphere during the past several years.) Finally, Harris and Priester described a model of atmospheric heat balance which takes into account heating by solar extreme ultraviolet radiation and by corpuscular radiation, showed tables of physical parameters as function of local time and height calculated on this model, and compared them with the observations.

The next group of papers was concerned with the complicated relationships between reaction-rates, chemical composition, incident and emitted radiation, differential escape-rate, and so on, as they affect the state of the upper atmosphere. V. I. Krassovsky's paper provided a comprehensive introductory review. A. D. Danilov's paper derived ionization and recombination co-efficients in the 100–400 km region from the day-to-night variation of electron densities, and concluded that the large cross-section demanded suggests that the incident flux responsible for ionization is composed of soft electrons. Both Hanson (United States) and Ivanov-Kholodny (U.S.S.R.) dealt with a reconsideration of earlier models in the light of new data. Nicolet (with Kockarts, both of Belgium) described a model atmosphere which took into account the production of ^{3}He and ^{4}He, the diffusion of these and H through the atmosphere, and their rate of escape, all as a function of temperature, leading to vertical profiles for these elements. The vertical distribution of O, OH and other elements contributing to the line emission spectrum of the airglow as deduced from photometric measurements was discussed by Miss Tarasova; of particular interest is the evidence for concentration of OH in a layer at 73–100 km.

NATURAL RESOURCES OF THE MOON

By Dr. JOHN W. SALISBURY
Lunar-Planetary Exploration Branch, Geophysics Research Directorate, Air Force Cambridge Research Laboratories, Bedford, Mass.

THE importance of lunar natural resources for the future of space exploration can scarcely be exaggerated. Lunar resources will not only play an important part in the establishment of a lunar base by providing life support materials and vehicle fuels but will also be an important, and perhaps a limiting, factor in the logistics of interplanetary space exploration. Certainly, only the most cursory exploration of the solar system could be conducted using either existing or planned propulsion systems so long as the rocket vehicles must lift all their fuel from the surface of the Earth. A lunar fuel source, on the other hand, would provide an extremely convenient low-gravity refuelling station in space.

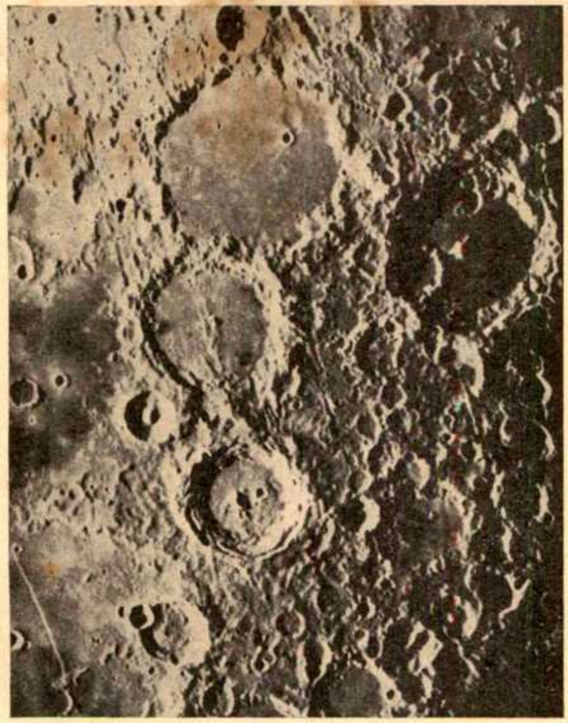

Fig. 1. The crater Alphonsus (slightly left of centre), where Kozyrev reported a cloud of luminescent gas associated with the central peak. Alphonsus is 120 km. in diameter. (*Photo: Mt. Wilson Observatory*)

Despite its smaller size, it is even less practical to make a random search for resources on the Moon than it would be to do so on Earth because of the immensely greater expense involved. It is necessary, therefore, to develop and test reliable theories of lunar mineral deposition which will predict the location of valuable mineral deposits, so that the search for lunar resources may be directed to the most promising locations.

It should be noted that, although limited amounts of useful materials, such as water, should be present in the solid state in permanently shadowed zones on the lunar surface[1-3], such mineral deposits are not considered here to be significant as lunar resources. Though relatively common, they would be small, scattered and, except at the poles, more or less random in their location. Thus, mining such deposits would not generally be economical, and they would probably correspond in usefulness to pegmatite deposits on Earth.

To be actually useful in lunar and interplanetary exploration, mineral deposits must be large, centralized, and predictable in their location. It is the purpose of this article to attempt to predict the nature and location of such deposits, and to speculate on the major processes acting in their formation.

In an investigation of the nature of lunar resources, it is necessary to define what would comprise a mineral deposit on the Moon. Certainly the richest vein of gold could not be economically mined, nor could most of the minerals which are typically of high value here on Earth. Water, on the other hand, would be extremely valuable, for several reasons. After hydrolysis, the oxygen obtained from water would also be a critical supporter of life, and the hydrogen and oxygen could provide a base reserve power supply stored in fuel cells. It appears, therefore, that at least during the early decades of space exploration, water will be the most valuable of all substances on the Moon.

Having established that water is the most valuable resource to have on the Moon, it becomes necessary to determine what evidence exists to suggest where to find it in large centralized deposits.

The first line of evidence is Kozyrev's[4] observation in the crater Alphonsus (Fig. 1) of a gas having spectral emission lines characteristic of the C_2 molecule. The C_2 molecule has been explained by Urey[5] as forming from acetylene, which could have been produced by the action of water on calcium carbide.

A second line of evidence indicating the presence of water deposits is suggested by the lunar chain

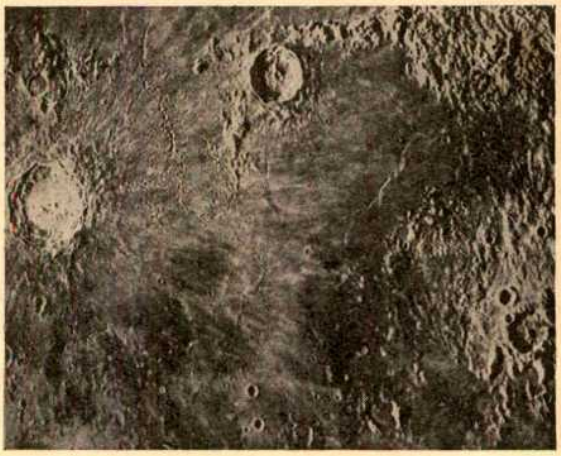

Fig. 2. Chain craters (upper left) running north–south between the craters Copernicus (extreme left) and Eratosthenes (top centre). Copernicus is 90 km. in diameter. (*Photo: Mt. Wilson Observatory*)

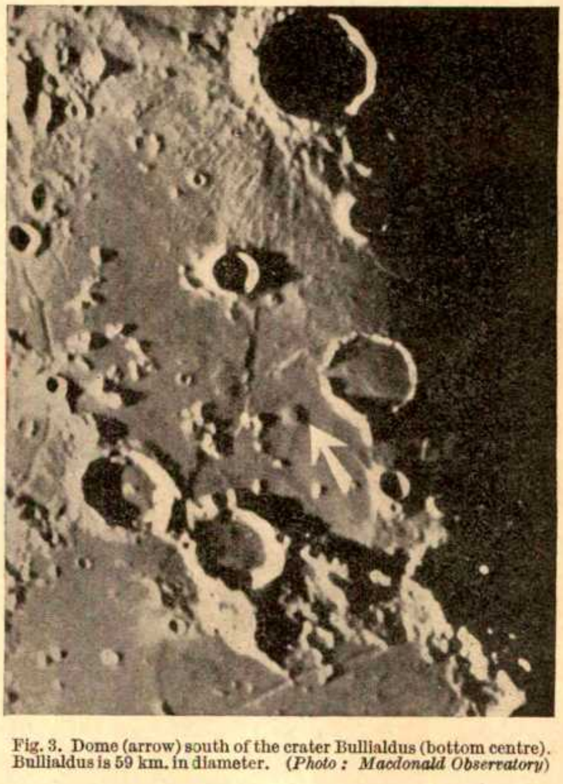

Fig. 3. Dome (arrow) south of the crater Bullialdus (bottom centre). Bullialdus is 59 km. in diameter. (*Photo: Macdonald Observatory*)

craters. Perhaps the best-known example of this phenomenon is the group of chain craters running north–south between the craters Copernicus and Eratosthenes (Fig. 2). In discussing the origin of these features, Baldwin[6] stated that chain craters rarely, if ever, show raised rims and are thus set aside as a distinct class from the majority of normal craters. He also stated that there does not seem to be any question but that they are volcanic blowholes of some kind and are directly the products of gases contained in the lunar crust. Recently, Hibbs[7] has suggested that such craters could have been formed by the impact of meteorites which were fragmented by gravitational forces as they approached the Moon, but this seems very unlikely. If, then, chain craters indicate release of gas, the question remains as to whether or not water was a major component of this gas. Here, one may fall back on a terrestrial analogy, noting that water is by far the most abundant volatile substance involved in volcanism on Earth. In addition, one may again refer to Kozyrev's[4] observation, as interpreted by Urey[5], indicating that water is involved in at least one gas release from the lunar interior. It appears a reasonable assumption, therefore, that a large amount of water was associated with the production of chain craters, and that some of this water is still available in some form at chain crater locations. Again following a terrestrial analogy, it is a reasonable supposition that the initial fumarolic phase of release of hot gas in crater formation would slowly degenerate into a hot spring phase of liquid flow, followed by a cold spring phase and then quiescence. This last phase would probably entail gradual sealing off of the liquid flow channels with deposits of dissolved minerals, most likely quartz. Considering that the present steady-state lunar subsurface temperature is between −23 and −50° C. (refs. 8–10), there might possibly be large deposits of ice sealed off beneath the surface during this process, depending on past and present lunar thermal gradients. Certainly considerable amounts of hydrated minerals suitable for simple water extraction would be expected.

A final line of evidence suggesting the presence of large amounts of water beneath the lunar surface is supplied by the maria domes and wrinkly ridges. I have suggested in a previous paper[11] that the increase of volume due to serpentinization (hydration) of olivine by slow water leakage from the interior could be the cause of lunar domes. Urey (personal communication) has extended this concept to apply also to the origin of wrinkle ridges. If these hypotheses are correct, two additional lunar water deposits are identified, although here the element of doubt is much stronger than in the case of the chain craters.

Despite an element of doubt, it would seem that there is good evidence for the presence of large, centralized, sub-surface water deposits on the Moon. This being so, it seems pertinent to speculate at this time about the possible origin of the water in these deposits, and especially about any possible interrelationships between deposits.

One characteristic of chain craters which may be related to their origin is their association with rilles, which are linear depressions in the lunar surface. Each chain crater depicted in Fig. 2, for example, is connected by a rille. At the northern end of the line the individual craters begin to merge until they almost take on the appearance of a normal rille extending out into Mare Imbrium (Fig. 4). Many other examples can be cited of rilles with similar craters spaced along their length or at their beginning and end (Fig. 5).

Rilles appear to bear a relationship to lunar crustal fractures, as well as to crater chains. Fig. 6 demonstrates that rilles commonly parallel the lunar conjugate fracture system, which has been mapped by Bulow[12], Fielder[13], Hackman[14] and others.

According to Baldwin[6], not only the orientation but also the location of rilles is important He pointed out that the rilles, though subsequent to the maria, are so clearly associated with their margins that some characteristic of the maria must have been the cause of these features. The same marginal association is also commonly true of domes and

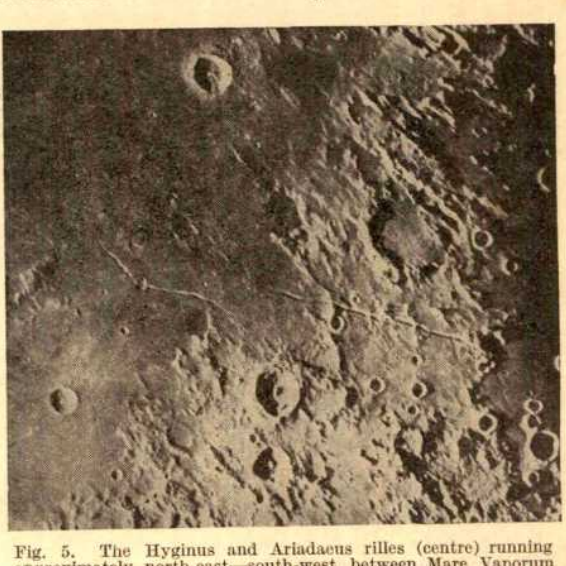

Fig. 5. The Hyginus and Ariadaeus rilles (centre) running approximately north-east—south-west between Mare Vaporum and Mare Tranquillitatis. Mean rille width approximately 8 km. (*Photo: Mt. Wilson Observatory*)

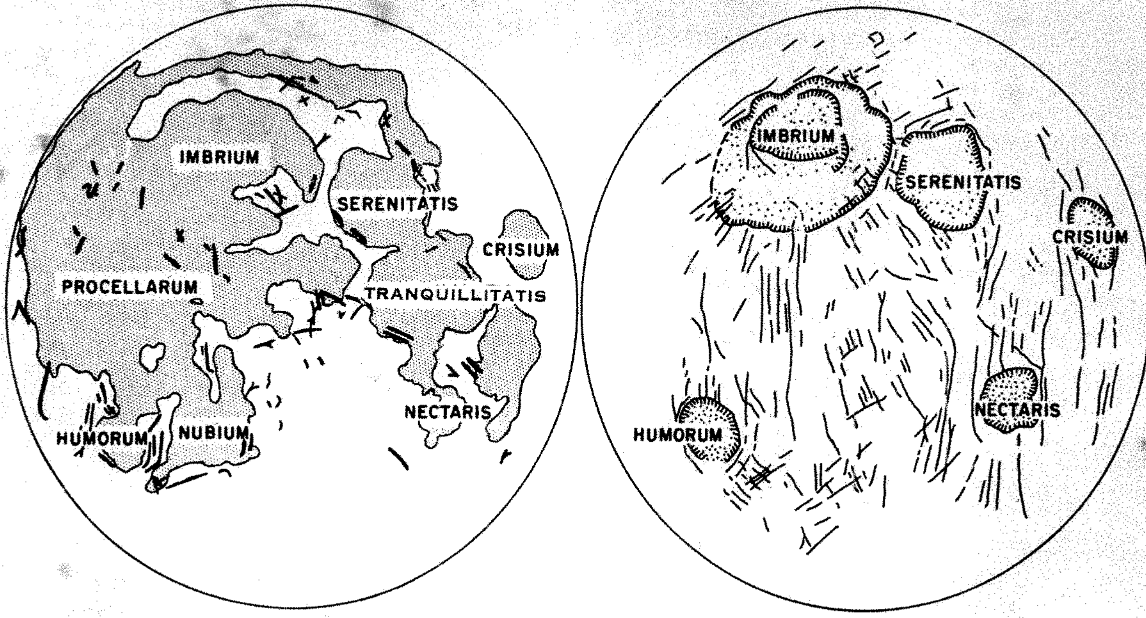

Fig. 6. Distribution of major lunar rilles (left), modified from Baldwin (ref. 6). Simplified lunar tectonic pattern (right), modified from Bulow (ref. 12)

wrinkle ridges, leading to the same conclusion as to their origin.

The origin of all the interrelated features discussed here, and the probable water deposits associated with them, can be explained as resulting from processes acting during and after the formation of the maria. All major theories of maria origin hold that they are composed largely of lava. Some disagreement remains, however, on the internal structure of maria in general, and of some maria in particular. Even so, a reasonable hypothesis is that the circular maria are not made up of many thin layers or sheets of lava, but originated as giant lava pools (ref. 6 and Lowman, 1962, unpublished).

A very idealized lava pool is followed through its cooling cycle in Fig. 7, during which the following phases might be expected to occur:

Phase 1. The lava pool is created and then forms a highly vesicular crust.

Phase 2. The vesicular crust acts as a slowly thickening insulating blanket, sealing off the pool from the surface, causing the rate of cooling to drop sharply. It would then be expected that crystallization processes would follow those of a buried magma chamber (for example, Stillwater Complex, Skaergaard Complex). Normally, this appears to involve initial formation of high-temperature minerals, their settling through the melt to the bottom of the pool, and slow differentiation of the melt as lower and lower temperature minerals are formed and withdrawn from the remaining liquid as it cools.

Phase 3. Reduction in volume with crystallization will produce sinking of the central portion of the crust. Thus, volatile constituents of the magma, which are largely excluded from the crystallized minerals, are gradually segregated near pool margins.

Subsequent to formation of maria and concentration of volatile substances near maria margins, as described here, it is suggested that lunar seismic shocks produced by meteoritic impacts or internal disturbances revitalized pre-existing fractures in the lunar crust. Such revitalized fractures were then able to tap many of these gas concentrations. Rapid escape of this gas produced circular blowouts (chain craters) along some fractures, which commonly were so closely spaced as to produce a general widening of the fracture to form a rille. Fracture widening would be aided by graben-like collapse with the release of pressure. Slow leakage of this gas, on the other hand, would produce either wrinkle ridges or domes as a result of a hydration process. Water remaining below the surface to-day might cause the release of

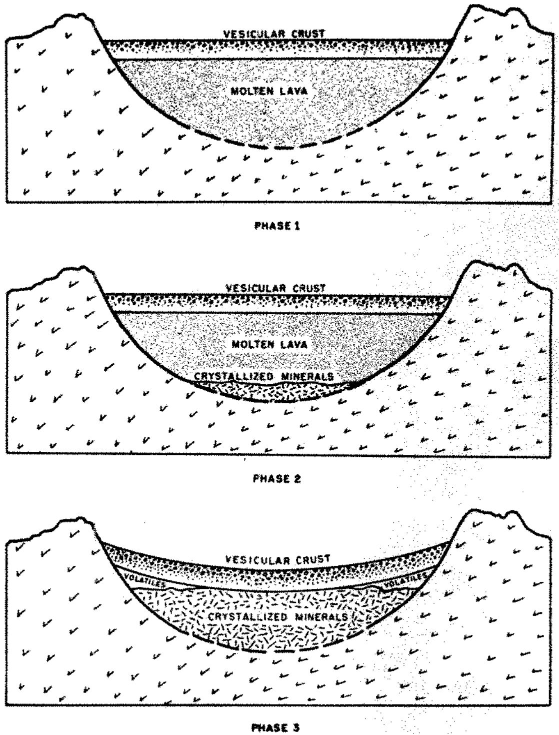

Fig. 7. Phases in the creation of volatile concentrations at maria margins. Mare is several hundred km. in diameter; vertical scale greatly exaggerated

acetylene from silicon carbide It is of interest in this regard to note that Alphonsus, site of a present-day release of gas, has associated with it both a crater chain and at least three rilles

Continuing experimentation is, of course, required to verify the speculations outlined here The lunar seismic experiment proposed by Press *et al*[15] may accomplish this, or at least give rough indications of structure It is especially important that more advanced lunar probes, such as *Surveyor*, do some of their proposed core drilling in the vicinity of rilles for more definite information Other techniques sensitive to water or hydrogen, such as neutron albedo measurements, would most appropriately be used over rilles, domes, wrinkle ridges, and chain craters

I thank Paul D Lowman, Eugene M Shoemaker, Robert C Speed and Roger A Van Tassel for helpful suggestions

ASPECTS OF THE LIFE AND WORK OF JAMES CLERK MAXWELL*

By Sir JOHN RANDALL, F R S

King's College, University of London

THIS article, unlike others of the series, has as its object the consideration of Maxwell's own life and work rather than the consequences of his scientific genius, and for an obvious reason pays particular attention to Maxwell's association with King's College, London, during the greatest period of his scientific life

I shall begin with a minute of the College Council of July 13, 1860, which records a report of the Committee appointed to consider the applications sent in by candidates for the chair of natural philosophy There were five in number, but their names, apart from that of the successful candidate, were not recorded Committees were apparently less assiduously attended in those days, for the minute continues

> " 3 That Mr Green, the only member of the Committee who was present, saw these gentlemen and with the assistance of Professors Hall and Miller very fully considered their merits
>
> 4 That Mr Green, Professors Hall and Miller, unanimously concur in recommending Mr James Clerk Maxwell, Second Wrangler and Second Smith's Prizeman in 1854, late Fellow of Trinity College, Cambridge, and now Professor of Natural Philosophy in the Marischal College and University of Aberdeen, for the Chair of Natural Philosophy in this College "

It was resolved by the Council to elect Mr James Clerk Maxwell to the professorship of natural philosophy Maxwell was twenty-nine years of age and remained at King's College, London, for five years Nevertheless, it was during this brief period that some of his most important work was carried out It was from King's College, London, that his paper "Physical Lines of Force" (1862) and his greatest paper, "A Dynamical Theory of the Electromagnetic Field" (1864), were published This paper contains not only the famous equations of the electromagnetic field but also the substance of the prediction of the electromagnetic theory of light During the King's College period Maxwell also took part in the determination of the absolute unit of resistance, and carried out accurate colour-box measurements on the response of the normal and colour-blind eye His important investigations of the dynamical theory of gases and experimental work on the variation of viscosity of gases with temperature and pressure also belong to this period Furthermore, note-books in the possession of the College show that Maxwell planned his famous *Treatise on Electricity and Magnetism* in London (Fig 1), although it was probably only worked out in full during the period of retirement at his home, Glenlair, from 1865 until 1870 The *Treatise* was published in 1873 during Maxwell's tenure of the chair of experimental physics at Cambridge

While it is difficult in 1962 to say anything outstandingly new or original about Maxwell, I hope, perhaps by virtue of my own association with King's College, London, since 1946, to add something useful to what has already been said

Maxwell has been described by his biographers as one who has enriched the inheritance left by Newton and has consolidated the work of Faraday, a man of profound and original genius and one who was also one of the best men who ever lived

James Clerk Maxwell was born in Edinburgh on June 13, 1831, the son of rather well-to-do middle-class parents After marriage, Maxwell's parents had moved to the estate of Middlebie on the borders of Dumfriesshire and Kirkcudbrightshire Here, at Glenlair, J C Maxwell spent his early years and received his early education at the hands of a private tutor He seems to have shown considerable interest in, and curiosity about, his surroundings and was always asking questions it is difficult to know whether he showed outstanding characteristics at this age, since the official account is somewhat submerged in Victorian piety and adulation

From the age of 10 to 13 Maxwell was a pupil at the now well-known Edinburgh Academy which had been founded in 1824. He does not seem to have been happy in these surroundings, where his country ways and clothes were the object of much ridicule and where he was given the nickname of 'Dafty' While still at school he wrote a paper of a geometrical character that was accepted through Prof Forbes for reading before the Royal Society of Edinburgh During 1847–50 he attended classes at the University of Edinburgh, where he studied, among other things, certain aspects of physics, chemistry and mathematics In October 1850, Maxwell entered Peterhouse at Cambridge, but later moved to Trinity, where there were said to be greater prospects of obtaining a mathematical fellowship In 1854 he graduated as Second Wrangler in the Mathematical Tripos and was also Second Smith's Prizeman He published in 1856 the essay which won for him the Adams Prize "On the Stability of the Motion of Saturn's Rings"

---

* Based on the first of the lectures delivered at King's College, London, to mark the centenary of the publication of Clerk Maxwell's papers on electromagnetic radiation It is hoped to publish these lectures in book form

In 1856, Maxwell was appointed to the chair of natural philosophy at Marischal College, Aberdeen He held this appointment for three sessions until the professorship was suppressed by the fusion of the two Colleges to form the University of Aberdeen In 1860, Maxwell applied for the chair of natural philosophy at Edinburgh but was unsuccessful His old school friend, P G Tait, was appointed But in the same year he was, as we have seen, appointed to the chair of natural philosophy at King's College, London, a post which he held until 1865 Maxwell, in his short life of forty-eight years, published more than a hundred scientific papers Excluding the geometrical juvenilia, some papers on mechanics and the Smith's Prize Essay already referred to, Maxwell's papers fall into three groups (1) colour vision and optics, (2) molecular theory (including heat and thermodynamics), (3) electricity and electromagnetic theory

Maxwell's prediction that light consists of electromagnetic waves was a consequence of his work on electromagnetic theory and not on optics as such

Colour Vision

It will not be possible here to give an extended account of Maxwell's contributions to colour vision His conceptions followed basically on those of Newton and Young Newton had demonstrated that white light was made up of all colours mixed in proportion, colour vision was essentially subjective This idea led Young, 100 years later in 1801, to suggest that the eye contains receptors for the principal colours, red, yellow and blue, only The sensation of all the intermediate colours is due to the stimulation of these receptors in varying proportions This hypothesis forms the basis of Maxwell's experiments Maxwell carried out his studies of colour vision using a colour top (originated by Young) and a colour box Hopley (thesis, University of London, 1956) considers that Maxwell should be given credit for the following important advances (1) The demonstration that the response of the human eye to coloured light may be predicted to quite a high order of accuracy (2) The development of the colour box and colour top into instruments capable of making measurements with mathematical precision (3) The discovery of the numerical laws for the evaluation of data from such measurements The method of calculation evolved by Maxwell has been used by all subsequent investigators (4) The demonstration that the sensations of all the colours of the spectrum may be simulated by suitable mixtures of three primaries (including subtraction as well as addition) (5) The application of the trichromatic theory to the reproduction of a colour photograph

In his Friday Evening Discourse to the Royal Institution of May 17, 1861, Maxwell demonstrated the three primary colours by means of three lantern projectors before which were placed troughs containing respectively ferric thiocyanate (for red), cupric chloride (for green) and ammoniated cupric sulphate (for blue) A triangle was thus illuminated so that the pure colours appeared at its angles while the rest of the triangle contained the various mixtures of the colours as in Young's triangle of colour

In the same Discourse, three photographs of a coloured ribbon taken through the three coloured solutions respectively were introduced into the projectors, giving images representing the red, green and blue parts separately When these were superimposed a coloured image was seen which, if the red and green images had been as fully photographed as the blue, would have been a truly coloured image of the ribbon

Comparison of Maxwell's colour-box measurements with those of modern workers such as W D Wright shows that Maxwell's results were surprisingly accurate

Kinetic Theory and Thermodynamics

During the year 1859 Maxwell wrote his very important paper on the kinetic theory of gases Although this was published in 1860, the year he came to King's College, London, it cannot be regarded as strictly of this period One has only to look at standard treatises on kinetic theory of the present day to realize how much the subject owes to Maxwell's clear and penetrating analysis Early attempts in this field had been made by Herapath about 1816 In his derivation of an expression for the pressure of a gas Herapath had, however, assumed that all the molecules were of equal velocity Furthermore, in attempting to relate pressure to temperature, he had assumed that the temperature of a gas is measured by the momentum of its molecules The next step in the development of the kinetic theory of gases was chronologically that of Waterston (1846), although his work was not published until the manuscript was disinterred from the Royal Society's archives by the first Lord Rayleigh in 1892 Waterston introduced the idea of groups of the assembly of molecules with the same velocity The group with velocity v_1 would contribute to the pressure an amount $1/3N_1mv_1^2$ and so on The total pressure would be given by $p = 1/3Nmv^2$, where v is no longer the actual velocity of the particles but a mean velocity given by the equation

$$Nv^2 = N_1v_1^2 + N_2v_2^2 +$$

Thus we have the conception of the mean square, v^2, of the molecular velocity

Also due to Waterston is the statement that the mean square of the kinetic energy measures the temperature This leads directly to the laws of Boyle and Gay Lussac Waterston also examined the properties of gaseous mixtures and showed that "the mean square molecular velocity is inversely proportional to the specific weights of the molecules" This was rediscovered by Maxwell fifteen years later

Although Waterston had mentioned briefly some of his ideas and conclusions in subsequent papers, it appears that it was two papers by Clausius in 1857 and 1859 that stimulated Maxwell to take up the study of kinetic theory These were concerned with the part played by rotational energy of molecules in the heat content of a substance, and with the mean free path Maxwell showed how the velocity distribution idea originally introduced by Waterston must be considered statistically and also succeeded in deducing the law of distribution The number of molecules the velocity of which lies between v and $v + dv$, where v is taken in all possible directions, is

$$N \frac{4}{\alpha^3\sqrt{\pi}} v^2 e^{-v^2/\alpha^2} dv$$

where α is related to the mean value of v^2 by the expression $3/2\ \alpha^2 = \overline{v^2}$

In a later part of his paper Maxwell determined the average number of collisions in a given time and hence, from a knowledge of their velocities, the mean free path of the molecules He then proceeded to show how by means of experiments on the viscosity of gases the mean free path could be determined experimentally

Maxwell used a value for the viscosity of air obtained by Stokes and deduced that the mean free path of molecules in air was 1/447000th part of an inch, and that the number of collisions per second experienced by each molecule was about 8×10^9 He also deduced that the viscosity should be independent of pressure This was the origin of his London experiments on viscosity of gases, and of its variation with temperature (Bakerian Lecture, 1865) These were, however, not very accurate

Maxwell published his "Thermodynamic Relations" in the fifth edition of his text-book, *The Theory of Heat* (1877) Hopley points out that he used an effective geometrical method of demonstrating these results, but it is not clear that their derivation was achieved in this way

As Glazebrook and others have pointed out, Maxwell's work on the subject of heat and kinetic theory would in itself have been sufficient to secure for Maxwell a distinguished place among those who have advanced physical knowledge His greatest work, however, his theory of the electromagnetic field, was still to come

Electricity and Electromagnetic Theory

Maxwell's first contribution to the study of electricity was made at the age of twenty-three in a paper on "Faraday's Lines of Force", read to the Cambridge Philosophical Society on December 10, 1855 We find him writing to Thomson (better known by his later title of Lord Kelvin) on February 20, 1854, for advice on the reading of papers on electricity Maxwell corresponded continually with Thomson and Tait throughout his scientific life, and the former in particular had a most important influence on his ideas At a much later date, 1873, Maxwell stated in the introduction to his *Treatise on Electricity and Magnetism* "Before I began the study of electricity I resolved to read no mathematics on the subject till I had first read through 'Faraday's Researches on Electricity'" Although the lives of Faraday and Maxwell overlapped by some 36 years, for only 13 of these could Maxwell be said to be concerned actively with electrical phenomena

It is of great interest to recall the state of the subjects of electricity and magnetism at the time Maxwell wrote his first paper on 'lines of force' Mathematicians had had great success in applying analytical methods to problems of distribution of charge on bodies of various shapes (for example, the work of Laplace and Poisson) Ampère laid the foundation of his theory in a study of the forces existing between circuits carrying current The essence of all this work was embodied in the conception of 'action at a distance' The space outside an electric charge or magnetic pole did not differ on this view from 'empty' space A quite different standpoint was taken by Faraday, who had been making fundamental experimental discoveries on electricity for some twenty years Faraday originated the hypothesis that lines of force spread out in all directions from a point electric charge or magnetic pole In this sense the space surrounding such charged or magnetic bodies differed from other space To Faraday the lines of force had physical properties, they were not just convenient mathematical abstractions They were in a state of tension which was thought to be responsible for the attractive force between charges of opposite sign The energy of the field was also supposed to exist in the space around the lines of force

Faraday was not mathematically minded and there is not an algebraic symbol to be found in his *Experimental Researches* J J Thomson has pointed out that the mathematicians could not understand him and were rather contemptuous of his ideas

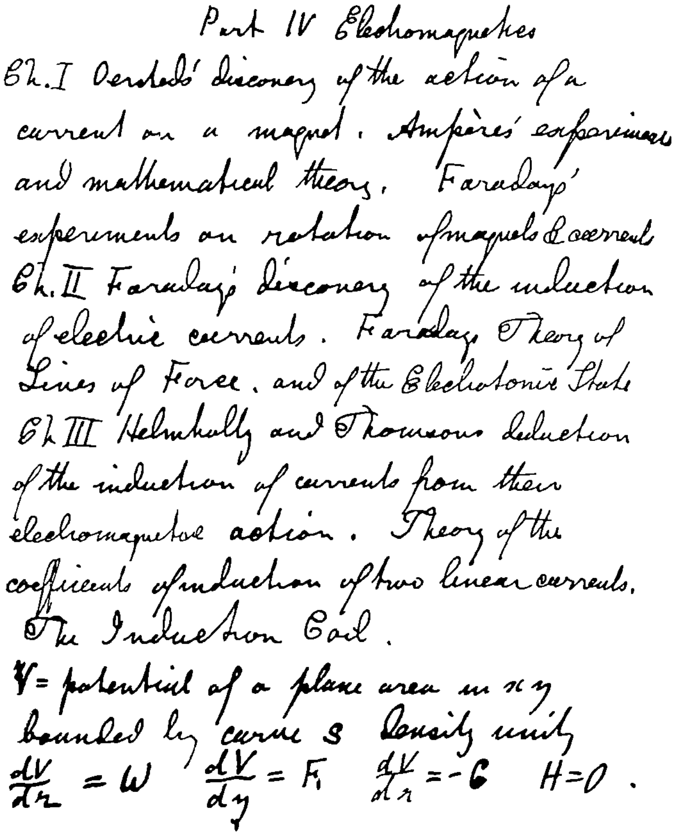
Maxwell's first important contribution in 1855 was to show that for the types of problem so far studied Faraday's views led to exactly the same results as the theory of action at a distance It is a sobering thought to ask which side we would have been on if presented with the same alternatives

Maxwell was a very capable mathematician, but the mathematics was always the servant of the physics He was always keen on the idea of an analogy or a model, and the introduction to his paper on 'lines of force' is very prophetic in this respect

Faraday's outstanding discovery of electromagnetic induction had shown that space occupied by lines of force was different from empty space A circuit rotated in space through which no lines of magnetic force pass will not register an electric current It was thus that Faraday arrived at his idea that space containing lines of magnetic force is in a special state, the 'electro-tonic state'

In his second paper on electrical phenomena, "Physical Lines of Force", published in 1862 during his professorship at King's College, Maxwell laid the foundations of his greatest contribution to electrical theory and devised a model to illustrate Faraday's law of electromagnetic induction In this work Maxwell made use of the analogy between lines of force in the electromagnetic field and vortex filaments in a liquid with finite fixed boundaries In Maxwell's model the lines of magnetic force were represented by cylinders rotating around these lines as axes The magnitude of the force was represented by the velocity of rotation and its direction by that of the axis of rotation

It would take us too far from our present purpose to examine this model in detail Indeed, in the *Treatise* this model, 'the scaffolding of the Theory', as it has been called, is discarded Suffice it to say that to represent a uniform magnetic field Maxwell's cylinders must all rotate in the same direction But cylinders in contact would rotate in opposite directions To achieve his purpose Maxwell introduced into his model small spheres to act as 'ball-bearings'



Part IV Electromagnetics

Ch. I Oersted's discovery of the action of a current on a magnet. Ampère's experiments and mathematical theory. Faraday's experiments on rotation of magnets & currents

Ch. II Faraday's discovery of the induction of electric currents. Faraday's Theory of Lines of Force. and of the Electrotonic State

Ch. III Helmholtz and Thomson's deduction of the induction of currents from their electromagnetic action. Theory of the coefficients of induction of two linear currents. The Induction Coil.

V = potential of a plane area in xy bounded by curve s density unity

$\frac{dV}{dx} = W \quad \frac{dV}{dy} = F_1 \quad \frac{dV}{dx} = -G \quad H = 0$.

Fig. 1. Part of an early draft of the contents of Maxwell's *Treatise on Electricity and Magnetism* taken from his note-books. It is believed to have been written some time between 1860 and 1865 and well before the publication of the *Treatise* in 1873

The ball-bearings were supposed to represent particles of electricity, and their motion an electric current. When the cylinders have the same velocity the ball-bearing has no translatory motion and there is no current. If the speed of one of the cylinders is changed the centre of the ball between them will begin to move. The motion of the ball indicates an electric current. The model thus illustrates Faraday's discovery of the production of electric currents by changes in magnetic force.

J. J. Thomson has stated that this is a very striking illustration of the advantage of using a model. Maxwell designed his model to illustrate Faraday's discovery that changes in a magnetic force produce an electrical force. When he came to use the model he found that it suggested that changes in the electric force would produce a magnetic force. The introduction and development of this idea was one of Maxwell's outstanding contributions to physics. The importance of the theory lies in the implication that all changes in electric and magnetic fields caused waves to be propagated in space. On previous theories waves could not exist. The paper on "Physical Lines of Force" contains a form of the well-known Maxwell equations. In the later paper, "The Dynamics of the Electromagnetic Field", the model is dropped and the Maxwell equations are in effect developed. Both these papers were written while Maxwell was at King's College, and his work in London is therefore unquestionably the most important of his life. Few ideas can be said, however, to belong to a particular period except in a very broad sense. Maxwell was already thinking about lines of force when inspired by Faraday's experimental researches ten years before he wrote his famous paper.

Maxwell's ultimate account of his theory is given in the *Treatise*, published in 1873. Note-books in the possession of the College show that Maxwell was already planning this work when in London, and it is of interest to compare the titles of the chapters as originally planned and the chapter headings of the published work (Fig. 1). It is particularly interesting that the contents at this stage betray no mention of his own electromagnetic theory.

Maxwell's theory was not very enthusiastically received either in Great Britain or on the Continent. This was due in part to the extremely obscure presentation and in part to the earlier success of the action-at-a-distance theory. One of the most controversial ideas embedded in the theory is what Maxwell called a 'displacement of electricity', and he was so guarded in defining what he meant by electricity that his idea was much misunderstood. This obscurity was in Hertz's mind when he said that Maxwell's theory was Maxwell's equations. Helmholtz said he would be puzzled to explain what an electric charge was on Maxwell's theory, beyond its being the recipient of a symbol. A physical interpretation of Maxwell's theory lies in Faraday's lines of force. J. J. Thomson has written that if what Maxwell termed electricity is interpreted as 'lines of force' and what he termed displacement as the 'density' of these, we are able to satisfy the two definite statements in his work: (*a*) wherever there is 'electric force' there is 'electric displacement', (*b*) electricity behaves like an incompressible fluid.

Faraday's law of electromagnetic induction states that the rate of alteration in the number of lines of magnetic induction passing through a circuit is equal to the work done in taking an electric charge round the circuit. Maxwell's law states that the rate of alteration in the number of lines of electric force passing through a circuit is equal to the work done in taking a unit magnetic pole round it. The expression of these two laws in mathematical form gives Maxwell's equations. The two laws just stated are symmetrical.

Maxwell's theory predicts the extremely important idea that electrical disturbances are propagated as transverse waves of electric and magnetic force. The velocity of propagation depends on quantities which can be determined by purely electrical measurements and should be equal to the velocity of light. In a paper published in 1868 Maxwell reported his results on the determination of the ratio of the electrostatic to the electromagnetic unit of electricity (with air as the dielectric). The principle of his method was to balance the attraction between two electrified disks by the repulsion between two coils of wire in which currents were flowing in opposite directions. One of the disks and one coil were placed at one end of the beam of a torsion balance while the other pair remained fixed. A third coil was used to eliminate the effect of the Earth's magnetic field

The result was a value of 2 88 $\times 10^{10}$ cm sec $^{-1}$ compared with that of Kohlrausch and Weber of 3 11 $\times 10^{10}$ The accuracy of Maxwell's result is dependent on that of the British Association unit of resistance—the velocity being represented by 28 8 ohms This work, of course, did nothing to establish the electromagnetic nature of light which was a matter of vital importance for this theory

Not until some years after his death was it experimentally possible to both produce and detect electrical waves when the method of producing them by the oscillatory discharge of a condenser or induction coil became available It fell to Hertz, a pupil of Helmholtz, to show that they could be detected by means of very small electric sparks passing between two metal balls placed close together, Hertz himself believed that in some respects von Bezold had prior claim in his publication of 1870 Simultaneously with Hertz, Oliver Lodge in Liverpool investigated the theory of the lightning-conductor and carried out a series of experiments on the discharge of small condensers which led him to observe oscillations and waves in wires Hertz says of Lodge's experiments "Inasmuch as he entirely accepted Maxwell's views, and eagerly strove to verify them, there can scarcely be any doubt that if I had not anticipated him he would also have succeeded in observing waves in air and thus also proving the propagation with time of electric force"

G F Fitzgerald of Dublin gave two papers of significance in this field at the British Association meeting at Southport in 1883, four years before Hertz's publications appeared The first of these suggested a method of producing electromagnetic disturbances of comparatively short wave-lengths (10 m or less) which involved the discharge of an accumulator through a small resistance Hertz later used this method without knowing of Fitzgerald's experiments and obtained waves of 24 cm length. Fitzgerald's second paper was entitled, "On the Energy Lost by Radiation from Alternating Circular Currents"

By a curious chance my own work has had a connexion with that of Hertz When more than fifty years later it became necessary to produce short electromagnetic waves, not in a broad spectrum but with a precise wave-length and of great intensity, it was to Hertz's resonators that Boot and I turned A single resonator of the cavity magnetron is but a cylindrical extension of a Hertzian dipole

Measurement of Electrical Resistance

No account of Maxwell's work in London would be complete without some mention of experiments he carried out for a Committee of the British Association, Maxwell ultimately became a member of the Committee, the report made by Maxwell and Fleeming Jenkin is published in the *British Association Report* for 1863 To us a century later this work may seem rather small beer But one has only to read this extremely clear account of the fundamentals of electricity to realize that it formed the basis of most of the text-books of the subject for many years to come It had its importance, too, in the establishment of standards and it is of interest to King's College that the measurement of the standard of resistance was carried out in its own buildings in the Strand

Surely enough has been said to give us the impression of a scientific leader of the first order, someone who would come in most physicists' rating very close to Newton and Faraday Einstein has said that the change in the conception of reality brought about by Maxwell is the most profound and the most fruitful that physics had experienced since the time of Newton Maxwell's description of reality is represented in his double system of partial differential equations in which the electric and magnetic fields appear as dependent variables Since Maxwell's time physical reality has been thought of as represented by continuous fields governed by partial differential equations and not capable of any mechanical interpretation The advent of quantum mechanics, rather than the theory of relativity, has produced a situation in which we have to deal with amounts of energy concentrated in small spaces and this is in direct contradiction to Maxwell's equations and to the Newtonian system of mechanics The quantities that appear in the laws of quantum mechanics make no claim to describe physical reality as such, but only the probabilities of the appearance of a particularly physical reality

Whatever the present difficulties and whatever the future may hold, Maxwell's theory will always remain a step of outstanding importance in the development of physical ideas His work has been so important and lasting because it was based on experiment

I wish to return for a brief space to further consideration of Maxwell's position in the study of electromagnetism It is clear, of course, that he did more than anyone else of his time to advance the subject, and this was achieved as a consequence of his recognition (1) that a changing electric field constitutes a current and is accompanied by a magnetic field, (2) that light consists of electromagnetic waves propagated with a velocity of 3 $\times 10^{10}$ cm /sec

Although Ludwig Lorenz in 1867 derived equations essentially equivalent to Maxwell's without any primary hypotheses about the medium, this has largely beeen ignored by the bulk of physicists This is strange because it is clear that the device of a displacement current is thereby rendered unnecessary. Mathematically, it is simply a way of transforming an equation of the Poisson type to one of wave-motion J J Thomson explained Maxwell's displacement current in terms of lines of force But we must recognize that the idea of lines of force came from Faraday and is also hypothetical Thomson thus appears to have fallen into the trap of explaining one hypothesis in terms of another No one seriously denies that the conception of lines and tubes of force is an extremely useful one to the physicist and engineer in the laboratory It was Maxwell's explicit objective to put into mathematical form Faraday's ideas

The work of the German and other Continental physicists contained no hypotheses about lines of force Lorenz introduced the idea of retarded potentials, thus following an earlier (1848) suggestion of Riemann His theory provides for the propagation of electric waves with a finite velocity without the necessity of introducing the idea of a material medium and a displacement current Lorenz, however, failed to make the vital link between the velocity c and that of light It is perhaps for this reason more than any other that his work has been neglected and almost forgotten Maxwell himself in his *Treatise* acknowledges Lorenz's work as being very close to his own It was apparently published without knowledge of Maxwell's two papers Maxwell's theory was not very well understood on the Continent because physicists there were fully attuned to the action-at-a-distance theory and slow to accept the Maxwellian implications of Faraday's lines-of-force hypothesis Lorenz's ideas were, however, the logical development of the Gauss–Weber–Neumann school Yet neither Lorenz's work nor Maxwell's led to an experimental search for electromagnetic waves until 1888, when Hertz carried out his experiments

It is curious that physicists as a whole should have consistently clung to the trappings of Maxwell's theory As a consequence a good deal of confusion in the subject persists to this day It is often said that the object of a theory is to do no more than provide ideas for new experiments This is certainly one extremely important object In Maxwell's case it led to the superb experiments of Hertz However, would not the subject of electromagnetism have benefited enormously if physicists had at any time in the past fifty years taken a fresh look at the premises and hypotheses on which the subject rests ? Considerations of this kind go to the heart of the accepted presentation of electromagnetic theory

Perhaps no better tribute to Maxwell could be made at this time than to re-examine the foundations of classical electricity in terms of the physics of to-day and to state them and teach them in a self-consistent manner

Maxwell as a Teacher

In thinking of any mid-nineteenth-century physicist as a teacher, we have to bear in mind three aspects of significance and importance

(1) *The importance of the laboratory* Laboratories for the teaching of experimental physics, as distinct from the applied mathematics of natural philosophy, were rare In consequence any scientist who wished to teach experimental physics had to provide first of all the laboratory In King's College it appears that some at least of the physics teaching was carried out in the workshop Fees were paid by the students for the use of the workshop The *College Calendar* of the day states that there was a curator of the College Laboratory, which appeared to serve all subjects It seems probable that Maxwell made use both of the College Laboratory and of its workshop for the teaching of experimental physics Although Wheatstone had been appointed professor of experimental philosophy in King's College in 1834, and was given a grant of £50 to cover the cost of apparatus used in his lectures, it seems clear that he did not give courses of lectures for more than a very few sessions Maxwell was certainly teaching experimental physics to evening students at King's College in the session 1864–65 This was nine years before the Cavendish Laboratory was founded under his leadership, and it is not unreasonable to infer that his experience at this time had some influence on his later plans for laboratory design In Scotland, both in the time of Forbes at Edinburgh and Kelvin at Glasgow, students assisted the professor in his experimental work, but this scarcely constituted organized class teaching as we know it While it seems unlikely that Maxwell initiated any new features of laboratory design at King's College, we know from his Cambridge period that he did so there In so far as a good laboratory is essential to good teaching, Maxwell's standard was very high

(2) *The course of study*, especially at a time of change, gives some measure of the mind of the lecturer The course in natural philosophy given in King's College in 1859, a year before Maxwell took up his appointment, was, apart from some experimental lectures on light, entirely concerned with the properties of matter, a little of heat and of elementary astronomy Maxwell's evening class in experimental physics for the session 1864–65 dealt with magnetism and electricity A separate course in statics, dynamics, sound and optics was given by T A Cock Maxwell's course is worthy of a little attention since its content reflects much of what is taught of electricity and magnetism in schools to this day The subject-matter of the syllabus was as follows

I Preliminary mechanical ideas , the three standard measures of length, time and mass , different ways of measuring forces , the gravitation system , the absolute system

II Magnetism , the loadstone , properties of soft iron and steel , action between two magnets , lines of magnetic force , determination of the magnetic axis of a magnet and of its magnetic moment

III Magnetism of the Earth , determination of its direction and intensity at different places , the declinometer , magnetic charts , the work of a magnetic observatory , photographic representation of the magnetic elements , magnetic storms and sudden disturbances , the diurnal and annual variation , the secular variation

IV Magnetism of iron ships , errors of the compass , methods of correction , magnetic induction

V Electrical attractions and repulsions , transference of electricity , conductors and insulators , measurement of quantities of electricity by the statical method

VI Electrical induction , the Leyden jar , electricity produced by work , the electrophorus , Varley's condenser , electric potential , electric capacity , electroscopes and electrometers , atmospheric electricity

VII Electricity in motion , the electric current , relation to statical electricity, to chemical action, to magnetism , Oersted's discovery of the mechanical action between a current and a magnet , Ampère's laws of the mutual action between currents , Faraday's discovery of the production of currents by magnets and by other currents

VIII On the electromagnetic system of measurement , measurement of currents , tangent galvanometer , Weber's electro-dynamometer

IX Ohm's law for the strength of currents , derived currents , Wheatstone's bridge , comparison of resistances by the electrical balance , method of finding the position of a fault in a submarine telegraph cable Siemen's thermometer for deep-sea sounding

X Determination of resistance and other electrical qualities in measures founded on those of length, time and mass The standard resistance unit of the British Association founded on experiments at King's College

XI Heat produced by electric currents , calculation of the mechanical equivalent of heat from Dr Joule's experiments , electric currents in unequally heated circuits , thermo-electric pile

XII The electromagnetic field and its lines of force , exploration of the field by means of magnets , shape of the lines of force , what happens to a magnet, a piece of iron, a piece of bismuth, a conductor carrying a current, a moving conductor, and a beam of plane-polarized light in the electromagnetic field ? effects of a disturbance of the electromagnetic field

XIII Conservation of energy in electromagnetic phenomena , hypotheses about the nature of electromagnetic action

XIV On electric telegraphs

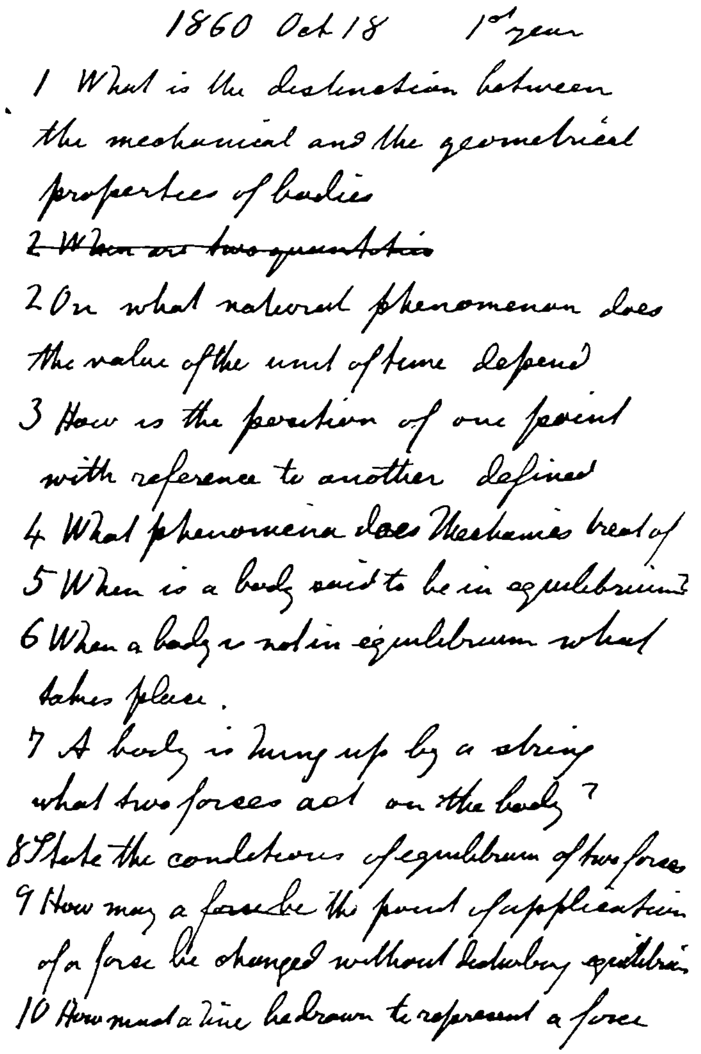
It is immediately apparent that this was and still is in many ways a very good course It is fundamental in outlook, was ahead of its time, and contains for the most part subjects that are still important to-day Maxwell was a close friend of Thomson (Kelvin) and we do not know to what extent the teaching of physics was discussed between these two men. Maxwell was clearly able to design a good course in magnetism and electricity. Fig 2 is taken from a set of the earliest questions set by Maxwell to his elementary students at King's College

(3) *Maxwell's ability as a lecturer* Doubts about this have often been expressed and derive in part from statements made in the *Centenary History of King's College, London,* by F J C Hearnshaw.

> "As a teacher of raw youths he did not prove to be a success He was, says one who knew him, a quiet and rather silent man and it seems not unlikely that the students were too much for him "

The Rev Canon R Abbay, who was appointed a lecturer and demonstrator in physics at King's College in July 1868, wrote to the centenary historian

> "It was difficult to keep order in the class in those days, especially when the blackboard was much used, but probably the disorder led to the greatest scientific discovery of the century It was believed by scientific men that the Governors asked Clerk Maxwell to resign his professorship of physics because he could not keep order; that then he went back to Cambridge and quietly worked out his theory of the æther "



1860 Oct 18 1st year

1 What is the distinction between
the mechanical and the geometrical
properties of bodies
~~2 When are two quantities~~
2 On what natural phenomenon does
the value of the unit of time depend
3 How is the position of one point
with reference to another defined
4 What phenomena does Mechanics treat of
5 When is a body said to be in equilibrium?

takes place.
7 A body is hung up by a string
what two forces act on the body ?
8 State the conditions of equilibrium of two forces
9 How may a force be the point of application
of a force be changed without disturbing equilibrium
10 How must a line be drawn to represent a force

Fig 2 Probably the first questions set by Maxwell to his first-year students in natural philosophy at King's College, London, in October 1860 Taken from a Maxwell note-book in the possession of the College

In a later letter Canon Abbay added

> "It was Professor Clifton who told me—I think in 1869 —that he had heard that Clerk Maxwell had been asked to resign because of the disorder at his lectures "

and he went on to point out that Clifton was in a position to know

Dr G R Wilkinson and I have searched the College minute books and archives for further evidence on this point, but without success Others, we suspect, have been before us, for the boxes for 1860 and 1865 are not to be found

Not all speak of Maxwell as a poor lecturer, he is, for example, praised by Horace Lamb This would only go to suggest, however, that Maxwell could be appreciated by the brilliant student rather than by the less-gifted Stone of Piccadilly (never, so far as I know, a practising scientist) told Prof Derek Price that Maxwell was a bad lecturer

As a teacher of research students there can be no doubt that Maxwell was remarkable for the inspiration he instilled in the course of an hour's discussion

It is unfortunate that the official historian of King's College has left the impression, without adequate evidence, that in 1865 Maxwell was asked to resign his chair on account of his alleged lack of teaching ability and power to keep order in class There is certainly no record even hinting at such action in the minute books of the College Council Hearnshaw, however, accepts the word of Abbay and remarks that Maxwell's departure was thus indirectly of great benefit to science Since Maxwell could equally well have been invited to Cambridge from either London or Glenlair, this point also is of dubious value

Maxwell, as we have seen, had published much of his outstanding work from London The period of retirement at Glenlair was largely occupied with the completion of the *Treatise on Electricity and Magnetism*

Maxwell and the Cavendish Laboratory

The chair of experimental physics was founded in 1871 in circumstances now so well known that I shall not repeat them here Kelvin turned down the offer of the chair and Maxwell, apparently somewhat reluctantly, accepted In a letter written at this time Maxwell points out that he has no experience of teaching experimental physics But we have seen that he did in fact have a course at King's College during the session 1864–65 There seems to be little doubt that Maxwell's ideas on laboratory design owe a great deal to the interest in building matters derived from his father and particularly from what he saw in Glasgow and Oxford, as well as from his own experience After all, he had used apparatus since his undergraduate days with Forbes in Edinburgh The design and construction of the Cavendish Laboratory went on until 1874, when in June of that year it was first used for experiments

Both in design and in the principles of experiment and measurement that Maxwell set out to achieve, the Laboratory set standards which were unexcelled elsewhere for many years Part of this was due to the inspiration and genius of Maxwell himself, part to the coincidence of the unexampled brilliance of his successors, and part to the fact that the time was indubitably ripe for such developments A comparison of the merits and achievements of Maxwell and Kelvin is beyond our present scope, but it may be noted that Kelvin had shown the way to the success of physical measurement and design in the improvement of industry as well as of natural knowledge

It has been remarked that Maxwell showed superb political astuteness in bringing the Cambridge of the day to approve of his plans But is this really so ? Cambridge had founded the chair and had the munificent interest of its Chancellor in the objective before Maxwell ever arrived there Both Maxwell and Kelvin had been gradually steering the Mathematical Tripos examination towards more physical subjects for some years Political manœuvre seems far removed from the recorded impressions of Maxwell's character One is left with the impression that the establishment of the Cavendish Laboratory on a firm basis followed smoothly from the natural and quiet expression of Maxwell's firm convictions It is the great achievement of British science of the period, and was accompanied in Maxwell's inaugural lecture by a set of precepts and principles which have never been matched in their prescience and acuity

Maxwell the Man

So much has been written about Maxwell the physicist that we are left with a rather blurred picture of the man and particularly it seems difficult to place him in relation to the times in which he lived In some senses he was a prophetic genius who was of the nineteenth century but not in it In this he differed profoundly from Kelvin, who began his career with deeply fundamental investigations (such as that which led Maxwell to the discovery of the electromagnetic theory of light) and ended it a very rich man deeply involved in industry Maxwell's genius, like that of Newton and Faraday, was timeless, Kelvin's was of his day Maxwell could always see beyond the investigation of the moment to the implications for the future, in the deepest sense Kelvin could not Maxwell predicted the electromagnetic theory of radiation and thus set in train a series of events that still profoundly affects our daily lives In his famous paper "On the Dynamical Theory of the Electromagnetic Field" he discusses the problem of the gravitational field and thus began the long and as yet unsuccessful attempt to derive a unified field theory of matter

But again, what of the man ? Physically he was of middle height and classic features with deeply penetrating eyes set off by black hair and beard He had a quiet ironic sense of humour which is clearly evident from his well-known occasional verses But above all Maxwell was a deeply religious man who seems to have accepted the tenets of the Christian faith from an early age Many of the letters from Maxwell to his wife that appear in the official *Life* are in effect sermons discussing various aspects of the *New Testament* It is unfortunate that there are virtually no letters from Mrs Maxwell on record, either none was preserved or they were thought to have been irrelevant to the major theme We are left in ignorance, and so we cannot know Maxwell cared deeply for his wife, who had indifferent health for many years and who surprisingly survived him Even as he lay dying he gave orders for her comfort Although Maxwell was so religious there is not much evidence that he was interested in the philosophy of his day, indeed, interest in the one was his philosophy and precluded the other As J G Crowther has pointed out, this probably led to a greater concentration on scientific matters

Religion was a deep and driving interest to many Victorians It was an age characterized by tremendous industrial development and consequent economic circumstance The middle classes were confirmed in their status and the mild feudal atmosphere in which Maxwell was brought up received no jolts There were no deep scars of war to distract an intellectual from his chosen task Both at Dalbeattie, at Cambridge and in London Maxwell had time to think, and thought to some purpose Maxwell liked to lecture to working men, and this he did both in London and in Cambridge But we are left with no account of his views of the working man Was he just a good Christian dispensing culture or was he deeply moved and concerned with the ordinary man's estate ? We do not know Maxwell was born the year before Russell's Reform Bill in 1832 and died a few years after the Acts passed by Gladstone and Disraeli to give trades unions some status It was only in 1870 that Forster's Education Act provided primary education for all These events were the background to Maxwell's life, but it does not appear that he was affected by them in any profound way

We are told that Maxwell was a reader of the works of Dryden, Swift and Butler So far so good, but he lived in one of the richest periods of English literature Shelley, Keats, Lamb and Scott were not long dead, and Dickens, Tennyson, Thackeray, Mathew Arnold, Macaulay, Mrs Gaskell, Trollope, George Eliot and Meredith were all writing, and many were at the height of their powers in his lifetime Maxwell has been described as a civilized man, in a narrow sense, yes I would say rather that he was a man of concentrated scientific genius, devoted to his home and family and little influenced by, or interested in, the comfortable broad middle-class culture of his day This picture may be unjust in that his biographers have completely failed to paint in the general background to his life We do not particularly wish to know what a great scientist eats for his breakfast but we would like to know something of his relationship to the times in which he lived Maxwell's culture was in truth a spiritual one, not a material one like Kelvin's, and it is for this reason perhaps that we have such an imperfect picture of Maxwell the man

In the preparation of the lecture on which this article is based I have of course, made much use of Maxwell's collected works and of the well-known *Life* by Campbell and Garnett In addition to these and other standard sources, I am particularly indebted to Dr I B Hopley's University of London thesis (1956) I also thank Dr G R Wilkinson of King's College, London, for his help in searching what remain of the King's College archives and for much valuable discussion

OBITUARIES

Sir William Mitchell, K C M.G

Sir William Mitchell, emeritus professor of philosophy, former vice-chancellor and chancellor of the University of Adelaide, died in Adelaide on June 24 at the age of 101

Sir William was born at Inveravon, Banffshire, Scotland, in March 1861 He received his early education at Elgin and later entered the University of Edinburgh, where he graduated M A and D Sc in philosophy

His first appointment was as lecturer in ethics in the University of Edinburgh, and from there he went to University College, London, as lecturer in education Later, he was appointed examiner in philosophy at Edinburgh and in the theory of education at the University of Cambridge

In 1894 he joined the University of Adelaide as Hughes professor of English language and literature and mental and moral philosophy From the beginning of his professorship, he took an active part in the government of the University, and in 1896 was elected to its Council Sir William became vice-chancellor in 1916 and held this office continuously until 1942 In 1927, he was created a Knight Commander of the Order of St Michael and St George On the death of Sir George Murray in 1942, he was elected chancellor of the University He relinquished that office on January 31, 1948

Sir William was counted among the distinguished philosophers of his day In 1924, he was invited to deliver the Gifford Lectures in the University of Aberdeen, and in 1934 he delivered the philosophical address of the year to the British Academy But perhaps his greatest contribution to scholarship was his work as a teacher He had a singular and powerful gift for enabling those whom he taught to discover where their deepest interests lay and to develop themselves with confidence and vigour

He was also remarkable for the natural and most acceptable leadership which he exercised throughout his long service as a member of the governing body and as vice-chancellor of the University of Adelaide He bore his years lightly, and his spare, vigorous figure was often to be seen in the University after he had passed his eightieth birthday Indeed, he enjoyed remarkable health and mental vigour until a serious illness beset him in 1958 From this he recovered, but was thereafter much restricted in his activities He kept until the end of his long life a graciousness and serenity which made and preserved for him many friends

He is survived by a daughter, Mrs J R Thomson, and a son, Sir Mark Mitchell, professor of biochemistry and general physiology and deputy vice-chancellor of the University of Adelaide H B Basten

Prof Granville Poole

Prof Granville Poole, emeritus professor of mining engineering in King's College, Newcastle upon Tyne (University of Durham), died on May 26, aged seventy-six

Prof Poole was a man of outstanding character who commanded respect not only by his ability as a mining engineer of wide experience, but also by his sincerity and deep interest in all matters relating to safety in mines He was a tall, straight, distinguished man, identified by his wing collar and bow tie, and as we know him, with a gentle manner and a commanding personality.

His students at Armstrong College (later King's College), Newcastle upon Tyne, where he held the Milburn chair of mining engineering from 1923 until 1951, will always remember his custom of sitting with them in the front row of the lecture theatre and illustrating his lectures by recalling incidents in his earlier career in the Inspectorate and at the Ministry of Mines

His experience was unique in the coal-mining industry in that he was associated, as private secretary to H M Chief Inspector of Mines during 1911–13, with the passing of the 1911 Coal Mines Act and again in 1954 as an adviser to the National Union of Mineworkers Parliamentary Committee when the 1954 Coal Mines Act was being formulated.

His career belies present-day beliefs, in that as a young graduate from the University of Birmingham he was given responsibility at the early age of twenty-four as one of H M Inspectors of Mines in 1909 He gained promotion in the Inspectorate to senior rank in 1917 His appointment to the chair of mining at the University of Leeds in 1919 when only thirty-three must also make him one of the youngest mining engineers of his era ever to hold a chair He moved to Newcastle upon Tyne and the Milburn chair of mining at Armstrong College in 1923, following the retirement of Prof Henry Louis

It was at Armstrong College, which became King's College in 1929, that Prof Poole was responsible for securing the funds for building the present Department of Mining Engineering He was a justifiably proud and happy man in 1929 when the Prince of Wales formally opened the new building This Mining Engineering Department was unique and well equipped and established a permanent building in a College which had taught mining engineering subjects as long ago as 1865

Prof Poole was an active member of the Institution of Mining Engineers from 1908, first as a member of the South Staffordshire Institute and later of the North of England Institute of Mining and Mechanical Engineers He was a member of Council from 1935, a vice-president from 1945 and president of the North of England Institute during 1950–52 It was particularly appropriate and was a great personal honour and pleasure that he was the president during the Centenary Celebrations of this Institute in 1952

He was widely consulted in mining matters and retained his links with the Staffordshire Coalfield as a consultant to the Shelton Iron and Steel Co

Prof Poole will, however, always be remembered by his students as a man who set the highest example in integrity and loyalty and for his continual encouragement to those who passed from the University into the industry E L J Potts

NEWS and VIEWS

Physics at Chelsea College of Science and Technology :

Dr. W H George

Dr W H George, who has been head of the Department of Physics in Chelsea College of Science and Technology since 1938, is retiring at the end of the present session Dr George was Royal Society Sorby Research Fellow in the University of Sheffield, then lecturer in the University of Southampton before his appointment at Chelsea, his research has been mainly in X-ray crystallography and acoustics He has greatly stimulated the provision of post-graduate degree courses, particularly since the War

Dr K. W Keohane

Dr K W. Keohane has been appointed to succeed Dr George He served during the War in the Radar Branch of the Royal Air Force and graduated with first-class honours in physics in the University of Bristol in 1947 After work on reflecting microscopy with C. R Burch, Dr. Keohane's interest turned to biophysics and he afterwards joined Prof J M Yoffey, first as a research associate and then as lecturer He was awarded a Ph D for the application of absorption spectrometry to single cells and is well known for his work in collaboration with W K Metcalf on the physical properties of erythrocytes and lymphocytes He was appointed reader in physics at Chelsea in 1959 and has developed research in biophysics at the College, particularly in the field of electrical properties of cell membranes

Geology at Liverpool :

Prof W S. Pitcher

Dr W S Pitcher, reader in geology in King's College, London, has been appointed to the George Herdman chair of geology in the University of Liverpool, rendered vacant by the resignation of Prof R M Shackleton, who has been appointed to the second chair in the Department of Geology in the University of Leeds (*Nature*, 193, 1233, 1962) Dr Pitcher, who is forty-three years of age, was awarded the degree of B Sc at the University of London in 1947, and the degree of Ph D in 1951 He served with H M Forces during the Second World War and on demobilization he became a student at the Chelsea College of Science and Technology In 1947 he was appointed demonstrator at the Imperial College of Science and Technology, London, afterwards being promoted assistant lecturer, and later lecturer, and in 1955 he was appointed reader in geology in King's College, London In 1948 he served as assistant secretary to the International Geological Congress Dr Pitcher's special field of research has been the geology of the County of Donegal, where he has made a special study of the mode of emplacement of the Caledonian granites In recognition of his researches he was awarded the Lyell Fund of the Geological Society of London in 1956 His other interests are the ring complexes of Northern Nigeria and certain aspects of the Tertiary geology of south-east England

Personal Chair of Biochemistry at Leeds :

Prof S Dagley

Dr S Dagley was awarded an open scholarship in natural science at Keble College, Oxford, in 1934 and graduated in 1937 with honours in chemistry He obtained the degree of B Sc in 1938 for a thesis on "The Chemical Kinetics of Bacterial Growth" under the supervision of Sir Cyril Hinshelwood During the Second World War he was employed as a chemist in the Ministry of Supply, and in 1944 he was appointed chemist in charge at the Royal Ordnance Factory, Pembrey, Carmarthenshire From 1945 until 1947 he was a lecturer in chemistry at the Sir John Cass College, Aldgate, where he continued his research work on the kinetics of bacterial growth In 1948 he was awarded the degree of M Sc at the University of London and in 1956 the degree of D Sc Dr Dagley was appointed a lecturer in the Department of Biochemistry in the University of Leeds in 1947, and in 1952 the title of reader in physiochemical aspects of biochemistry was conferred on him His research at Leeds has been concerned chiefly with the biochemistry of bacteria His research team has studied new ways by which bacteria open the benzene nucleus, the reactions by which they synthesize their cell constituents from simple chemicals and also the effect of antibiotics on certain structures inside the bacterial cell He has contributed to symposia organized by the Faraday Society, the Society for General Microbiology and the Chemical Society

New Research Synchrotron for Northern England

Lord Hailsham, Lord President of the Council and Minister for Science, has announced the approval of the proposal of the National Institute for Research in Nuclear Science to establish a second laboratory, which will contain a 4-GeV electron synchrotron The new laboratory will be in the north of England and will be particularly associated with the Universities of Liverpool, Manchester and Glasgow, but scientists from other universities and institutions, as well as scientists on the Institute's own staff, will also carry out research there The estimated capital cost of the laboratory and the synchrotron is about £3½ million The first director of the laboratory will be Prof A W Merrison, who is being released from administrative responsibilities at the University of Liverpool for a period of five years so that he may take up this post (for details of Prof Merrison's career see *Nature*, 185, 284, 1960) Like *Nimrod* at Harwell, the new synchrotron will be used for research into the nature of the fundamental particles of matter, but as it will produce high-energy electrons rather than high-energy protons, the experiments carried out will be quite different The new accelerator will also be complementary to *Nimrod* as regards the universities to which it will be conveniently accessible The Physics Departments at Liverpool, Manchester and Glasgow are particularly interested in this field of physics The 4-GeV electron synchrotron was selected after a careful study carried out by the National Institute for Research in Nuclear Science in 1960 and the first half of 1961 The proposal to build it was announced in the Institute's annual report for 1960–61 A similar accelerator is in operation jointly by Harvard and the Massachusetts Institute of Technology in the United States, and two others are under construction, at Hamburg and in the U S S R

The Biohistorical Institute of the University of Utrecht

The new Biohistorical Institute of the University of Utrecht was formally dedicated on May 30 Among the speakers were Prof J Lanjouw (director of the Utrecht Institute for Systematic Botany), who made the original plans for the Institute, and Prof G A Lindeboom (Free University of Amsterdam), who spoke on the importance of the humanistic aspects of biology and early medicine in general Prof F Verdoorn, the Institute's director, outlined the concept of biohistory, that is, all areas where the pure and applied life sciences (including early medicine), on one hand, and cultural history, literary and art history, and sundry other branches of the humanities, on the other, overlap He also described how an effort is being made to develop the Utrecht Biohistorical Institute simultaneously as a research, as an educational, as a documentation and (in conjunction with the International Biohistorical Bureau) as an international institution In the annals of the University of Utrecht, the Biohistorical Institute is unique by being housed in one of the oldest University buildings (which served for more than two centuries as the official residence of the director of the *Hortus Academicus*), while the contents (the former *Chronica Botanica* Library and Archives) were chiefly built up in the United States

As to the organization of the Biohistorical Institute, there are three divisions of a primary nature, each constituting a 'triple unity' and consisting of (*a*) books, (*b*) extensive card indexes of the relevant world literature, and (*c*) supplementary archivalia (such as engravings, autographs, manuscripts, portraits), the historical and bibliographical, the biographical, and the topographical division Other units are the literary and art historical division, the reading and periodicals room, etc In connexion with the dedication of the Utrecht Biohistorical Institute, a number of selective exhibits from the Institute's own holdings were organized, including (1) garden history and landscape architecture in the past and present, (2) Nature prints, (3) works by and about Carolus Linnaeus, mainly of a general biological and medical interest, (4) literature and art in biology and early medicine, (5) works edited by Fr and J G Verdoorn (1935–62), (6) recent acquisitions of the Institute's Library, (7) *Leeuwenhoeckiana* (a survey of the work of the Leeuwenhoek Commission of the Royal Netherlands Academy of Sciences, which has its headquarters at the Utrecht Biohistorical Institute)

The British National Committee on Surface Active Agents

The British National Committee on Surface Active Agents has recently been inaugurated Membership is open to all *bona fide* manufacturers of surface active agents in the United Kingdom The Committee has been formed primarily to foster British interests in the field of surface activity on an international basis Its aims and objects have been defined as (*a*) to seek membership of the Comité International de la Détergence, (*b*) to consider all questions of a technical character relating to the work of the Comité International de la Détergence, its technical Commissions and International Standards Organization Committees on Surface Activity, (*c*) to maintain liaison with organizations and individuals in the United Kingdom having interests in the field of surface activity, (*d*) to co-ordinate participation by the United Kingdom in International Congresses on Detergency The seventeen founder members include all the major manufacturers of surface active agents in the United Kingdom The officers are Mr R C. Tarring, Shell Chemical Co , Ltd (president), Dr. A F Kertess, Associated Chemical Companies, Ltd. (treasurer), Mr H W Vallender (secretary-general). Further information concerning membership, etc , can be obtained from the Secretary-General at 86 Strand, London, W C 2

John Alexander Reina Newlands

Dr F W Gibbs, of the Royal Institute of Chemistry, has recently provided the editor of *Nature* with the following information "John Alexander Reina Newlands, propounder of the 'Law of Octaves', died on July 29, 1898, aged sixty (according to 'W S ', *J Soc Chem Indust*, 743, 1898) or sixty-one ('W A T ', *Nature*, 58, 395, 1898) The year of his birth has thus been stated by some as 1838 and by others as 1837 Comprehensive registration of births began in the summer of 1837, and a search at Somerset House has revealed the existence of a birth certificate It transpires that Newlands was born at the family address, 19 West Square, Southwark, on November 26, 1837 The birth was registered on December 26 (Bank holidays were introduced by the Act of 1871) His father, William Newlands, was a Presbyterian minister and his mother was formerly Mary Sarah Reina"

Radiation and Health

In October 1960, the International Atomic Energy Agency and the World Health Organization sponsored a scientific meeting on the diagnosis and treatment of acute radiation injury (*Diagnosis and Treatment of Acute Radiation Injury* Pp 425 Geneva World Health Organization, 1961 £2) The proceedings were reviewed together with other recent developments in radiation medicine in a special number of the *WHO Chronicle* published in December 1961, and have recently been reprinted as a brochure (*Radiation and Health* Pp. 44 Geneva World Health Organization, 1962 1*s* 9*d*) In addition to three general sections on radiation protection, there are short reviews on health hazards from nuclear-powered merchant ships, accidental radiation injury, management of radiation casualties, therapeutic uses of radiation injury, and statistics in genetic and radiation studies

Radioactivity in Diet

The seventh report of the Agricultural Research Council's Radiobiological Laboratory (H M S O , *ARCL* 7) records measurements carried out between December 1961 and April 1962 The resumption of nuclear weapons trials in September 1961 lends particular interest to this interim report Iodine-131 reached a maximum concentration in milk about the end of October 1961 (see *ARCL* 6) and thereafter fell rapidly to levels below the limits of detection by the beginning of 1962 The country-wide average in milk over the period of 32 weeks following the resumption of nuclear weapon trials was 17 per cent of that which would give rise to the annual average of 130 picocuries per litre which the Medical Research Council has stated would not cause the acceptable radiation dose to be exceeded for any age group of the population The strontium-90 levels in milk rose by about 20 per cent between October and December 1961 as compared with the corresponding levels the previous year although the country-wide figure calculated over the whole year was a little lower than that for 1960. These figures are reassuring, but the full effects of the weapons trials on strontium-90 levels in milk are not expected to be apparent until the results for the summer of 1962 are available. For the average mixed diet of the whole population, the strontium-90 level during 1961 was about 6.1 picocuries of strontium-90 per gram of calcium. This value is similar to that of 1960 and lower than that of 1959.

The Lace Research Association

The thirteenth annual report of the Lace Research Association covers the year 1961 (Pp. 35. Bilborough, Nottingham: The Lace Research Association, 1962). In the account of the progress of research, it is noted that production of cellular cotton blankets for hospital use has now reached an advanced stage of development, and it is considered that a similar blanket structure made from an acrylic yarn might be more suitable for the domestic market. A successful technique has been devised for producing tubular nets on the furnishings machine, while the problem of winding an increased length of usable yarn into the Leavers machine, in which the brass bobbins carrying the binding thread of the lace structure are spread between 8 and 30 per inch, is being tackled. This is being done by investigating the use of special nylon yarns of fine count and extra strength, by radically improving the machinery for winding the yarn into the bobbins and by examining the processes of heating and pressing the bobbins after winding. The new 'Lacra' bobbin winders have fulfilled in production all the claims made for them, fundamental work on the heating and pressing of brass bobbins continues. The new beam thread-break indicator has also given satisfactory results on a production scale. The Association has assessed the potentialities of the new high-speed lace machine designed by Dr. McGallion and Prof. Pope of the University of Nottingham. Two of the major projects of the year were concerned with the mechanical removal of floats from lace and the treatment of lace to give low flammability.

The Rubber Research Institute of Ceylon

The rubber industry of Ceylon, though small compared with that of Malaya, is nevertheless of vital importance to the country's economy, as it was to Great Britain and her allies during a critical phase of the Second World War. It is interesting to recall that it was in Ceylon in 1876 that the plantation industry was born—from plants nurtured at Kew—though it was not until the present century that plantation rubber began to oust native Brazilian rubber as the primary commodity of commerce. The place of science in the subsequent development of the industry is recognized in a booklet issued on the occasion of the fiftieth anniversary of the foundation of the Rubber Research Scheme—the forerunner of the present Rubber Research Institute of Ceylon—to which leading members of the Government and of the industry have contributed (*Rubber Research Institute of Ceylon: Golden Jubilee, 1910–1960.* Pp. xviii+14. Dartonfield, Agalawatta: Rubber Research Institute of Ceylon, 1961). In the face of intense competition from the synthetics, the plantation industry depends for its survival on the reduction of costs and improvement of quality which can only be brought about by the fullest exploitation of scientific knowledge and scientific methods. Factors of major importance are the replacement of older and inefficient trees with newly developed high-yielding types, the effective control of disease, and good husbandry and estate management. In all these aspects the Institute's scientific and advisory staff, working within a frame-work of Government assistance, has played an indispensable part, particularly in relation to the small-holders.

Research into Urban 'Decay'

The June *Newsletter* of the Manchester Joint Research Council Technical Information Centre, besides notes on some inquiries handled in May, includes a note by Mr. F. Medhurst, director of the Research Group of the North West Civic Trust, on research into urban 'decay', which touches on some aspects of his task. The Research Group, which hopes to discover the obstacles to improving the general environment of the mixed areas around city centres, will study land and property values, investment-levels, public transport services, changes in land uses and obsolescence factors for clues to the causes of urban decay. The study is planned to continue over three years, and an endeavour will be made actively to improve a selected area as an experiment in methods and techniques. The Research Group will welcome the suggestions and co-operation of any who are interested in the problem.

Ancient Monuments Boards

The eighth annual reports of the Ancient Monuments Boards for England, Scotland and Wales contain much of interest in addition to the usual formal information (Pp. 19+4 plates. London: H.M.S.O., 1962. 2*s*. net). The difficulties encountered in draining the land at Stonehenge are discussed, but as yet no solution has been found. It is stressed that it is desirable to retain the turf which provides such an admirable setting for the stones. It is now recommended to the Minister that, because of irresponsible behaviour, there should be an absolute ban on the solstice ceremonies on Midsummer Eve. It is proposed that the long barrow known as Wayland's Smithy in Berkshire should be examined by modern techniques, and it is reported that the Hull Museum is willing to take over and re-display the important pavement at the Roman villa at Rudstone. It is hoped that means will be found to preserve the somewhat unusual seventeenth century water garden at Westbury-on-Severn, Gloucestershire, and the Board welcomes the action of the Council for British Archæology in their endeavours to preserve and record early industrial buildings. Reference is made to emergency excavations including that of the Saxon and medieval palace at Cheddar, and recommendations for scheduling are made in respect of 340 monuments. The report for Scotland refers to the continual quarrying at Traprain Law and the great interest of the Orkney monuments. The Board in Wales have recommended the scheduling of a further 31 monuments, several of which have only been discovered by aerial photography.

The Museums Association

The sixty-eighth annual conference of the Museums Association was held in London and Brussels during June 25–29 under the presidency of Dr. Mary Woodall. The presidential address and the annual general meeting were held in London, and the delegates then travelled to Brussels for the rest of the meeting. In her address, Dr. Mary Woodall dealt with present-day matters in the business of the Association and made especial reference to the importance of the forthcoming report which is to be presented to H M Government by the Standing Commission on Museums and Art Galleries It is anticipated that the report will be available in the late autumn and that it will be intimately associated with the recently established Area Museum Councils Reference was also made to the continued generosity and interest of the Carnegie U K Trust, new regulations for the training of curators and technicians, and the new format of the *Museums Journal* Diplomas and technical certificates were presented to the successful candidates in the recent examinations, and Dr D A Allan, Sir George Dyson and Dr F J North were elected to Honorary Fellowship Alderman H Barks and Dr Barnett Stross were elected as institutional councillors, and Miss Anne Buck, Mr A A Cumming, Mr T H Scrutton and Mr H R Singleton were elected as professional councillors Sir Trenchard Cox was elected president for 1962–63, and the invitation of the University and City to hold the 1963 meeting at Newcastle upon Tyne at the end of July was accepted with thanks In Belgium, visits were made to the museums and art galleries in Antwerp, Limburg, Brussels, Tornai, Halle, Ghent, Bruges and Liège Opportunity was also taken to visit various historical buildings in the same places The annual dinner of the Association was held at the Hotel Metropole in Brussels

The Institute of Applied Science of Victoria

THE report of activities of the Institute of Applied Science of Victoria for the year ended June 30, 1961, comprises the report of the Trustees and the report of the director, Dr C M Focker, both of which refer to a donation for the establishment of a planetarium (Pp. 24 Melbourne Institute of Applied Science of Victoria. 1962) The Radiocarbon Dating Laboratory was opened in May 1961, some seven age determinations have been completed and the equipment has functioned well Completion of the new wing offered a major increase in display and working space and visitors are expected to exceed 400,000 annually when the planetarium is operating Long-term displays noted by the director include some on decimal currency, Edwin Land's sodium mirror, solar batteries, radioactivity and the Trevithick high-pressure steam engine

Microdoc

Microdoc, the journal of the Council on Microphotography and Document Reproduction, the first number of which is commendably concise and to the point, is intended to keep members abreast of progress and events, as well as provide a forum for the research article, the review, the query and the complaint (1, No 1 Edited by Mark Patterson Pp 16 London The Library Association, 1962 Subscription (non-members) 30*s* per annum) In this number, Mr L L Ardern writes briefly on the opaque versus the translucent screen and on the Dagmer Super Reader as well as contributing a review of Mr G U Davison's *Microtext Review of Progress in 1960* Mr E F Patterson describes the new 'V C Executive Reader', and Mr L Corbett the 'AO Micro Opaque Reader', and Dr L A Sayce's address at the meeting in October 1960 which voted in favour of establishing an advisory council on microphotography and document reproduction is reproduced Altogether, the first issue of this new venture gives a very pleasing impression of purpose and performance

British Chemicals and their Manufacturers

THE Association of British Chemical Manufacturers has recently issued the 1962 Supplement to the 1961 edition of the Association's Directory, *British Chemicals and their Manufacturers* (see *Nature*, 192, 1025, 1961) The Directory is published at two-yearly intervals, and during this period there are inevitably many changes and additions in the list of products manufactured This Supplement provides full details of these changes and will ensure that users of the 1961 Directory have up-to-date information regarding manufacturers of chemicals in the United Kingdom In order to assist users, a new lay-out and format have been adopted so that the information contained therein may be incorporated in the main Directory if so desired As in the case of the Directory, the Supplement is available gratis to all firms and persons interested in the purchase of chemicals and allied products (Pp 29 London Association of British Chemical Manufacturers, 1962)

Guide for Families of those in Mental Hospitals

To most people the realization that a relative or close friend is mentally ill and needs hospital treatment comes as a grief and a shock To help people faced with this situation, the National Association for Mental Health has produced a booklet of simple explanation and practical advice (price 2*s*) It replaces a publication issued some years ago before the new Mental Health Act made it possible for mental illness to be treated with as little formality in most cases as physical illness The booklet explains what kinds of help are available to patients and their families from the family doctor to the staffs of clinics and hospitals and workers in the local authority services. A brief summary of legal provisions is added as an appendix, with a glossary of some terms used in connexion with mental illness, a reading list and a list of local voluntary mental health associations existing in different areas

Chemistry and Mental Disease

A SYMPOSIUM on "Chemistry and Mental Disease", arranged by the Royal Institute of Chemistry, the Chemical Society and the Society of Chemical Industry, will be held in the University of Manchester on September 26 The programme will include biochemical processes in relation to mental disease (Dr A Todrick), inborn metabolic errors and mental disease (Dr L I Woolf), pharmacological assessment of psychotropic activity (Dr M W Parkes), tranquillizers—structure and activity relationships (Dr A F Crowther), psychostimulants—structure and activity (Dr E H P Young), use of modern drugs in psychiatric practice (Dr. F A Jenner) Further information can be obtained from Mr H H Armstrong, Science Department, Stockport College for Further Education, Wellington Road South, Stockport

The Jane Coffin Childs Memorial Fund for Medical Research

THE Jane Coffin Childs Memorial Fund for Medical Research has recently announced that during the past year twenty-eight grants-in-aid and twenty-three postdoctoral fellowships were awarded, totalling 382,459 85 dollars The Fund supports investigations in the fundamental aspects of neoplastic growth, and awards postdoctoral fellowships to candidates of outstanding potential in the same field Applications for grants-in-aid are reviewed by the Board of

Scientific Advisers and the Board of Managers of the Fund three times a year, in the autumn, winter and spring Final dates for receipt of applications are September 1, November 1 and March 1 Applications for fellowships are reviewed at the winter meeting of the Fund, the final date for applications being October 1 of each year Grants-in-aid and fellowships are not restricted to United States subjects Information can be obtained from the Office of the Director, 333 Cedar Street, New Haven 11, Connecticut

University News.

Edinburgh

THE following grants have been received by the University of Edinburgh £69,150 from the Nuffield Foundation, in support of the fibroblast research programme being carried out in the Department of Zoology, 5,000 dollars from the Rockefeller Foundation, for the expenses of a symposium on "Genetics of Colonizing Species" in the Department of Animal Genetics, £950 from the Department of Scientific and Industrial Research, for a research project on the rearing of a rare spawning of 'non-pigmented' toad eggs in the Department of Zoology, £2,500 from the United Kingdom Atomic Energy Authority, for a two-year investigation on unsupported oxide layers to be carried out in the Department of Chemistry, £50,000 from the Wellcome Trust for the cost of erecting a building to accommodate the new Medical Research Council Research Group on Epigenetics in the Department of Animal Genetics

London

THE following appointments have been announced Dr Roland Hill, lecturer in animal nutrition at the University of Reading, to the readership in animal husbandry and hygiene tenable at the Royal Veterinary College, Dr A A Johnson, lecturer at the Imperial College of Science and Technology, to the readership in physical metallurgy tenable at that College. The title of reader in civil engineering analysis has been conferred on Dr R E Gibson in respect of his post at the Imperial College of Science and Technology

The title of professor emeritus has been conferred on the following Prof J W S Blacklock (professor of pathology, St Bartholomew's Hospital Medical College), Prof J H Birkinshaw (professor of biochemistry, London School of Hygiene and Tropical Medicine), Prof G P Crowden (professor of applied physiology, London School of Hygiene and Tropical Medicine), Prof J McCunn (professor of veterinary anatomy, Royal Veterinary College), Prof L A Reid (professor of philosophy of education, Institute of Education), Prof W R Spurrell (professor of physiology, Guy's Hospital Medical School) The title of professor of theoretical mechanics has been conferred on Dr R S Scorer, in respect of his post at the Imperial College of Science and Technology and that of reader in psychopharmacology on Dr Hannah Steinberg, in respect of her post at University College

Nottingham

THE title of reader has been conferred on Dr C A M King (geography), Dr T J King (organic chemistry), Dr H Fessler (mechanical engineering)

Announcements

MR B D HANKIN has been appointed director of the City and Guilds of London Institute with effect from October 1 Mr. Hankin is at present a principal scientific officer with the Ministry of Transport As director, he fills a vacancy created by the Institute in its reorganization in which Major-General C. Lloyd was raised to the status of director-general

THE next award of the Meldola Medal, the gift of the Society of Maccabæans, will be made early in 1963 to the chemist who, being a British subject and less than thirty years of age on December 31, 1962, shows the most promise as indicated by his or her published chemical work brought to the notice of the Council of the Royal Institute of Chemistry before December 31, 1962 Further information can be obtained from the Secretary, the Royal Institute of Chemistry, 30 Russell Square, London, W C 1, the envelope being marked 'Meldola Medal'

A SYMPOSIUM on "Measurements in Hydrology", organized by the Water Research Association, will be held in the University of Reading during September 18–20 Further information can be obtained from the Water Research Association, Medmenham, Marlow, Bucks.

THE sixth International Congress on High-Speed Photography will be held in Scheveningen during September 17–22 Further information can be obtained from Dr J G A de Graaf, Secretariat of the Sixth International Congress on High-Speed Photography, 14 Burgemeester de Monchyplein, The Hague

AN informal discussion on "Nuclear Chemistry, Fission and other Low Energy Nuclear Processes" will be held in the University of Oxford during September 18–20 Further information can be obtained from Mr G N Walton, Scientific Administration Office, Atomic Energy Research Establishment, Harwell, Didcot, Berks

A SYMPOSIUM on the latest developments and techniques in auto-analysis and also the introduction of several new devices, organized by Technicon Instruments, Ltd , of Chertsey, will be held at the National Film Theatre during September 17–18 Further information can be obtained from Mr James Evans, Technicon Instruments, Ltd , Hanworth Lane, Chertsey

A SUMMER school on "Interaction between Atmosphere and Ocean", supported by the Scientific Affairs Division of the North Atlantic Treaty Organization, will be held in London during September 3–14 Further information can be obtained from Mr H Charnock, Viale San Bartolomeo 92, La Spezia, Italy

THE first European malacological congress, organized by a joint committee of the Conchological Society of Great Britain and Ireland and the Malacological Society of London, will be held in London during September 17–21 Further information can be obtained from Mr J F Peake, Department of Zoology, British Museum (Natural History), Cromwell Road, London, S W 7

AN international course on "Chromatographic Methods in Lipid Research", sponsored by the Institute of Pharmacology and Therapy of the University of Milan and the Italian Society for the Study of Oils and Fats, will be held in the University of Milan during September 17–29 Further information can be obtained from Prof R Paoletti, Institute of Pharmacology, University of Milan, Via Andrea del Sarto 21, Milan

GOVERNMENT EXPENDITURE ON SCIENTIFIC RESEARCH, 1961

THE report of the Council for Scientific and Industrial Research for the year 1961*, which this year is mainly concerned with assisting industry to apply the results of research, records gross expenditure in the year ended March 31, 1961, of £14,467,278, compared with £12,008,536 in the previous year, and reduced to £12,759,180 by various receipts from industry and other sources for services rendered, of which £607,910 was from other Government departments and £819,255 from industry, £249,325 being received by the National Physical Laboratory, the net increase on 1960 was £2,416,489. Grants to students amounted to £1,105,415 (£870,289 in 1960), and 1,102 new research studentships, with 1,607 continuing from previous years, brought the total current on October 1, 1961, to 2,709. Besides these, there were 339 advanced course studentships, 66 first year studentships and 88 research fellowships, these figures include 154 NATO studentships and 35 fellowships.

Of the research students, 356 were in biology and biochemistry, 190 in chemical engineering and metallurgy, 833 in chemistry, 99 in electrical engineering and 161 in other engineering, 173 in geology, 46 in the human sciences, 261 in mathematics and 590 in physics. The advanced course studentships were distributed mainly in physics (70), mathematics (63), engineering (other than electrical) 53, with 35 in chemical engineering and metallurgy, 32 in geology, and 30 in the human sciences. All the first year studentships were in chemistry, and of the research fellows, as in previous years, chemistry (30), physics (27) and biology and biochemistry (18) claimed the most.

Grants for special researches totalled 696, of which 332 were new, amounting to £7,937,910 in the year ended March 31, 1961, and of this total 72 in nuclear physics amounted to £3,196,947, only in technology (113 grants totalling £804,593), chemistry (141, £771,801) and low-temperatures and solid-state physics (81, £710,117) did the total exceed £500,000, though this figure was approached by 100 grants in biology (£491,569) and 66 in geology and geophysics (£494,514), 31 grants in space research totalled £395,300. There were 41 grants, totalling £316,910, in the human sciences. During the academic year 1960–61, the Research Grants Committee considered 447 applications for grants, other than those for very expensive capital projects, with a total value of £3,156,000, compared with 422 valued at £3,444,000 in the previous year, and made 362 grants with a total value of £1,961,000, compared with 315 amounting to £1,712,000 in 1959–60. In addition, a capital grant of £803,516 was made to the University of Oxford to establish a nuclear structure group under Prof. D. H. Wilkinson, and grants totalling £167,355 for the maintenance of large nuclear physics machines at the Universities of Birmingham, Cambridge, Glasgow, Liverpool and Oxford, and for completion of the linear accelerator at Manchester.

With the exception of fire research, which decreased to £156,130 from £158,441 in 1959–60, and radio research, which at £239,957 was practically unchanged, the increased expenditure was distributed fairly generally over all branches of the Department's work. The major increases are in the expenditure of the National Physical Laboratory (£1,787,542 gross, £1,438,776 in 1959–60), Road Research Laboratory (£872,805, £718,058), National Engineering Laboratory (£811,164, £686,156), Warren Spring Laboratory (£453,985, £402,854), Building Research Laboratory (£785,413; £656,975), Geological Survey and Museum (£586,640, £490,014), and the National Chemical Laboratory (£384,073, £316,080). Expenditure by the Government Chemist now under the Department's vote increased from £290,237 to £460,257. Expenditure on headquarters administration also increased, from £623,206 to £758,126, and annual grants to research associations from £1,761,368 to £1,849,572, with £31,677 in special grants. Grants for special researches amounted to £1,495,469, compared with £912,944 the previous year, while contributions to the European Organization for Nuclear Research rose to £1,330,000 and to NATO scientific schemes to £122,534. There was a record net increase in staff of 544, bringing the total to 6,224, and the 52 research associations have a total expenditure of more than £8 million.

NITROGEN HETEROCYCLIC CHEMISTRY

IN 1955, a symposium on heterocyclic chemistry, organized by the Chemical Society, was held at the University of Exeter. Its success was noted by the publication of the papers presented there[1]. A second related symposium was held in the Australian National University at Canberra in 1957. It attracted equal interest, though for geographical reasons largely from a different audience, once again the papers and discussions are accessible[2].

It is a tribute to the importance of the subject, to its rapid development, and to the active interest of teachers and workers in the field, that the Hatfield College of Technology, with the support of the Chemical Society, was able to arrange, in attractive quarters and surroundings, during May 10–11, a third, equally successful, symposium. The title was "Nitrogen Heterocyclic Chemistry". A wide field of chemistry was covered in nine papers delivered in four sessions, one of which was chaired by Prof. A. Albert, of the Australian National University, who played an active part in each of the two previous symposia.

The symposium was opened by Prof. W. Baker. A remarkable standard of material and presentation was set in the first paper, by Dr. J. W. Cornforth of the National Institute for Medical Research. He described an elegant and imaginative approach to the synthesis of vitamin B_{12}, which is of interest as an important factor in metabolism and as a coenzyme in some remarkable rearrangements of carbon chains *in vivo* Considered as a heterocyclic compound it poses unusual problems, a macrocyclic ring containing nine asymmetric carbon atoms and a combination of conjugated C=C and C=N bonds The route described involved separate syntheses of structures, each containing some of the asymmetric centres, in such a way that subsequent combination should be possible Some novel methods had to be devised One of them, a synthesis of 1,3-diketones, depends on the chemical reduction of pyridinium enol betaines, and an interesting discussion on this point developed at the conclusion of the lecture

In the following paper, Prof P B D de la Mare of Bedford College (University of London) discussed electrophilic substitution in nitrogen heterocycles by reference to analogies from the chemistry of non-heterocyclic systems It was pointed out that electrophilic attack on compounds containing unsaturated nitrogen often occurs at nitrogen rather than at carbon The fact that the different species thus produced may have different relative reactivities in subsequent steps was illustrated by discussion of the extreme cases of quinoline-N-oxide, the quinolinium cation, and the N-nitroquinolinium cation, and of derivatives of aniline and carbazole. The importance of the identity of any nucleophile which may participate in an addition-elimination sequence, and of details of the structure of any intermediate thus produced, was mentioned in connexion with the similarities and differences between the halogenation of phenanthrene, naphthalene and quinoline It was observed that, despite a recent publication taking a contrary view[3], the quinoline molecule itself is not known to be attacked electrophilically at carbon in any experiments yet described In the discussion which followed, misconceptions concerning the ease of addition of strong acids to C=C, C=O, C=N and N=N bonds were mentioned, it seems important to remember that, even when such additions are reversible and the consequent equilibria lie largely towards the starting materials, the adducts may, when their chemistry is appropriate, be important intermediates leading to further reactions

The third paper, by Prof Wilson Baker of the University of Bristol, described meso-ionic compounds as a varied group of nitrogen-containing heterocycles having six π-electrons associated usually with a five-membered ring In general, they are highly polar, and show the characteristic stability of aromatic compounds They are distinguished by the fact that they cannot be represented satisfactorily by a single canonical structure, but only as a resonance hybrid of a number of zwitterionic or tetrapolar canonical forms A review was given of their discovery and of the general chemistry of the various different types that have been recognized The discussion centred largely round the question of definition, terminology, and classification

In the fourth paper, on the synthesis of heterocyclic compounds by extrusion of sulphur, Dr J D Loudon of the University of Glasgow described ring-contractions in which extrusion of sulphur yields naphthalenes from benzo[*d*]thiepins, phenanthrenes from dibenzo[*b,f*]thiepins, phenanthridines from dibenzo-[*b,f*]-1,4-thiazepines, and benzoquinolizinium salts from pyrido[2,1-*b*]benzo[*f*]-1,3-thiazepinium salts The influence of the polar effects of substituents was discussed, and it was pointed out that the probable reaction course involves bond rearrangement to an episulphide, followed by extrusion of sulphur in harmony with the olefine-forming tendencies of episulphides and episulphones Other types of ring contraction are shown by the dihydrothiadiazepine which is obtained from diphenacyl sulphide and hydrazine this, like its S-dioxide, affords 3,6-diphenylpyridazine, whereaas the S-monoxide yields 3,5-diphenylpyrazole

In the fifth paper, Dr A Katritsky of the University of Cambridge described the chemistry of heteroaromatic N-oxides in terms of the capacity of the N—O bond in these compounds to act in appropriate circumstances either as a donor or an acceptor of electrons The various manifestations of this potentially two-fold character were discussed in some detail and provided interesting illustrations of the power of modern physical methods in the interpretation of structure and reactivity in organic molecules The use of proton resonance spectra in distinguishing between tautomeric structures was illustrated by reference to the benzofuroxan–*o*-dinitrosobenzene equilibrium

The evening was marked by a reception and buffet dinner given by Smith, Kline and French Laboratories, Ltd , at their Welwyn research centre, where interest in the displays of specialized equipment added to the enjoyment of the friendly hospitality shown to the participants

The second day of the symposium was opened by a paper by Prof D H Hey and his co-workers of King's College (University of London). Prof Hey described synthetic attempts to extend the Pschorr phenanthrene synthesis to the elaboration of various heterocyclic systems These experiments had revealed anomalous and new reaction-paths, including routes to a number of interesting spirodienones An interesting new intramolecular nucleophilic displacement of a nitro-group as nitrite ion was mentioned, as was a novel intramolecular cyclization involving a benzyne intermediate

Dr A H Jackson of the University of Liverpool gave a valuable account of the application of proton magnetic resonance to porphyrins, for which these spectra are of special interest because they cover such a wide range This is attributed to the large ring-current in the macrocyclic conjugated system Although effects of substituents can in some cases be interpreted on an additive basis, there are some indications that the spectra can be modified if steric effects result in local distortions in the molecule

Dr K Schofield of the University of Exeter gave an account of the stereochemistry of the simple quinolizidines. The infra-red and proton resonance spectra of the isomeric 1-,2-,3- and 4-methyl-quinolizidines were interpreted with reference to the probable conformations of the molecules It was concluded that these studies suggest (contrary to conclusions from other techniques) that the lone-pair of electrons on nitrogen is not more space-filling either than a C—H bond or than a $\equiv\overset{+}{N}$—H bond in aprotic solvents The discussion centred around the position of conformational equilibrium and its relation to protonation

The final paper, by Dr S F Mason of the University of Exeter, described the electronic spectra of related series of heterocyclic compounds in terms of a general model consisting of a conjugated system of carbon atoms from which the heterocyclic compounds are schematically derived by replacement of carbon by hetero-atoms The various types of electronic transitions responsible for visible and ultra-violet spectra were classified, and the formulation of the species responsible for the spectroscopic properties of methiodides of pyridine, quinoline and related compounds was discussed Prof D H Hey, chairman of the final session, closed the meeting with a vote of thanks to the organizers of the symposium

The widespread discussion of heterocyclic molecules in courses for Higher National Certificates in chemistry no doubt plays a part in creating an area of interest which makes it appropriate to hold a symposium of high academic standard on this subject in a college of technology It was clear to all those attending the symposium that great credit is due to Dr R F Robbins, head of the Department of Science at Hatfield College of Technology, for his imaginative forethought and efficient organization of such a successful gathering All the participants will want also to thank the officers and administration of Hatfield College of Technology for making such satisfactory arrangements Some of those present will have returned from this symposium wondering whether they might not expect the registration fees they pay for other conferences to be put as obviously as on this occasion towards the benefit of those who take part in the proceedings Others concerned elsewhere in the finance of scientific education will have been impressed by what can be achieved when good scientists are given the means wherewith to fulfil their vision There are probably some participants, and others who were unable to attend, who may regret that there is no permanent record of the scientific contributions presented at the symposium

COMPARATIVE NEUROCHEMISTRY

FIFTY-FOUR scientists from many different countries met at St Wolfgang, Austria, during June 11–15 for the fifth International Neurochemical Symposium. The topic chosen for this meeting was "Comparative Neurochemistry" and the programme was designed to integrate the available data on differences in structure, chemical composition, metabolism, enzymatic activity and drug and hormone action in the nervous systems of invertebrate and vertebrate species The meeting was interdisciplinary in approach, providing an opportunity for research workers in different fields to relate biochemical and pharmacological data to the morphology and function of nervous structures The formal presentations were followed by lively and prolonged discussion in an atmosphere of informality which promoted the free exchange of information and ideas

The Symposium opened with a discussion of the structural bases for similarities and differences in neural function in different species The organization of nervous structures in invertebrates was described by Dr G A Horridge (St Andrews) The nerve-net of the jellyfish, an anastomosing syncitium of motor neurones acting as a single cell, appears to provide a simple mechanism for the production of co-ordinated, rhythmic motions of the whole body In the polychætes, segmental and whole-body movements may be differentiated by a network of neurones and interneurones with symmetrical synaptic connexions providing a system for conduction of the nerve impulse in either direction As pointed out by Prof V Hamberger (St Louis), spontaneous swimming movements of the whole body prior to individuation of the limbs is the earliest manifestation of neuromuscular activity during the development of vertebrate embryos, although this may be preceded by precocious reflex activity in the case of the mammals Sir Frances Knowles (Birmingham) summarized the present state of knowledge with respect to neurohumoral mechanisms of lower forms In the phylogenetic sequence from molluscs to arthropods, a reduction of neurosecretory elements with a concomitant increase in the complexity of neural structures and connexions appears to occur

Qualitative and quantitative comparisons of the chemical composition of vertebrate and invertebrate nervous systems were presented by several of the participants The bulk and complexity of the data do not permit ready summarization, but, in general, the basic similarities in composition of nervous tissues were more striking than the intraspecies differences, probably reflecting the fundamental unity of cellular organelles, and of membrane and myelin structures in nerve cells throughout the animal kingdom For a given region of the nervous system the chemical composition, especially with respect to lipids of the myelin sheath, nucleic acid content, and patterns of free amino-acids, is characteristic of the stage of differentiation, and is relatively insensitive to changes in the external environment Some interesting features unique to certain forms are the absence of detectable quantities of glycolipids in certain invertebrate species, and the occurrence of distinctive compounds such as threonine–ethanolamine phosphodiester in the brain of some fishes Of interest is the presence of amino-ethylphosphonic acid in the nervous system of some echinoderms

Several papers were presented concerning comparative aspects of the transport of metabolites across nerve cell membranes In a comprehensive review of blood–brain barrier systems, Dr R V Coxon (Oxford) concluded that in the cœlenterates and lower phyla no effective barrier exists between nervous tissue and the extracellular fluid The first indication of isolation of the nervous system from its surroundings occurs at the phylogenetic level of *Branchiostoma*, where a barrier to penetration of foreign substances appears at a relatively late stage of development in higher forms, and appears to be associated with increased vascularization and proliferation of glial elements The maintenance of ionic gradients in nervous tissues of various species in passing from marine to freshwater and terrestrial environments was discussed by Dr H Hillman (London) Although the degree of regulation of extracellular cations may vary widely, in all species studied, the nerve cell behaves fundamentally as a potassium electrode, and the intracellular/extracellular K^+ ratio is regulated in conformity to the Nernst equation

The metabolism of the brain in relation to hibernation received special attention. Prof A V Palladin (Kiev) described a marked reduction in the *in vivo* incorporation of labelled amino-acids into brain proteins during hibernation The biochemical basis of the dramatic increase in body temperature and metabolic rate during arousal from hibernation was discussed by Dr L Mokrasch (Waverley) Changes in the activities of oxidative and glycolytic enzymes do not appear to play a significant part, but it appears possible that activation of phosphorylase, and enzymes (adenosine triphosphatase and acyl phosphatase) capable of cleaving high-energy compounds may be implicated in the mechanism of heat production during arousal

The distribution of neurohypophyseal peptides in different classes was traced by Prof H Heller (Bristol). In the cyclostomes, fish, amphibia and birds, the principal antidiuretic peptide is 8-arginine-oxytocin (vasotocin), in most mammals, including the ruminants, arginine-vasopressin is typical, while in the pig and hippopotamus lysine-vasopressin is characteristic A basic phylogenetic division in distribution of the octapeptides may be traced, but important exceptions to the general pattern exist

Dr D B Carlisle (London) posed a provocative question for the participants in the title of his paper "What makes the Shrimp's Heart Beat Faster ?" One answer proved to be "another shrimp !" but in all, six substances (including two polypeptides, and four indole derivatives) isolated from extracts of the shrimp pericardial organ will produce the same effect The most potent compound has been identified as 5 6-dihydroxytryptamine This compound probably serves to produce instantaneous effects on the heart beat, while the polypeptides appear to account for long-term responses during prolonged stress Other papers were concerned with the distribution and functions of acetylcholine, indoles, catecholamines and other possible neurotransmitter substances in different species

In the final session, devoted to comparative neuropharmacology, the basis of species differences in the sensitivity to drugs was considered The selective toxicity of piperazine, an anthelmintic agent, was shown by Dr E Bueding (Baltimore) to be related to its ability to produce a selective neuromuscular blocking action in *Ascaris* without affecting the neuromuscular junction of the mammalian host As pointed out by Dr D Richter (Carshalton) in the final discussion, the practical value of comparative neurochemistry is evident in the exploitation of such intraspecies differences for the development of new anthelmintics and pesticides

Many excellent papers and interesting commentaries have been necessarily omitted from this brief report I would be remiss, however, if I failed to comment on the fine tissue culture experiments on *in vitro* myelin formation by Prof Margaret Murray (New York), the elegant electronmicrographs of nerve membranes by Dr J D Robertson (Waverley), the stimulating speculations concerning the macro-molecular basis of coding in the memory mechanism by Prof F O Schmitt (Boston), and the techniques used by Dr H Blaschko (Oxford) in estimating the amine oxidase activity of the Malpighian tubules in the cockroach The proceedings of the Symposium are being published in the form of a book, *Comparative Neurochemistry*, edited by Dr D Richter

During our stay, the participants were entertained at receptions and banquets by the Mayor of St Wolfgang, the Mayor of Salzburg and the Government of Upper Austria The hospitality of our Austrian hosts and the beauty and gaiety of the Salzkammergut made this Symposium an exceedingly enjoyable as well as scientifically profitable occasion W C McMurray

THE COLONIAL DEVELOPMENT CORPORATION

THE annual report and statement of accounts of the Colonial Development Corporation for the year ended December 31, 1961*, follows the pattern of the previous report However, the form of the accounts has been altered to give effect to the changes in financial arrangements which the Government announced in April 1961, deferred Government interest currently accruing in 1961 is charged for the first time in the accounts to the extent of some £800,000 The 102 approved projects at the end of the year, totalling £115,770,000, included thirteen new projects totalling some £10 million, of which the largest were the Swaziland Railway Board (£4 25 million), the Trinidad Mortgage Agency Co , Ltd (£1 97 million), the Land Development and Settlement Board, Kenya (£1 5 million) and Northern Rhodesia Africa Housing (£1 million) Four projects were abandoned and one existing project was split into two projects Of the total commitments, £16 454 million was in the Caribbean region, £20 315 million in the Far East, £22 484 million in East Africa, £22 743 million in Central Africa, £20 347 million in the High Commission territories, and £13 427 million in West Africa Functionally, 54 8 per cent of the committed capital in 1961 was for basic development, 34 4 per cent for primary production and processing, and 10 8 per cent for commerce and industry

While the British Exchequer remains the chief source of the Corporation's finance, a steadily increasing part of its investment is financed either by self-generated funds or by loans from sources other than the Exchequer It is emphasized, however, that the Corporation's operations are more immediately likely to be restricted by territories becoming independent with consequent exclusion of the Corporation, despite their continued need for its help, than by shortage of funds, and the total of new projects under serious consideration fell from 38 to 26 during the year The present terms of reference in independent territories are, however, now under review

The report indicates the type of scheme which will receive serious consideration by the Corporation once compliance is established with the Corporation's normal powers Priority is increasingly given to schemes which help the inhabitants of the country to establish themselves as members of an economically self-supporting and ordered community, for example, agricultural small-holder projects, householder mortgage finance companies and local industrial development agencies Through the small-holder schemes also, production of tea in Kenya, palm oil in Malaya, tobacco at Kasungu, Nyasaland, and sugar in Swaziland should yield an increasing volume of cash exports The success of these schemes depends in the long run on other aspects of the territorial economy reaching a certain level of development and affording such projects as power, water supplies, transport and nucleus agricultural estates, the means to investigate and establish the cultivation and management techniques appropriate to small-holder crops, and that high priority be given to production industries which generate the cash exports to service capital investment overseas The Corporation is already committed to nearly £6 million in some fourteen projects for local industrial development agencies.

---

*Colonial Development Corporation Annual Report and Statement of Accounts for year ended 31st December, 1961 Pp vi+90 (London H M Stationery Office, 1961) 5s 6d net

Stress is also laid on the way the Corporation is placed to keep in touch with local circumstances and views The Corporation believes that the presence on the spot of Corporation staff, ready to share the risks of local ventures by equity investment, engenders a sense of partnership not present when development finance is provided only as block loans from abroad. The maintenance of the Corporation's offices and staffs in times of rapid political change certainly provides an essential element of economic continuity, the extent of the management organization implied in the fact that the Corporation itself has at least some responsibility fot the management of more than half the 102 continuing projects is seldom realized Although there is less reference in this report to this training function, the importance of making every effort to train local men for executive posts of responsibility is fully recognized Some success in this direction is reported in the Far East, in the Caribbean and West Africa, while in other parts of Africa the Corporation is concentrating, as a first step, on providing scholarships at agricultural and technical colleges and on project training schemes

MINERAL TECHNOLOGY AT THE IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY

IN 1952 the University of London established at the Royal School of Mines a course in mineral technology leading to a B Sc degree, the first undergraduate course of its kind in the Commonwealth and one of the first in the world In 1961 a new chair was founded (see *Nature*, 190, 1153, 1961) and the inaugural lecture of Prof M G Fleming has now been published by the Imperial College of Science and Technology*

Mineral technology, embracing as it does both the engineering and the scientific aspects of the separation of the valuable mineral constituents from their ores, has its origin in prehistoric times with man's selection and dressing of stones for his tools and weapons, and its long history is closely linked with that of civilization itself Silver from the mines at Laurium built the Greek fleet that defeated Xerxes, and copper from Falun financed Sweden's part in the Thirty Years' War During the twentieth century, more irreplaceable minerals have been consumed than in the whole previous history of the Earth From 1911 to 1959 the world production of iron ore increased from about 130 million tons to 406 million, nickel ores from 24 to 290 thousand tons and sulphur and pyrites from some three million tons to eight times that figure This expanding demand has necessitated the treatment of increasingly low-grade and complex deposits which in the past would have been considered valueless, and mineral dressing which even fifty years ago was still essentially an art has now become a branch of industrial science in its own right How important it is for Britain, not only to keep abreast of the latest developments in this field but also to play the fullest part in new research of all kinds, is evidenced by the fact that Britain no longer has control of enormous quantities of raw material which is necessary for her existence as a leading industrial nation As a result of the granting of independence to many territories much more than half the mineral production of former members of the Empire has already passed out of Britain's hands

It is in order to play its part in this that Prof. Fleming's Department has come into existence Quite apart from its undergraduate work, the investigations already under way range from the determination of heats of adsorption, a study of the mechanism of adhesion of colloidal particles and the kinetics of solvent extraction, to dense-medium separation in hydrocyclones and the beneficiation of concentrates by pelletizing, roasting and leaching This most interesting inaugural lecture concludes with an account of work on flotation in which the necessary reagents are introduced as a fine spray, the separation of ore from gangue being further improved by the application of an appropriate electrostatic charge whereby the droplets of reagent are attracted to the valuable minerals and actually repelled from the particles of gangue

EVALUATION OF THE CARCINOGENIC HAZARDS OF FOOD ADDITIVES

THE Joint Food and Agriculture Organization/World Health Organization Expert Committee on Food Additives met in Geneva during December 12–19, 1960, and, in its fifth report* has recommended the following general basic principles

(1) Food additives should be used for the benefit of the consumer, they should not be permitted for any deceptive or misleading purpose

(2) The use of certain food additives is justified since the present position with respect to world food supplies makes it imperative that good techni-

---

* *W H O Tech Rep Ser*, No. 220 (H M S O, 1961)

cological procedures should be developed and used to a maxima extent

(3) Food materials and all chemicals and processes at present in use for the preparation and distribution of food should be subjected to adequate examination to ensure minimum risk in use, if this has not already been done, or unless previous knowledge indicates that this is unnecessary

(4) All chemicals or processes proposed in the future should be subjected to adequate examination to minimize risk before being accepted for use

(5) The presence of carcinogenic substances in food might be a significant factor in the occurrence of what is considered to be spontaneous cancer in man and animals

(6) Since dose–response relationships have been demonstrated in the case of carcinogenic agents, the reduction of carcinogenic substances in food to the lowest practicable level may be one of the effective measures towards cancer prevention

(7) Many factors may influence dose–response in carcinogenesis Their complexities are such that it is agreed that no assuredly safe level for carcinogens in human food can be determined from experimental findings at the present time

(8) The elimination, or at least the reduction to a minimum, of all proved carcinogenic substances in the diet of man and of animals used as human food is a worth-while objective

In recent years a number of food additives or food contaminants have been suspected of being carcinogenic As a practical approach to the problems arising in this field, the Committee has reviewed the evidence available and the action taken with regard to a number of these substances Many points of interest were revealed, of which the most important are

(*a*) The apparent lack of information on the toxicity or potential carcinogenity of many food additives

(*b*) The inadequacy of the design, execution and interpretation of some experiments or of reported information in some of the publications in this field and the frequent lack of corroborative evidence

(*c*) The need for detailed pathological evaluation of any lesion observed in experimental studies

(*d*) The difficulties arising in interpretation of local sarcoma formation at the site of the injection

(*e*) The difficulty of completely excluding, at the present time, carcinogenic contaminants from food, from processes used in the preparation of food, and from substances coming into contact with food

(*f*) The possibility that some natural constituents of the diet or even an essential nutrient, such as selenium, may constitute a carcinogenic risk Clearly, these substances cannot be completely excluded from the diet

(*g*) The difficulty of carrying out and interpreting epidemiological studies

(*h*) The wide variety of food colours, many of which do not appear to have been adequately tested, including the 'permitted' lists of different countries

(*i*) The necessity for separate assessment of the carcinogenic risk for each individual substance

EARLY FOSSIL RODENTS AND THEIR EVOLUTION

THE literature of science overflows with immature works, but at rare intervals a *magnum opus*, the seasoned fruit of many years patient study, is offered for our digestion Such is *The Early Tertiary Rodents of the Family Paramyidae*, by Albert E Wood, published in the *Trans Amer Phil Soc* (New Series, 52, part 1 Pp. 261 Philadelphia American Philosophical Society, 1962 6 dollars) Behind the innocuous title nestles a major contribution to the study of fossil rodents, a veritable landmark in mammalian palæontology, and a wealth of detailed anatomical, taxonomic and stratigraphic observations for the student of evolution

The paramyids comprise the earliest known rodents of the Upper Palæocene and Eocene When last reviewed by W D Matthew in 1910 [1] he was able to deal exhaustively with the group in thirty pages The size of the present work is a measure of the vast quantity of additional material available for study half a century later Wood begins with a review of the history of the classification of the paramyids, discussing the views of earlier writers on the importance of the paramyids in the evolution of rodents

All but 30 pages of this great work are devoted to a systematic treatise of the family paramyidae Wood states he has examined approximately a thousand specimens, referred to 22 genera and 78 species, ranging from the Upper Palæocene to Upper Oligocene, mainly from North America but including European forms In several instances nearly complete skeletons were available Where material in a sample was adequate he has made variation studies, incisor teeth have been carefully examined and found to be of considerable systematic value Each species is monographed, its probable affinities discussed and where possible the functional interpretation of its characteristics are suggested These details enabled Wood, for example, to reconstruct *Paramys delicatus* as a rat-like animal, rather than the squirrel-like reconstruction of Matthew In two species Wood has been able to recognize a series of sub-species—material for so detailed a study of gens or *rassenkreis* rarely obtains in mammalian palæontology The illustrations are admirable, clearly drawn and well printed it is unfortunate that the phylogenetic tree could not have been three-dimensional

Following the systematic treatise, Wood discusses the interrelationships of paramyids, evolutionary trends within the family, relationships to later rodents, rodents subordinal classification, evolutionary rates in paramyids and the origin of rodents Several of the opinions and interpretations set out here have already appeared in print in earlier writings of the author, nevertheless the summary accompanying the monograph is useful in restating Wood's case alongside his evidence

In discussing evolutionary trends Wood distinguishes three series First, those that can be followed in all or nearly all lines within the family, representing results of selective pressures for increased rodent adaptation, these include continuously growing incisors and reduction of pre-molar dentition. Secondly, those which represent divergent trends characteristic of one or more sub-families as a result of its adaptive radiation; these affect shape of incisors, crest pattern on molars and degree of reduction of last molar. Finally, those which show no significant pattern as in the erratic evolution of the third upper pre-molars. Wood has calculated the rates of evolutionary change which at generic level within the paramyids he found to be similar to those of horses, but in some lines much faster.

Regarding classification, relationships and origin of rodents in general and of paramyids in particular, Wood gives a very fair summary of the views of Stehlin and Schaub[2], his chief rivals, though it becomes patently clear to the reader that the two schools are still very distinct. On the evidence made available in this monograph, together with his interpretation of cusp homologies and the significance of parallelisms, Wood's thesis that "the Paramyidae are ancestral to all other known rodents" seems rather more probable than Schaub's view, based on a different interpretation of cusp homologies, which places the ancestry of the rodents farther back in the Palæocene with the paramyids as specialized descendants and the Oligocene squirrels as structurally the most primitive known rodents. Both views and their consequent implications are plausible analyses of the present evidence; only new evidence can produce an approximation nearer the truth. Wood's monograph enables us to ask more questions about rodent evolution; this is the surest way of unravelling the enigma.

A SUGGESTED RECONSTRUCTION OF THE LAND MASSES OF THE EARTH AS A COMPLETE CRUST

WEGENER'S theory of continental drift is by no means universally accepted by geophysicists[1]. However, as Carey[2] has pointed out, the degree of congruence between Africa and South America, compared at the 2,000-m. isobath, is so great that pure chance can scarcely be the explanation for the fit. Moreover, this theory satisfactorily accounts for the fact that the Earth's granite is collected in the continents, the remaining three-quarters of the Earth's surface, forming the ocean bed, almost certainly consisting of basalt.

An alternative hypothesis is that the Earth was formerly much smaller and was covered by a complete crust of granite, subsequent expansion causing the splitting of the crust and the filling of the cracks by upward movement of the underlying molten basalt. If this hypothesis were valid it would be possible to fit together the outlines of the continents on a small globe, thus representing the Earth in its early state. I attempted to do so before becoming aware of the evidence adduced by Egyed[3] and Heezen[4] that this type of expansion may in fact have occurred, and the outcome provides collateral evidence in support of their views.

It was estimated that the representation of the continents, together with the continental shelf extending to the 1,000-fathom isobath, on a globe 4½ in. in diameter, had a total area which corresponded to somewhat less than the surface area of a 3-in. sphere. The outline of each continent was transferred from such a globe to thin sheets of rubber and cut out. The separate pieces of rubber were then placed on a wooden ball 3 in. in diameter and their outlines marked on the wood, to represent the appearance of the Earth soon after the hypothetical splitting of the crust. Despite the crude method used, the land masses fitted together reasonably well, though there was some distortion of certain regions and there was a triangular gap in the North Atlantic ocean (Fig. 1). It is to be noted that post-palæozoic geology need not be identical in masses which would appear to have been adjacent, as the movements envisaged possibly originated at a much earlier phase. It is difficult to

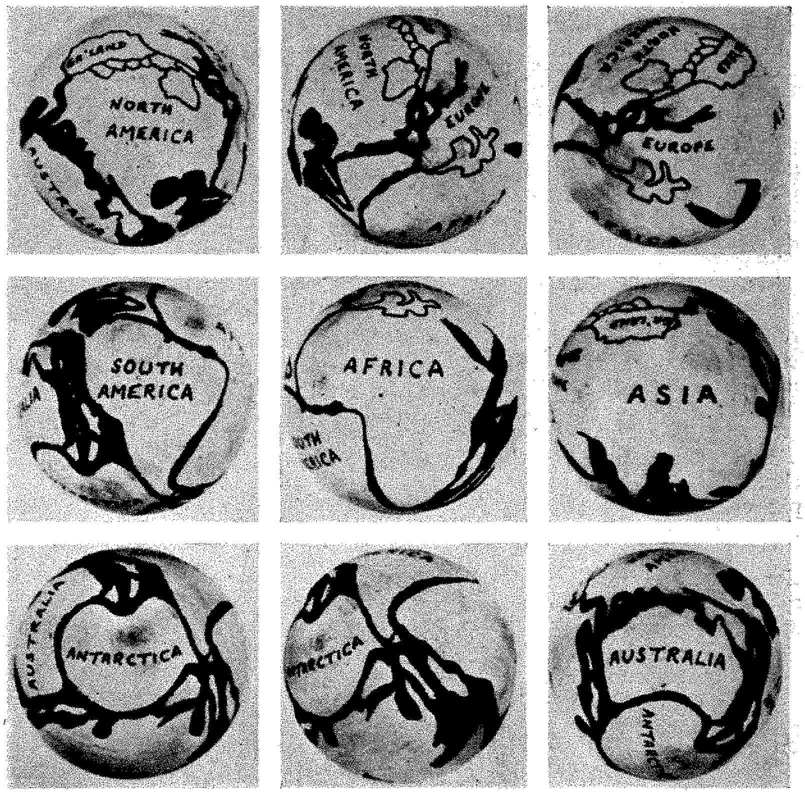

Fig. 1. Nine photographs of the wooden sphere representing the suggested pattern of the continents soon after splitting of the crust

believe that chance alone can explain this fitting together of the continental margins.

I thank Mr. P. S. B. Digby for helpful advice.

C. H. Barnett

Department of Anatomy,
St. Thomas's Hospital Medical School,
London, S.E.1.

[1] Jeffreys, H., *The Earth*, fourth ed. (Cambridge University Press, 1959).

[2] Carey, S. W., *Geol. Mag.*, **92**, 196 (1955).

[3] Egyed, L., *Geol. Rdsch.*, **46**, 101 (1957); **50**, 251 (1960); *Geophysica, Helsinki*, **7**, 13 (1959).

[4] Heezen, B. C., *Sci. Amer.*, **203**, 98 (1960).

It is interesting to see what sort of fit can be produced in accordance with Egyed's ideas. It is better than I should have expected, and will probably give rise to much discussion. Apart from the problem of explaining how the Earth's volume can have increased three-fold, it will probably take some time for structural geologists, palæontologists, meteorologists and magneticians to agree about whether the separation of the land masses occurred soon after the formation of the Earth, in the Palæozoic, or at the end of the Cretaceous.

However, it should be pointed out that areas on a 4½-in. sphere cannot be placed on a 3-in. one without distortion; the rubber must have been stretched, and the quality of the fit must depend on the distribution of the stretching. I cannot, therefore, accept the suggestion that the only alternative to the reconstruction is chance.

I pointed out in the 1929 edition of *The Earth* that Wegener's alleged fit of South America into Africa is a misfit by about 15°. This is obvious on inspection of a globe. The east coast of South America is close to a pair of great circles meeting at 90°; Africa from Liberia to the Cape near a pair meeting at 105°–110°. Nevertheless, drawings have been published until recently showing a good fit. This cannot be produced without considerable distortion, which has disappeared in Barnett's reconstruction owing to the extra curvature downwards in fitting to the smaller sphere.

Dr. Barnett is wrong in claiming that Wegener was the first to explain the differences between continents and oceans. The notion of a light upper layer was due to Airy, based on deflexions of the plumb-line in India, and was extended to the difference between continents and oceans by Suess.

RELEASE OF IODINE-131 FROM IRRADIATED URANIUM OXIDIZING IN AIR AND IN CARBON DIOXIDE

By W. J. MEGAW and J. E. BRIDGES

Health Physics and Medical Division, Atomic Energy Research Establishment, Harwell

We have recently published[1] the results of an investigation into the release of iodine-131 from irradiated uranium. In those experiments the irradiated uranium slug was heated in a vertical channel by a radio-frequency heater and the oxide particles were removed from the heated zone by gravity, or by the circulating gas, as soon as they were formed. We therefore made a distinction between: (*a*) iodine-131 which was released from the uranium as elemental iodine in the gas phase; (*b*) iodine-131 which was released contained in or adsorbed on particles of uranium oxide.

It was apparent from the results that the quantity of iodine-131 in category (*a*) which was released when the oxidation occurred in air, depended to some extent on the rate and quantity of oxidation and had a maximum value of about 30 per cent of the iodine-131 content of the oxidized uranium. In carbon dioxide, however the releases were very much less than this even when, at temperatures above the β–γ phase-transition temperature of 771° C., the oxidation-rates were much greater than in air.

We have therefore made a more detailed examination of the connexion between oxidation and iodine release, at a single temperature 800° C., using the apparatus shown in Fig. 1, which enabled both the oxidation and release of iodine-131 to be followed continuously throughout an experiment of several hours duration. By suitable choice of operating conditions we restricted ourselves to the iodine of category (*a*), that is, elemental iodine in the gas phase.

The uranium disk, about 6 gm. in weight, was supported in a platinum crucible which was suspended in the furnace at *A* from one arm of a balance. In each experiment the uranium was brought up to the working temperature of 800° C. in an atmosphere of argon, and the preheated air or carbon dioxide was then passed in at the top of the reaction vessel. The flow of gas used was 0·2 l./min., which was sufficiently low to ensure the retention of the oxide particles within the crucible. The temperature of the uranium was measured by means of a thermocouple inserted in a small hole drilled in the uranium disk, the difficulty of weighing the specimen continuously

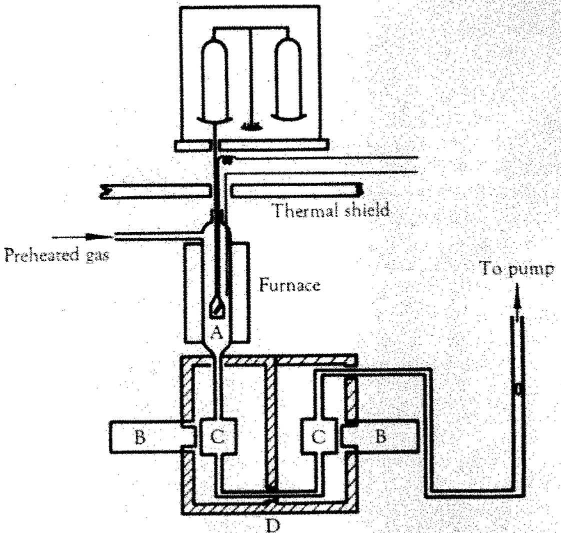

Fig. 1. Experimental arrangement. *A*, irradiated uranium disk; *B*, γ-counters; *C*, iodine samplers; *D*, lead shield

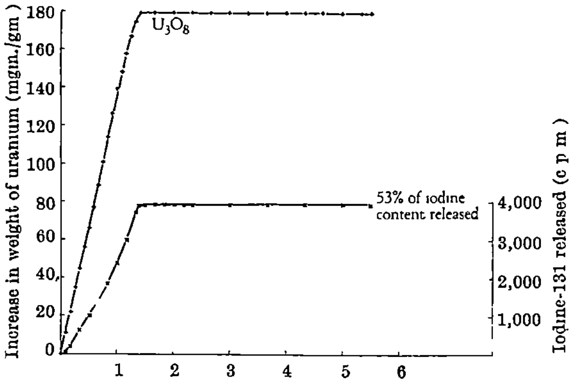

Fig 2. Oxidation of uranium and release of iodine-131 in air at 800° C +, oxidation, ×, release of iodine

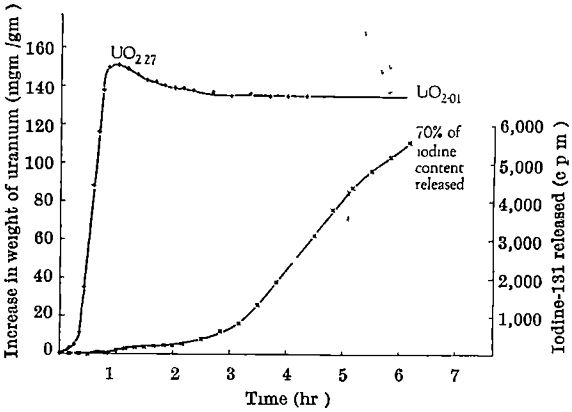

Fig 3 Oxidation of uranium and release of iodine-131 in carbon dioxide at 800° C +, oxidation, ×, release of iodine

while it was carrying a thermocouple being overcome by inserting flexible sections of fine copper wire in the thermocouple leads Parallel check measurements with a conventional thermocouple showed that the addition of the flexible link made no significant difference to the accuracy of temperature measurement.

The gas was passed out of the reaction vessel through a series of iodine samplers which contained in succession two acid-etched copper gauzes, an *AA* grade 'Millipore' filter paper, a charcoal-loaded filter paper and a bed containing 20 gm. of granulated activated charcoal Samplers of this type have been found to be highly efficient for all known forms of airborne iodine and are described more fully by Megaw and May[2] As the experiment proceeded the build-up in the sampler of iodine released from the oxidizing uranium was followed by means of a γ-scintillation counter

The experiments were continued for several hours after oxidation was complete, in order that any subsequent release of iodine or changes in weight of the uranium could be followed After each experiment radiochemical analyses for iodine were performed on uranium wires, which had been irradiated in holes in the uranium disk, and on samples of the oxide so that the percentage of the iodine originally present in the uranium disk which was released during the experiment could be determined The analytical method used was that given earlier by us[1]

Typical results are given in Figs 2 and 3, in which the increase in weight of the uranium disk and activity of iodine-131 in the samplers are plotted against time for oxidation in air and carbon dioxide respectively In Fig 2 it is seen that in air the uranium oxidizes to a weight which corresponds to a composition of U_3O_8, and that the iodine is released during the period of oxidation The release of iodine ceases when oxidation is complete and about 50 per cent of the iodine content of the uranium has been released. Fig 3 shows that in carbon dioxide the uranium oxidizes initially to a weight which corresponds to a composition of $UO_{2\cdot3}$ and during the period of oxidation virtually no iodine is released As heating continues, the uranium oxide loses oxygen and releases iodine, and after several hours has a weight corresponding to a composition of $UO_{2\cdot0}$ By then about 70 per cent of its initial content of iodine-131 has been released Substantial releases of iodine only begin when the oxide has practically reverted to UO_2.

The reason for this behaviour is not understood According to Katz and Rabinowitz[3], the oxides of uranium in the range $UO_{2\cdot0}$ to U_3O_8 are solid solutions of oxygen in uranium dioxide It is possible that the iodine atoms, which are formed at random in the uranium, are held in the uranium dioxide lattice in the same manner as the dissolved oxygen atoms and released with them when the oxide reverts to uranium dioxide

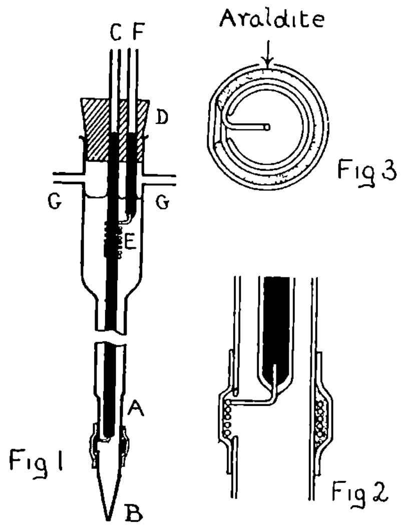
A DIFFUSION-CONTROLLED CATHODE FOR THE MEASUREMENT OF OXYGEN TENSIONS

By Dr R W PITTMAN

Department of Chemistry, Birkbeck College, London

A NUMBER of diffusion-controlled electrodes for the estimation of oxygen tensions by cathodic reduction have been described[1,2] However, in general, they lack robustness, and this is a grave disadvantage in many practical usages such as in biological fermentations where sterilization is essential The electrode described here was designed to overcome this fault and was rendered possible by the particular properties of silicone rubber

The body of the electrode (Fig 1) was made of 'Pyrex The dimensions, which are really defined by the apparatus to which the electrode is ancillary, are not critical, except for the lower end *A B* which carries the cathode and diffusion membrane In the prototype electrode this end was made from a length of 'Pyrex' tubing of 6 5 mm external diameter, fused at the top end *A* to the main body of the cell and drawn off gradually to a rounded point at the lower



Figs. 1–3

end *B*. A hole, 2 mm. in diameter, with smooth edges, was blown in the wall of this tube, approximately equidistant between *A* and *B* to allow the wire forming the cathode to pass from the inside to the outside of the cell. The cathode consisted of a pure platinum wire, 0·014 in. in diameter, of sufficient length to give five complete turns on *A B*, after being sealed into the soft glass tube *C* which acted as a mercury contact tube and which was supported at the other end by the rubber bung *D*. Before the final positioning of the cathode the anode *E* was fitted. This comprised approximately 9 in. of silver wire, 0·028 in. in diameter, joined by fusion to a short length of platinum wire for sealing into the contact tube *F*, and after this tube was inserted into the bung *D*, the silver wire was wound in a close spiral around the contact tube of the cathode. The bung carrying these electrodes was then inserted into the cell so that the end of the contact tube of the cathode came as close as possible to the hole in *A B* through which the platinum wire passed. Five turns of this wire were then wound tightly around the outside of the tube so as to cover the hole (Figs. 2 and 3) and the free end sealed down with 'Araldite'. When this had set, the whole of the wire, except that immediately adjacent to the hole, was thinly coated with 'Araldite', so as to leave an area of 6–8 mm.^{2} of bare wire covering the hole. When this insulating layer was completely hardened, the diffusion membrane, which consisted of a length of about 2 cm. of a proprietary silicone rubber ('Escorubber') tubing of 1·5 mm. bore and 0·5 mm. wall, was fitted. This was accomplished by lubricating the tube *A B* and the cathode assembly with a few drops of a 20 per cent aqueous solution of 'Teepol' and then carefully sliding the silicone rubber tubing over the tapering end and along the tube until the cathode was completely shrouded (Fig. 2).

During this operation the wall of the silicone tube became considerably stretched and much thinner. Electrolyte, 0·5 *M* aqueous ammonium chloride, was then added to the cell until the level was such that the silver anode was completely submerged. Ammonium chloride was used instead of the more conventional carrier electrolyte, potassium chloride, because of the adverse effect on the silicone rubber sheath of the high alkalinity developed around the cathode, in solutions of this salt, on prolonged working of the cell. This frequently resulted in rupture of the sheath.

Before measurements could be made it was necessary to remove dissolved oxygen from the cell, and this was done by placing the cathode bearing end in an atmosphere of nitrogen, passing a slow current of nitrogen through the anode compartment via the tubes *G G* and applying a steady potential difference of 0·5 V. across the cell in the appropriate sense. Left overnight in these circumstances the current, measured by a 0–50 microammeter in series with the cell, became zero. The response curve of the electrode, that is, the current passed by the cell at a constant applied potential difference, plotted against oxygen pressure, was linear between 0·0 and 0·2 atmospheres of oxygen. At oxygen pressures above 0·2 atmospheres the curve drooped from linearity. Thus the electrode could be calibrated for use in aerated systems simply by means of air. The electrode will operate either in a liquid or a gaseous environment and the responses are similar; nevertheless, it seems advisable to calibrate the instrument in the medium in which measurements are to be made. In liquids, vigorous stirring is essential to dissipate secondary diffusion gradients, and it is necessary, because of the considerable temperature coefficient of diffusion of oxygen in the controlling membrane, that calibration be done at the same temperature at which measurements are made.

The selection of 0·5 V. for the polarizing potential difference was not arbitrary. It was observed with a gold electrode in this cell that, at a polarization between 0·55 and 6·0 V., a change of mechanism of oxygen reduction occurred which loosely corresponded with a switch from a two to a four electron process. With platinum such a change has not yet been observed; nevertheless, over the same polarization range anomalous behaviour was noted, hence it was thought wise to limit the polarizing potential difference to 0·5 V.

Measurements with the electrode are easy, for it may be poked through a bung and into an apparatus just like a thermometer. With a polarization of 0·5 V. and a diffusion membrane made from silicone rubber tubing of 0·5 mm. wall and 1·5 mm. bore the response time was relatively small; the current became constant within 10 min. of a change of oxygen pressure from 0·0 to 0·2 atmospheres in a gaseous ambience. With a thicker membrane for which tubing of 0·8 mm. wall and 2·5 mm. bore was used a steady current reading was obtained within 30 min. for the same change of conditions.

In systems uncontaminated with catalyst poisons this electrode behaved reproducibly, but in 'dirty'

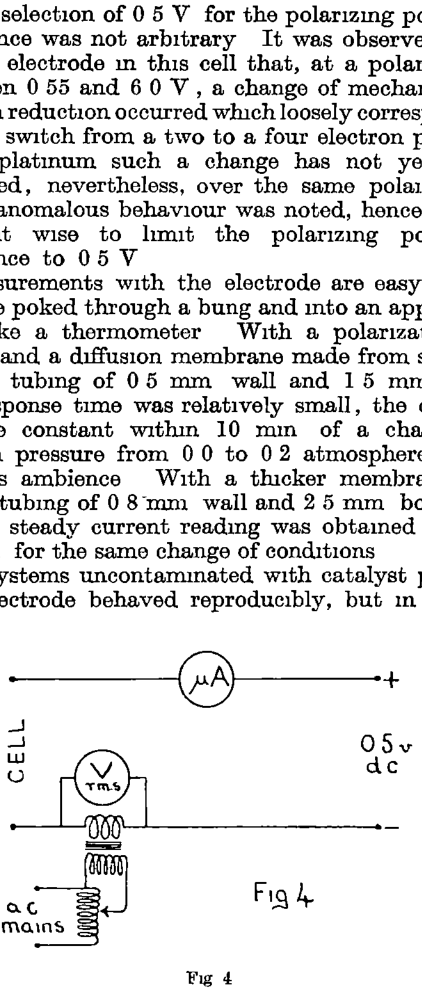


Fig. 4

systems, for example, spent media from long-term continuous bacterial cultures, poisoning was rapid and the electrode ceased to respond to changes of oxygen tension. This effect was neutralized in a simple way, namely, by imposing an alternating voltage, of the order of 1.0 V (root mean square), on the direct polarizing potential by connecting the secondary to a suitable transformer (a 6-V microscope lamp transformer, with a low impedance secondary, serves admirably) in series with the cell and the source of the direct polarizing potential difference, the primary of this transformer being connected to the a.c. mains through a Variac variable auto-transformer (Fig. 4). The magnitude of this a.c. signal was not critical. It was found to depend on the rate at which poisons reached the cathode, but in all experiments, so far, any value between 0.5 and 2.0 V (root mean square) seemed to serve. If the a.c. signal was applied from the start of a run with an initially unpoisoned electrode, poisoning did not supervene. Also, if it was imposed even on a heavily poisoned electrode, 'clean up' took place in a time dependent on the extent of the poisoning and the magnitude of the signal.

The imposition of this signal necessarily modified the technique of measurement. This arose because, in clean systems, rectification occurred, owing to the depolarizing action of oxygen, during the negative going swing, while in dirty systems rectification occurred in the positive going swing, at least some of the 'clean up' being due to oxidation. This means that the reading of the d.c. microammeter with the a.c. signal imposed was in part dependent on the concentration of poison in the system. The procedure which was adopted to deal with this was to impose both alternating and direct voltages from the beginning of an experiment and to turn off the alternating component when a reading was required, allowing a sufficient length of time, which was about 2 min., for a steady microammeter reading to be attained.

PLASMA PROTHROMBINASE

By Dr. M. J. CROSS

Department of Pharmacology, Royal College of Surgeons of England

WHEN a mixture of normal plasma, normal serum, platelets and calcium chloride is incubated at 37° C it develops the ability to accelerate the clotting of recalcified normal plasma and to convert partially purified prothrombin into thrombin[1]. If such a mixture is centrifuged at high speed and the sediment resuspended in a suitable buffer, the resuspended sediment is found to possess most of the activity of the original mixture[2–4]. It is probable that the active component of such sediments is also formed during normal blood coagulation and is responsible for the conversion of prothrombin to thrombin under physiological conditions.

Recently, I have described a method of preparing and partially purifying this active component from pig plasma, using a modification of the thromboplastin generation system of Biggs and Douglas[1]. The product appears to act directly on prothrombin, converting it to thrombin[5], and the kinetics of the conversion, which will be reported elsewhere, are as would be expected if the material were an enzyme. I therefore feel justified in describing the material as a prothrombinase, and I shall refer to it as plasma prothrombinase to distinguish it from prothrombinase derived from tissue extracts[6].

In the experiments to be described here the activity of prothrombinase was estimated by adding 0.1 ml of a suspension of prothrombinase in iminazole buffer containing 6×10^{-3} M calcium chloride to recalcified citrated plasma and measuring the clotting time. A suspension of prothrombinase which clotted the plasma in 10 sec was arbitrarily taken to contain 100 units of prothrombinase per ml.[5]

The most active suspensions of prothrombinase which I have prepared contained 300–550 units per ml. They contained 23–26 μg protein, as measured by the method of Lowry *et al.*[7], and 0.22–0.45 μg of lipid phosphorus per 100 units of prothrombinase. Lipid phosphorus was extracted by the method of Folch, Lees and Sloane Stanley[8], and estimated by a modification of the method of Berenblum and Chain[9] (Sloane Stanley, G. H., personal communication). In Table 1 these results are compared with the activities of other potent preparations of natural coagulants. In terms of lipid *P*, my plasma prothrombinase had 50–100 times more thromboplastic activity than the most active suspensions of plasma thromboplastin isolated from a similar thromboplastin generation system by Bentley and Krivit[10]. In terms of protein my plasma prothrombinase had about 2 per cent of the thromboplastic activity of the purest thrombin that has been made[11].

Table 1. COMPARISON OF THE ACTIVITY OF PROTHROMBINASE WITH A SIMILAR THROMBOPLASTIN (REF. 10) AND WITH THROMBIN (REF. 11)

Preparation	Clotting time (sec) of recalcified plasma on adding 1.0 ml sample	Protein μg/ml	Lipid P μg/ml
Partially purified prothrombinase	10	23–26	0.22–0.45
Thromboplastic sediment from thromboplastin generation test (ref. 10)	9.6–10.6	—	8–35
Thrombin (ref. 11)	*c.* 10*	0.5	—

* Calculated from the activity of this preparation of thrombin, which was 4,100 units/mg.

Suspensions of plasma prothrombinase in iminazole buffer were fairly stable at 4° C, losing about 50 per cent of their activity in one week, at *p*H 6.6–7.0, but the activity was lost much more rapidly at *p*H values below 6.1 or above 7.6. Heating to 70° C for 30 min abolished activity almost completely[5]. Even when, under these conditions, the suspensions had lost their own prothrombinase activity they could still replace platelets in the modified thromboplastin test. Since platelets can be replaced in this test by certain phospholipids[3,4], these procedures presumably denature a protein component of prothrombinase, leaving a phospholipid component intact. This confirms earlier observations with cruder preparations[2].

Table 2 Recovery of Prothrombinase Activity after Centrifugation in the Presence and Absence of Calcium

The recoveries were recorded as a percentage of the prothrombinase activity initially present

	Calcium present			Calcium absent		
Experiment	Sediment	Supernatant	Mixed sediment and supernatant	Sediment	Supernatant	Mixed sediment and supernatant
1	57	31	104	7	21	75
2	47	26	98	16	22	107
3	62	13	75	7	19	75

Plasma prothrombinase was fully active only when suspended in a buffer containing calcium[4,5] The requirement for calcium has been investigated by measuring the recovery of prothrombinase in fractions obtained by centrifuging it in the presence and absence of calcium The results of three typical experiments are shown in Table 2. When a suspension of plasma prothrombinase in iminazole buffer containing 6×10^{-3} M calcium chloride was centrifuged for 30 min at 200,000*g* and the sediment resuspended in the same buffer mixture, 47–62 per cent of the original activity was recovered in the sediment A further 13–31 per cent was recovered in the supernatant, giving a total recovery of 73–88 per cent When the sediment and supernatant fractions were mixed together again the activity was often a little greater, that is, 75–104 per cent, than the sum of their separate activities When, on the other hand, a suspension of plasma prothrombinase in iminazole buffer not containing calcium was centrifuged in the same way the original activity became distributed very differently While the supernatant still contained 19–22 per cent of the initial activity, only 7–16 per cent was now recovered in the sediment However, when the supernatant and sediment fractions were mixed together at 0° C, the activity of the mixture increased to 75–107 per cent. Therefore, after centrifuging prothrombinase in the absence of calcium, its activity was only recovered by mixing the sediment and supernatant, and the activity of this reconstituted prothrombinase was equal to that of the prothrombinase centrifuged in the presence of calcium Similar results were obtained when 5×10^{-4} M sodium ethylenediaminetetraacetate was added to the suspension of prothrombinase in buffer without calcium in order to bind any remaining calcium ions before centrifugation.

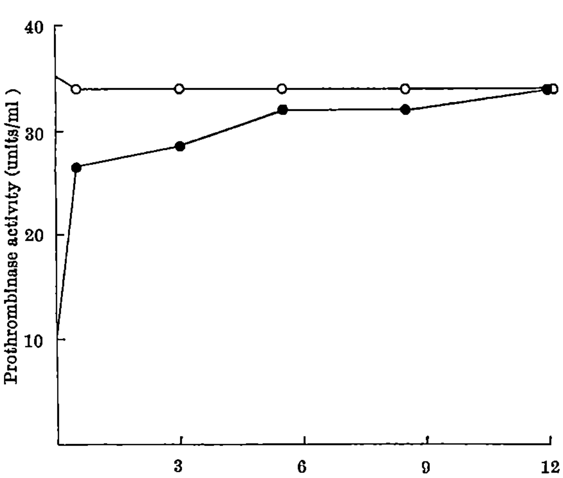

Fig 1 Changes in prothrombinase activity when sediment and supernatant obtained by centrifuging prothrombinase are mixed The two fractions were obtained by centrifugation in the presence (○) and in the absence (●) of calcium In both cases the activities shown at zero time were the sum of the activities of the two fractions tested separately

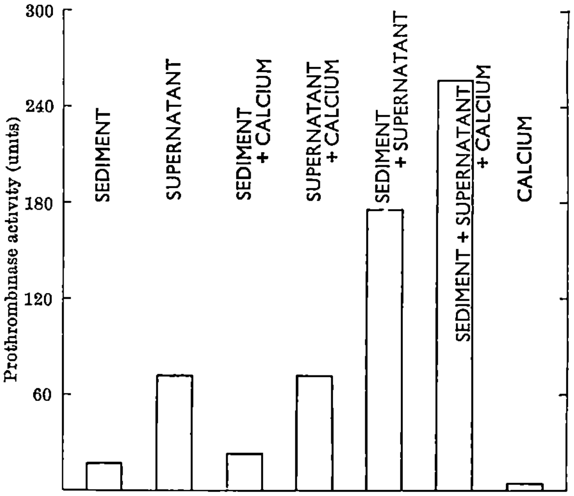

Fig 2 Effect of calcium on the activities of sediment and supernatant obtained by centrifuging prothrombinase in a medium lacking calcium

These results suggest that, in the absence of calcium, plasma prothrombinase splits into two components, one of which is largely deposited when centrifuged at 200,000*g* while the other is not If these two components are mixed in the presence of calcium the full activity of the prothrombinase is restored Fig 1 shows that, after mixing, the full prothrombinase activity took several minutes to develop, suggesting that some definite reaction must take place between the two components in order to reform plasma prothrombinase Fig 2 shows that the maximum activity only developed when the sediment, the supernatant and calcium chloride were all present

When the *sediment*, suspended in buffer containing calcium, was heated at 70° C for 30 min, it lost most of its intrinsic prothrombinase activity However, it was still able to restore some prothrombinase activity to the supernatant fraction when they were mixed in the presence of calcium (Table 3) It seems, therefore, that the component of plasma prothrombinase which is deposited on centrifugation in the absence of calcium is relatively heat-stable It is probable that this component is phospholipid because the sedimented fraction, like plasma prothrombinase itself, could replace platelets in the modified thromboplastin generation test, both before and after being heated at 70° C for 30 min In contrast, the *supernatant* fraction could not replace platelets, so that it presumably contains little phospholipid The supernatant fraction, like the sediment, lost its small intrinsic prothrombinase activity when heated at 70° C for 30 min When heat-treated supernatant was mixed with normal sediment in the presence of calcium, the mixture had little activity (Table 3) Therefore, the component of plasma prothrombinase remaining in the supernatant is heat-labile

Twenty years ago Macfarlane suggested that blood thromboplastin, the activator of prothrombin, might consist of two separate substances, one being a water-soluble enzyme and the other a lipid[12] He cited the analogy of the action of Russell's viper venom which accelerates clotting only in the presence of certain lipids More recently, a thrombokinase which is potentiated by cephalin or by platelets has been isolated from plasma[13] In 1956 Bergsagel and Hougie

Table 3. EFFECT OF HEAT ON THE FRACTIONS OF PROTHROMBINASE OBTAINED BY CENTRIFUGATION IN THE ABSENCE OF CALCIUM

Sample	Prothrombinase activity (units)
Unheated sediment	22
Unheated supernatant	30
Unheated sediment mixed with unheated supernatant	195
Heated sediment	7
Heated supernatant	8
Unheated sediment mixed with heated supernatant	40
Heated sediment mixed with unheated supernatant	145

Each fraction was heated at 70° C for 30 min in iminazole buffer containing calcium chloride.

obtained evidence that a reaction occurs between a calcium–protein complex (product 1) and platelets to yield a coagulant which can be sedimented by centrifugation[2]. This was in general accord with Macfarlane's view but suggested that prothrombinase might be a single complex of protein, lipid and calcium.

The properties of the prothrombinase which we have partially purified support this conclusion. Prothrombinase is apparently made up of two parts, one consisting of protein and the other of phospholipid, which are bound together by calcium. There were about 20 moles of protein nitrogen to 1 mole of lipid phosphorus; this ratio is of the same order as that found in the major serum lipoproteins. The complex is dissociated by reducing the concentration of calcium in the suspension medium and this process is reversible. This may account for the requirement for calcium in the formation of thrombin from prothrombin.

USE OF DIHYDROFOLATE REDUCTASE AS A BIOCHEMICAL INDEX OF CHEMOTHERAPY

By STEWART R. HUMPHREYS, DR. LOUIS B. THOMAS, DR. MICHAEL A. CHIRIGOS and DR. ABRAHAM GOLDIN

Laboratory of Chemical Pharmacology and Pathologic Anatomy Branch, National Cancer Institute, Bethesda, Maryland

AND

ELIZABETH J. CRAWFORD and PROF. MORRIS FRIEDKIN

Department of Pharmacology, Tufts University School of Medicine, Boston, Massachusetts

IT has been demonstrated that, on continuous therapy in serial transfer of murine leukæmia, the leukæmic cells may become markedly resistant to treatment with antifolics[1,2]. Several of the resistant sub-lines of leukæmia *L*1210 established in this manner[3–5] have been shown to have a high level of dihydrofolate reductase activity[6,7]. Both the resistance to therapy with folic acid antagonists and the high level of folic reductase, once present, appear, in large measure, to be heritable[7]. The possibility was considered that resistant leukæmic cells with high levels of dihydrofolate reductase might serve as biochemical markers, to measure the efficacy of chemotherapy. This appeared feasible, since the high levels of dihydrofolate reductase could readily be measured in tissues showing any extensive degree of invasion by leukæmic cells.

There has been considerable interest in the contribution of spread of leukæmic cells in the brain and meninges, and in the inability of the drug to reach the brain site, to the ultimate failure of therapy with effective compounds[8–11]. In the present experiment, the anti-leukæmic action of *N,N,bis*-(β-chloroethyl)-*N′*, *O*-propylene phosphoric acid ester diamide ('Cytoxan', obtained from Mead Johnson and Co., through the courtesy of the Cancer Chemotherapy National Service Center) is studied from the foregoing point of view. For this purpose, the animals were inoculated intracerebrally and the 'Cytoxan' was administered subcutaneously. The following questions were asked: (*a*) Will 'Cytoxan' increase the survival-time of mice bearing an amethopterin-resistant sub-line of leukæmia, inoculated intracerebrally? (*b*) What effect does therapy with 'Cytoxan' have on the transplantability of tissues of the leukæmic mice? (*c*) Does the level of dihydrofolate reductase reflect the therapeutic effect? (*d*) What effect does therapy have on the distribution of leukæmic cells, particularly in the brain and meninges? A detailed account of the pathological anatomy is presented separately[12].

The model experiment was conducted with the *FR*-9 amethopterin-resistant sub-line of leukæmia *L*1210 (ref. 7). The history of the *FR*-9 sub-line may be summarized as follows. The sensitive leukæmia *L*1210 had been treated for ten generations with amethopterin (0.75 mgm./kgm./day) and was then maintained for ten generations without treatment. The tumour was then subjected to treatment again, using progressively increasing doses of amethopterin (from generation 21 to generation 31). It was then carried for 12 generations without treatment, at which time it was used in the present experiment. The dihydrofolate reductase activity of the *FR*-9 leukæmia sub-line ranges from values of 2,000–4,000 (mμmoles dihydrofolate reduced/mgm. protein/hr.) for infiltrated spleen or tumour. This is approximately 50 times greater than that observed for the sensitive line of *L*1210 (ref. 6).

In the model experiment the leukæmic inoculum consisted of 0.05 ml. of a 1:10 dilution in normal

Table 1 Effect of Treatment with 'Cytoxan' on the Growth of Intracranially Inoculated Amethopterin-Resistant Leukæmia (*L*1210 *FR*-9) as determined by Pathological Examination, Retransplantation of Tissues and by Enzymatic Assay*

‡ $m\mu$moles dihydrofolate reduced per mgm. of protein per hour at a temperature of 32°

§ 0 to ± little to no leukæmic infiltration + to + + moderate leukæmic infiltration + + + to + + + + extensive leukæmic infiltration

¶ Accidental deaths not included

‖ The inoculation may have been unsuccessful for this mouse.

saline of whole blood from an *FR*-9 leukæmic mouse The inoculum was injected intracerebrally, by use of a microlitre syringe with a 25-gauge needle[9] The experiment was conducted with *DBA*/2 male mice, approximately 3–4 months of age

The 'Cytoxan' was dissolved in normal saline and administered in 0 01 ml of vehicle per gram of body weight, subcutaneously, in the axillary area The treatment was initiated on the fourth day following leukæmic inoculation and continued daily The animals were observed for survival-time, or were killed for transplantation of tissue, determination of dihydrofolate reductase activity, and for pathological examination, as indicated in Table 1

The first two groups of animals (untreated leukæmic controls, group 1, treated leukæmic animals, group 2), containing ten animals per group, were not killed, but were used for determination of survival-time The untreated leukæmic group (group 3) had 14 mice Each of the remaining groups contained eleven mice Six of the mice from group 3 and three from each of the remaining groups were killed for pathological investigations Three of the mice were killed, and pooled brain and pooled spleen mash prepared in normal saline and inoculated into *DBA*/2 mice at 1 10, 1 100, 1 1,000 and 1 10,000 dilutions Each of the recipient mice was injected subcutaneously with 0 1 ml Five of the mice were killed, and enzyme determinations made of pooled brain and pooled spleen Treated animals were killed one day following discontinuance of therapy This was done in order to permit the elimination of any transformation product of 'Cytoxan'[13] which might interfere with the assay of dihydrofolate reductase 'Cytoxan', at a final concentration of 3 2 × 10^{-3} *M*, was found not to inhibit leukæmic dihydrofolate reductase *in vitro*

For the determination of dihydrofolate reductase, the tissues were quick-frozen in beakers submerged in solid carbon dioxide and acetone The preparation of the acetone powder and the spectrophotometric assay for dihydrofolate reductase has been described previously[6] Protein was determined by the method of Lowry *et al* [14] The dihydrofolate reductase activity is expressed in $m\mu$moles of dihydrofolate reduced per mgm of protein per hour at a temperature of 32°

The results are summarized in Table 1 (ref 12) The untreated control animals with intracerebral leukæmia (group 1) showed a median survival-time of 8 days (range 8–9 days) The animals treated with 75 mgm / kgm of 'Cytoxan' daily from day 4 (group 2) showed a median survival-time of 15 days (range 9–17 days)

On the fourth day following intracerebral inoculation of the leukæmia (the day on which therapy was initiated), pathological observation of untreated controls (group 3) revealed only moderate infiltration of the spleen, liver and marrow (Table 1) At this time transplantation of a 1 10 to 1 1,000 dilution of spleen suspension did result in progressive tumour growth and death However, the degree of infiltration was apparently not very extensive since the transplants grew slowly and the animals showed rather prolonged survival-times (group 3) The untreated animals killed on the fourth day showed fairly extensive diffuse leukæmic cell infiltration of the arachnoid space and the dura Although the leukæmic cells had been inoculated directly into the brain, diffuse growth of leukæmic cells in the brain tissue was not observed The number of leukæmic cells growing in the arachnoid space was apparently less than the number of leukæmic cells growing in the spleen since brain inoculum taken on the fourth day was less potent than spleen inoculum taken from the same animals Three re-transplants from the brain succumbed with the 1 10 dilution, but only one out of three animals died with the 1 100 dilution from brain (group 3)

That the infiltration of spleen and brain was not extensive on the fourth day after leukæmic inoculation is also indicated by the low values for dihydrofolate reductase in spleen (39 8) and brain (30 8) These values would appear to be somewhat above the range for normal spleen[6] and brain, both of which have little to no measurable enzyme

On the seventh day following intracerebral inoculation of the leukæmia, there was extensive infiltration of the spleen, liver and bone marrow (group 4) The arachnoid and dura were also heavily infiltrated and there were a few leukæmic cells in the perivascular spaces of the brain. The increase in the number of cells was reflected in the results obtained on transplantation of tissue of spleen and brain. With transplant of spleen tissue, 3 out of 3 animals died at a 1 : 10,000 dilution of the inoculum. With brain, 3 out of 3 animals died at a 1 : 1,000 dilution of the inoculum. As compared with the fourth day, transplantation of both spleen and brain resulted in a reduction in the time to death. At the 1 : 10 dilution of spleen and brain the median survival-times were 8 days and 11 days respectively.

On the seventh day following leukæmic inoculation, the spleen showed a very high value for dihydrofolate reductase activity (2,980) and the brain also showed an increased value (243). As compared with the fourth day, the activity of the spleen was increased approximately seventy-fold, and the activity of the brain was increased approximately eight-fold.

The treated mice killed on day 7 (group 5) had received three injections (days 4, 5 and 6). At this time autopsy of the animals and histological study revealed a virtual disappearance of the leukæmic cells from the spleen, liver and bone marrow, and from other extracranial tissues. Also, there was almost a complete disappearance of leukæmic cells from the cranial and spinal cord dura. On the other hand, there was no definite evidence of a decrease of leukæmic cell infiltration in the arachnoid space. The transplantability of the spleen was reduced below that of the untreated controls on day 4 or day 7. Following therapy, the transplants of spleen grew with the 1 : 10 dilution of inoculum, but there were 'no takes' in three animals inoculated with the 1 : 100 dilution. In contrast, as compared with the corresponding untreated controls, there was only a slight reduction in the ability of the brain to 'take' on transplant. That there was some decrease in the total number of the leukæmic cells in the arachnoid space is suggested by the observation that the median survival-time for the brain transplants was slightly increased as compared with the corresponding controls.

The depletion of leukæmia cells in the spleen, following three days of therapy, was reflected in the relatively low value of dihydrofolate reductase for the spleen (56.1).

Despite therapy with 'Cytoxan', there was a substantial increase in the value for dihydrofolate reductase of the brain (129). This value was lower, however, than that observed for the untreated leukæmic controls for the seventh day, suggesting again that there was some retardation of leukæmic growth on therapy.

On the eleventh day (after a total of seven injections, the last injection was given on day 10), the pathological findings were similar to those seen on treatment to the seventh day (group 6). The somatic tissues appeared to be devoid of leukæmic cells, but the arachnoid space was densely infiltrated. In addition, the infiltration in the intracerebral perivascular spaces was more extensive than previously observed. The reduction in the number of leukæmic cells in the spleen was maintained so that only two out of three transplants took successfully at a 1 : 10 dilution. The median survival-time was 22.5 days. There was a slight increase in the number of takes on transplant of brain tissue, one out of three animals succumbing at a 1 : 10,000 dilution. The decrease in the number of cells in the spleen was reflected by a further decrease in the dihydrofolate reductase activity (20.5). In contrast, the dihydrofolate reductase of the brain on the eleventh day was 280.

On the fourteenth day (therapy days 4–13) there was still no evidence of leukæmic cells in the spleen, liver, bone marrow or other extracranial tissues (group 7). There was a dense infiltration of leukæmic cells in the arachnoid space and deep infiltration in the fissures between the lobes of the brain. There was progressive increase in the number of cells infiltrating the intracerebral perivascular spaces and along the intracerebral needle track. Only one tumour take occurred on reinoculation of the spleen, at a 1 : 10 dilution. The dihydrofolate reductase of the spleen remained at a very low level (18.5). Brain tissue continued to give 100 per cent takes down to a 1 : 1,000 dilution, and the dihydrofolate reductase remained at a high value (298).

The present investigation illustrates a close correlation of biochemical, biological and pathological observations on the influence of 'Cytoxan' on the growth of a sub-line of leukæmia *L*1210 with high dihydrofolate reductase. The 'Cytoxan' was effective in increasing the survival-time of the animals. The survival-time was approximately doubled over that of untreated controls. There was good correlation of the value for dihydrofolate reductase, the retransplantability of the tissues, and the pathological findings. Regression of the systemic disease was virtually complete after treatment with 'Cytoxan', as shown by study of histological sections and by the low level of dihydrofolate reductase activity in the spleen and the reduced transplantability of spleen suspension. The leukæmic cell infiltrate in the arachnoid space appeared to progress despite successful systemic therapy. This was associated with a progressive increase in dihydrofolate reductase in the brain, and the success of re-transplant with brain tissue inoculum.

Enzymatic markers of this type may be useful in investigations of fate and distribution of drugs, and studies of the blood-brain barrier. They may be employed in investigation of tumour invasiveness, and the efficacy of therapy and the origin of resistance[7,15]. High dihydrofolate reductase in antifolic resistant leukæmia can serve as a biochemical marker which, in conjunction with biological and pathological studies, may provide a means for detailed investigation of chemotherapeutic agents.

REACTION OF CYTOCHROME *a* WITH CHEMICALLY MODIFIED CYTOCHROME *c* AND BASIC PROTEINS

By SHIGEKI TAKEMORI, KEISHIRO WADA, ICHIRO SEKUZU and KAZUO OKUNUKI
Department of Biology, University of Osaka

IN previous communications[1], we have suggested not only that cytochrome *c* acts as an electron donor but also that it has some coenzymatic function in the cytochrome oxidase reaction The questions are what part of the protein moiety of cytochrome *c* plays the essential part in the reaction with cytochrome *a* and how These questions may be partly solved by studying the reaction between cytochrome *a* and cytochrome *c* chemically modified by substitution on the functional groups As cytochrome *c* is a strongly basic protein with an isoelectric point at about *p*H 10 5 (ref 2) and as lysine constitutes about 20 per cent of the total amino-acid residues[3], the blocking of the amino-groups was first undertaken

The activity of a chemically modified cytochrome *c* such as acetyl or succinyl-derivative in the cytochrome oxidase reaction was measured with a highly purified preparation of cytochrome *a* from bovine heart muscle

As shown in Table 1, the cytochrome *c* with more than 32 per cent of the amino groups acetylated or more than 22 per cent succinylated showed no activity in the cytochrome oxidase reaction when the Warburg manometric method was used The reducibility of the cytochrome *a* by the chemically modified cytochrome *c*'s was estimated spectrophotometrically by the appearance of the absorption at 605 mμ of cytochrome *a* after the addition of hydroquinone as an electron donor to the reaction mixture As shown in Fig 1, the reducibility of the cytochrome *a* by the acetylated cytochrome *c* was decreased slowly in accordance with the progress of the acetylation However, with the succinylated cytochrome *c*'s was observed the rapid decrease of reducibility

Table 1 EFFECT OF CHEMICALLY MODIFIED CYTOCHROME *c*'S ON THE CYTOCHROME OXIDASE ACTIVITY

Sample	NH_2-groups reacted (per cent)	Relative activity (per cent)
Native cytochrome *c*	0	100
	32	0
Acetylated cytochrome *c*	41	0
	71	0
	22	0
Succinylated cytochrome *c*	31	0
	65	0
	49	110
Guanidinated cytochrome *c*	70	116
	90	123

The activity was measured manometrically by using hydroquinone as substrate

When larger quantities of the chemically modified cytochrome *c*'s were added to the reaction mixture containing cytochrome *a* and cytochrome *c*, essentially no inhibition was observed The oxidation of the chemically modified reduced cytochrome *c*'s by cytochrome *a* was further investigated Although the reduced cytochrome *c* was rapidly oxidized by cytochrome *a*, chemically modified reduced cytochrome *c*'s were scarcely oxidized On the addition of a small amount of cytochrome *c* to the reaction mixture, however, the latter was also oxidized rapidly We have attempted to determine the chemical structure of the active site of cytochrome *c* in the cytochrome oxidase reaction, with 2,4,6-trinitrobenzenesulphonate (TNBS) which is known to bind specifically and stoichiometrically with the site related to the enzymatic activity

According to Satake *et al.*[4], TNBS binds only with the amino-groups of proteins at neutral *p*H The specific binding of TNBS with 4 moles of the ε-amino-groups of the lysine residues per mole of cytochrome *c* caused the loss of the cytochrome oxidase activity, although the reducibility on cytochrome *a* was scarcely changed In addition, guanidinated cytochrome *c*'s, which are more basic than naturally occurring cytochrome *c*, even when as much as 90 per cent of the amino-groups were guanidinated,

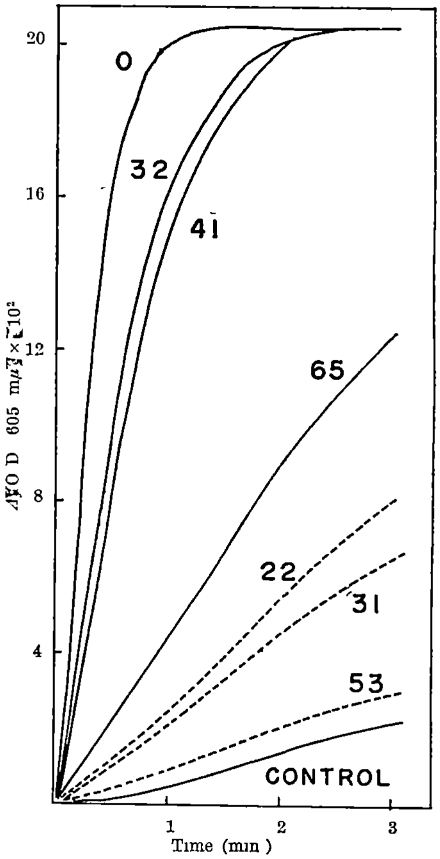

Fig 1 Effect of chemically modified cytochrome *c*'s on the reduction of cytochrome *a*
The assay system (3 ml final volume) contained 9 0 × 10^{-2} *M* phosphate buffer at *p*H 7 4, 1 per cent 'Emasol' 1130, 1 0 × 10^{-3} *M* potassium cyanide, 3 1 × 10^{-5} *M* cytochrome *a*, 1 0 × 10^{-3} *M* hydroquinone, and 1 1 × 10^{-5} *M* cytochrome *c* or a chemically modified cytochrome *c* The percentages shown in the figure represent the extent of modification of the free amino-groups The control shows only the reduction of cytochrome *a* by hydroquinone
——, acetylated cytochrome *c*, – – –, succinylated cytochrome *c*

were as active as the latter in the cytochrome oxidase activity and in the reducibility on cytochrome *a* This is in accord with the data reported by Minakami *et al* [5], who have obtained similar results in the succinic oxidase system of rat liver homogenate

From these results, it may be suggested that some free ε-amino-groups of the cytochrome *c* molecule, which can be easily blocked by TNBS, participate in the cytochrome oxidase reaction with cytochrome *a*, whereas other ε-amino-groups of the molecule, which can be less readily blocked, function in the reduction of cytochrome *a* What is essential for the maintenance of the activity is the positive charges on the lysine side-chains, and it does not matter that these positive charges result from the free ε-amino-groups or from the guanidino groups

Since cytochrome *a* is an acidic protein[6], and cytochrome *c* is a basic protein, the effect of basic proteins on the cytochrome oxidase activity was tested

As shown in Table 2, protamines such as salmine and culpeine strongly inhibit the cytochrome oxidase activity at low concentrations The inhibition was found to be non-competitive with cytochrome *c* However, lysozyme had a less inhibitory effect than did the protamines The synthetic polypeptides which were used here were valuable for demonstrating the interactions between macromolecular basic polyions and cytochrome *a* Poly-L-lysine (polymerization degree, $n = 260$) showed the same inhibitory effect as the protamines However, copoly-1 1-(L-glutamic acid, L-lysine) ($n = 70$) had little inhibitory effect on the cytochrome oxidase activity at low concentration-levels This is not unexpected, since the net charge of the copolymer is zero Furthermore, Nagumo[7] recently reported that the complexes between acidic proteins, such as α-casein and catalase, and basic proteins, such as lysozyme and protamines, were proved by both ultracentrifugal and spectroscopic analyses These results suggest that the inhibitory effect of the basic proteins on the cytochrome oxidase activity depends on the formation of the complex between the acidic protein, cytochrome *a* and any one of the basic proteins

Table 2 EFFECT OF BASIC PROTEINS AND POLYPEPTIDES ON THE CYTOCHROME OXIDASE ACTIVITY

Sample	Concentration (*M*)	Inhibition (per cent)
Salmine	3×10^{-5}	83
	5×10^{-6}	55
Culpeine	3×10^{-5}	80
	5×10^{-6}	54
Lysozyme	3×10^{-5}	20
Poly-L-lysine	3×10^{-5}	70
	5×10^{-6}	52
Co-poly-1 1-(L-glutamic acid, L-lysine)	3×10^{-5}	17

IMMUNOGENIC SUB-CELLULAR PARTICLES OBTAINED FROM SPLEENS OF ANTIGEN-INJECTED MICE

By ROBERT E. FRANZL

The Rockefeller Institute, New York

RECENT work[1,2] has lent new impetus to the concept that the phagocytic activity of the reticulo-endothelial system plays a significant part in antibody synthesis, and that the interaction of antigen and a particular type of phagocytic cell produces the specific factor (the antigenic stimulus) capable of initiating the synthesis of an antibody In the hope of learning more about the nature of the antigenic stimulus, a preliminary investigation was made of the immunogenic properties of an ingested antigen prepared from two highly phagocytic tissues of the mouse prior to the appearance of antibody For this purpose the cell homogenates of spleens and livers from approximately 40 donor mice (Rockefeller Swiss, Nelson-Collins strain), previously injected intravenously with 2×10^8 sheep red blood cells (446 µg nitrogen), were fractionated by differential centrifugation[3] at various time-intervals before the appearance of serum antibody Each of the resulting cell fractions—nuclei, mitochondria, lysosomes, microsomes and supernatants—was then injected intraperitoneally in nine recipient mice, sensitized five weeks previously by an intravenous injection of 2×10^6 sheep red blood cells The ability of the sub-cellular fractions to stimulate a secondary hæmolysin response in the recipient animals was utilized as an assay for immunogenic activity The quantitative hæmolysin titres of pooled sera obtained from three recipients on the fourth, sixth and eighth day after the injection of cell fractions were determined by the method of Taliaferro and Taliaferro[4]

As illustrated in Fig 1, spleen lysosome fractions consistently elicited high hæmolysin titres in sensitized recipient mice The enhanced immunogenic activity of these fractions was also manifested by their ability to induce an antibody response as early as on the fourth day after their administration The other spleen fractions either possessed lower activity (hæmolysin appearing on the sixth and eighth day), or were totally inactive The latter was also true for fractions isolated from spleens of immunized donors at the time of appearance of serum antibody (4 days after immunization) It must be stressed

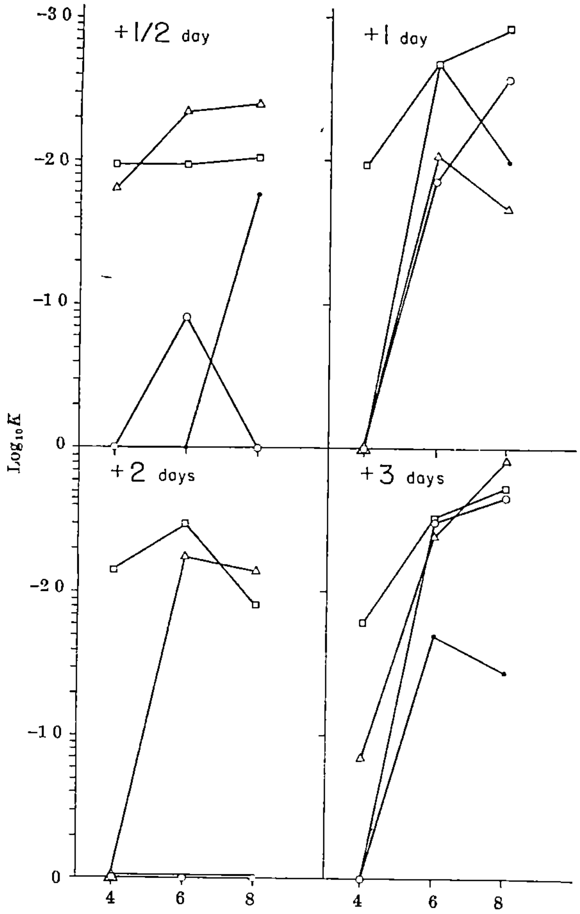

Fig 1 Secondary hæmolysin responses induced by spleen cell fractions from antigen-injected donors Spleen cell fractions, nuclei (*N*, ●), mitochondria (*M*, ○), lysosomes (*L*, □), and microsomes (*P*, Δ) were prepared from donor mice + 1/2, + 1, + 2, and + 3 days after the intravenous injection of 2 × 10^8 sheep red blood cells The fractions were then administered intraperitoneally to sensitized recipient mice which, five weeks previously, had been injected intravenously with 2 × 10^6 sheep red blood cells The dose-ranges (mg N per mouse) were *N* (0 41–2 79), *M* (0 06–0 46), *L* (0 32–0 49), *P* (0 43–0 61) The antibody titres ($\log_{10}K$) of the undiluted sera of recipient mice are expressed as the log of the number of 50 per cent anti-sheep red blood cell hæmolysin units per ml

that, throughout the entire experimental period. all liver cell fractions from antigen-treated donors were completely ineffective in stimulating the secondary hæmolysin response, even though the doses administered contained the same amounts of phagocytized sheep red blood cells present in the active spleen fractions Control experiments with liver and spleen fractions prepared from untreated donor mice were also immunogenically inactive Thus we may conclude that, under the conditions of our experiment, a particulate antigen, sheep red blood cell, after phagocytosis by liver macrophages, loses its ability to stimulate the anamnestic hæmolysin response in mice, whereas its ingestion by spleen macrophages appears to have no deleterious effect on its antibody-stimulating capacity

In the absence of any contrary evidence, the association of immunogenic activity with sub-cellular particles of spleen can be interpreted, in accordance with Straus's findings[5], as probably being due to the presence of contaminating phagocytic vacuoles containing an activated ingested sheep red blood cell antigen

A comparison of the secondary hæmolysin responses elicited by the injection of spleen cell fractions (Fig 1), and the responses evoked by the injection of known amounts of sheep red blood cells into identically sensitized mice, permits the evaluation of the immunogenicity of each administered cell fraction in terms of an equivalent number of sheep red blood cells (Table 1, col 3) These values are only approximate, primarily because cell fractions stimulate an anamnestic response different in character from that obtained with sheep red blood cells alone Nevertheless, the results obtained clearly show that the spleen lysosome fractions had the highest specific and total immunogenicity (Table 1) It is also of interest that the sum of the total immunogenicities of spleen fractions was much higher on the first and third day after the injection of antigen than on the second This effect was found to be reproducible, yet its significance at the present can only be an object of speculation

Table 1 IMMUNOGENICITY OF SPLEEN CELL FRACTIONS AT VARIOUS PERIODS AFTER ANTIGEN INJECTION

(1), (2) For explanation of symbols see legend to Fig 1

(3) The immunogenicity of the injected dose of the spleen cell fractions (Fig 1) is expressed as the number of sheep red blood cells necessary to evoke a comparable secondary hæmolysin response in sensitized recipient mice

(4) Specific immunogenicity is the immunogenicity (column 3) per µg N of the cell fraction

(5) Total immunogenicity is the product of the specific immunogenicity (column 4) and the N content (in µg) of the total cell fraction

From the estimated total immunogenicity of donor spleens (Table 1), and the known distribution of injected foreign erythrocytes in the mouse[6], it can be estimated that only 15 per cent of the antigen phagocytized by the spleen was active in stimulating the secondary hæmolysin response This signifies that no more than 1 5 per cent of the originally administered particulate antigen was immunogenic. These results are in agreement with White's[7] hypothesis that only some of the macrophages of the reticulo-endothelial system of the spleen participate in antibody synthesis

I thank Dr J Primosigh for the nitrogen analysis This work was supported in part by U S Public Health Service grant *E*–3297(*C*1)

PROTON TRANSFER IN NUCLEIC ACID

KYOGOKU *et al* [1] have reported that mixed crystals have been obtained with the nucleoside pairs, adenosine (A)–uridine (U) and guanosine (G)–cytidine (C), and that the infra-red spectra of the mixed crystals show new bands not present in the individual components, indicating a proton transfer from U to A and from G to C (see formulæ (1) and (2) in ref 1)

These experiments were then taken as evidence that certain absorption bands in film spectra of DNA and RNA indicated base pairing by proton transfer[2] The question raised by Kyogoku *et al* [1] is an important one, since it would put the hydrogen-bonding schemes and interchain attractive forces of nucleic acids on quite different bases from those which are usually considered to exist

If the arrangement of bases were that shown in formulæ (1) and (2)[1], the electrostatic attraction between the bases would be expected to account for an important part of the molecular stabilization The hydrogen-bonding schemes presented by Watson and Crick[3] and modified by Pauling and Corey[4] are widely accepted to-day, as is the view of these authors that the hydrogen bonds hold together the polynucleotide chains An increasing understanding of the importance of hydrophobic bonding in biological macromolecules makes it appear likely that this is also an important stabilizing factor (for a discussion of this phenomenon with special reference to the proteins, see, for example, W Kauzmann[5], for a discussion of its importance in DNA see Herskovits *et al* [6])

All the spectra reported here were measured with a Beckman *IR* 7 spectrophotometer, those in Fig 1 as Nujol mulls and those in Fig 2 as deuterium oxide solutions (if the mull and deuterium oxide spectra are compared, it should be borne in mind that the former contain NH_2 deformations which the latter lack, that mull spectra may also contain additional bands attributable to the solid state, and that the frequencies and intensities of bands usually vary with the medium in which they are measured Adding further to the difficulty of interpreting solid-state spectra are the possibilities that different polymorphs of the same compound may have different spectra and that extraneous bands may result from water that is adsorbed or incorporated into the crystal) The samples of pairs of nucleotides were prepared in two ways (*a*) equimolar amounts of nucleosides were thoroughly mixed by brief vibration in an electrically driven agitator (Fig 1, *C* and *G*), (*b*) equimolar amounts of nucleosides were dissolved in water and slowly evaporated to dryness in a desiccator (Fig 1, *D* and *H*) The deuterium oxide solutions of the nucleosides and polynucleotides were prepared and measured in fixed cells of 25μ path-length, solvent compensated, as described in earlier papers[7] The results are given in Figs 1 and 2 and Table 1 (The report[1] that UC and AG also formed mixed crystals with new absorption bands, indicating proton transfer prompted analogous experiments with these pairs The only bands observed in these experiments were those present in the component nucleosides)

The nucleosides were obtained from Pabst and from the California Corporation

Table 1 INFRA-RED SPECTRA IN DEUTERIUM OXIDE SOLUTION

Material	Frequency (cm^{-1})
Cytidine	1,650 , 1,618
Cytidine, *p*H 2	1,712 , 1,657 , 1,591
Inosine	1,673
Inosine, *p*H 12	1,597 1,563
Poly I	1,677
Poly C	1,653 , 1,617
Poly (I+C)	1,697 , 1,648 , 1,630 (sh)

The essential points made by Kyogoku *et al* [1] regarding the solid-state spectra of the nucleosides may be summarized (*a*) neither A nor U has a band at 1,700 cm^{-1}, whereas the mixed crystal AU does have a band at this frequency, similarly, GC has a band at 1,720 cm^{-1} which the separate nucleosides lack, (*b*) the acid forms of A and C have higher frequency bands (compared with the neutral molecules) at 1,693 cm^{-1} and 1,725 cm^{-1}, respectively, (*c*) these higher frequency bands in the mixed crystals are an indication of protonation of the bases by proton transfer

Regarding these points, the following observations are made (*a*) It may be seen in Fig 1 that uridine has a band at 1,698 cm^{-1} and guanosine has a band at 1,732 cm^{-1}, and that the nucleoside pairs, whether obtained by mechanical mixing or by evaporation from aqueous solution, do not differ in any major way from a summation of the appropriate members of the pairs measured separately (though the resolution of some bands of the evaporated mixtures is poorer, no new bands appear) (*b*) The protonated forms of cytidine and adenosine do have new bands at higher frequencies[7-9] (*c*) There is no need to assume proton transfer to explain bands

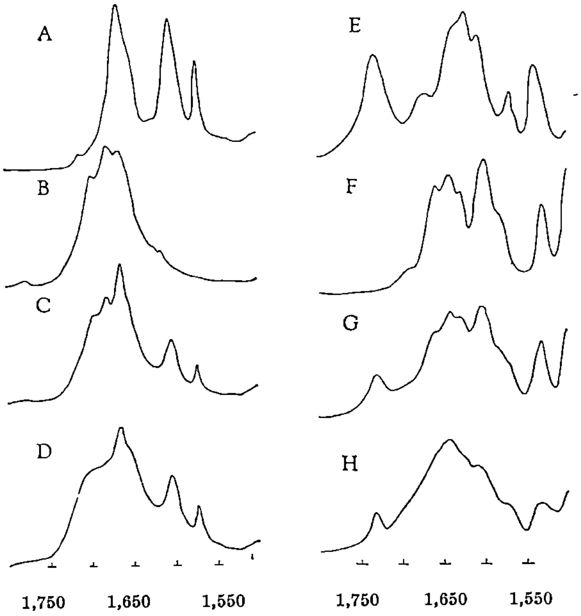

Fig 1 Infra-red spectra of Nujol mulls of the following nucleosides and nucleoside mixtures *A*, adenosine , *B*, uridine , *C*, adenosine + uridine, mechanical mixture , *D*, adenosine + uridine, evaporated from solution , *E*, guanosine , *F*, cytidine , *G*, guanosine + cytidine, mechanical mixture , *H*, guanosine + cytidine, evaporated from solution

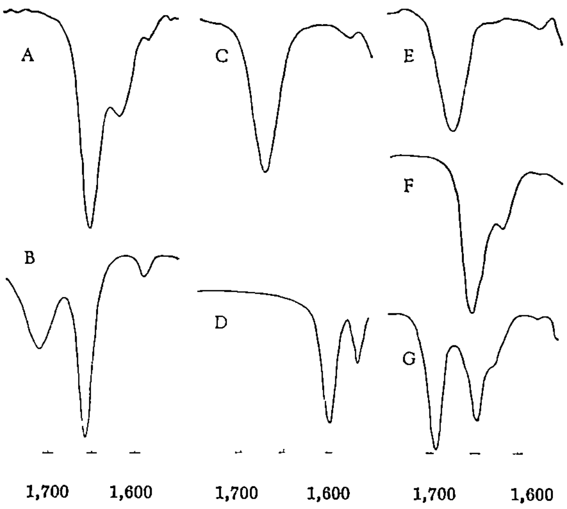

Fig 2 Infra-red spectra of deuterium oxide solutions *A*, cytidine, *B*, cytidine, acid solution, *C*, inosine, *D*, inosine, basic solution, *E*, polyinosinic acid, *F*, polycytidylic acid *G*, interaction product of poly I and poly C (poly (I + C))*

which are present in the individual nucleosides (It is possible that the conditions used here for obtaining the mixed nucleosides from solution do not duplicate those of the paper in question[1], since no experimental details were given This possibility is immaterial, however, in view of point (*c*)

While these observations do not appear to be consistent with the cited[1] basis for expecting proton transfer in nucleic acids, they do not prove that it does not in fact occur in these macromolecules Evidence on this point can, however, be provided by a study of DNA-like[10,11] polynucleotide helices, the example of the interaction product of poly I and poly C (poly (I + C)) being chosen in the present case because of the clear resolution of the bands[7,12] If proton transfer from poly I to poly C occurred, then the hypoxanthine units would exist as anions and have a spectrum similar to that of a basic solution of inosine (Fig 2*D*), and the cytosine units would exist as cations having spectra similar to that of acid cytidine (Fig 2*B*) Proton transfer in this helix would thus require strong bands near 1,710 cm $^{-1}$ and 1,597 cm $^{-1}$, with a band of moderate intensity near 1,563 cm $^{-1}$ (Fig 2, Table 1)[12] Since none of these bands is present, it follows that this kind of proton transfer does not occur, and that the infra-red spectral changes occurring on polynucleotide helix formation must arise from other causes. (Though there would be some overlapping of pertinent bands in the helical interaction product of poly A and poly U (poly (A + U)), the same conclusion can be reached in this case (for spectra see ref 7) Thus, the high-frequency band of uridine would be absent in the anionic[8] form, whereas it is actually observed at 1,695 cm $^{-1}$ in poly (A + U)[7] The 1,666 cm $^{-1}$ band of protonated adenosine would probably be obscured by the 1,672 cm $^{-1}$ uridine band, the neutral adenosine band would be absent, whereas a band reasonably assigned to this source is observed at 1,637 cm $^{-1}$ (ref 7) The spectra[13] of the helical interaction products[14] of poly A and poly I (poly (A + I) and poly (A + 2I)), also rule out the possibility of proton transfer Thus poly (A + I) has a strong inosine band at 1,682 cm $^{-1}$ and a strong poly A band at 1,628 cm.$^{-1}$ If the proton had been transferred from the inosine to the adenosine rings there would be bands near 1,666 cm $^{-1}$ and 1,600 cm $^{-1}$, whereas no absorption is observed near either of these frequencies The same conclusion may be reached from poly (A + 2I) which has a strong band at 1,681 cm $^{-1}$ and a weak one at 1,627 cm $^{-1}$ and no absorption near 1,666 cm $^{-1}$ or 1,600 cm $^{-1}$)

[14] Rich, A, *Nature*, **181**, 521 (1958)

In our previous article[1], we presented a view that a band at 1,710 cm $^{-1}$ of nucleic acids is to be assigned to the adenine–uracil (or thymine) and guanine–cytosine specific base pairings in their secondary structures, in which a proton transfer of the type given in formula (1)[1] and (2)[1] occurs

By later work, a number of experimental facts have been found which show that the 1,710 cm $^{-1}$ band is certainly characteristic of the secondary structure of nucleic acids[2,3]. Thus, drying, heating (for 10 min at 100° C), treating with deoxyribonuclease (for 10 min at 37° C) or treating with formamide causes a marked decrease in intensity of the 1,710 cm $^{-1}$ band of DNA On the other hand, as to what scheme in the secondary structure is responsible for the appearance of the 1,710 cm $^{-1}$ band, our view is still open to question In the preceding communication, H Todd Miles has dealt with this point

In order to obtain information on the specific base pairings, we have further studied the mixed products of adenosine and uridine, and found a few different modifications of the 50–50 per cent products A crystalline product is obtainable from equimolar aqueous mixture of adenosine and uridine by a slow evaporation in a desiccator (The infra-red spectra shown in Fig 1*a* and *b* are apparently different from those given by Todd Miles These differences might come from different experimental conditions both in the procedures of preparing samples and of measuring spectra We used a Perkin–Elmer 112*G* single-beam, double-pass spectrophotometer with a 75 lines/mm grating and a potassium bromide fore-prism In the spectral region in question, atmospheric water

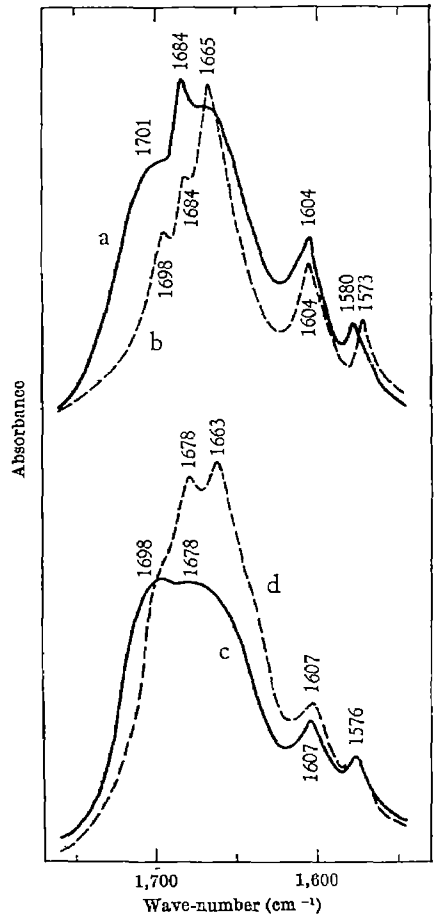

Fig 1. Infra-red spectra of Nujol mulls· *a*, A product obtained from an equimolar aqueous mixture by slow evaporation in a desiccator, *b*, an equimolar mechanical mixture of crystalline adenosine and crystalline uridine powder, obtained from a commercial source (Nutritional Biochemicals Corp), *c*, a product obtained from an equimolar aqueous mixture by quick lyophilization, *d*, an equimolar mechanical mixture of adenosine and uridine powder each of which was obtained by quick lyophilization separately from each aqueous solution

vapour (at 40 per cent relative humidity) seriously interferes with the observation, and therefore extremely dry air (water pressure 5×10^{-3} mm mercury) was flushed into the spectrometer) This gives an infra-red absorption spectrum (Fig 1*a*) and an X-ray powder diagram different from those of the 50–50 per cent mechanical mixture of adenosine and uridine crystals obtained from a commercial source (Nutritional Biochemicals Corp , Cleveland 28, Ohio) (see Fig 1*b*) (The X-ray examination was kindly made by Dr Y Iitaka) An amorphous product is obtained from the similar aqueous mixture by quick lyophilization What we mentioned in the previous article[1] was this amorphous product The words "complex crystal" we used were not correct This gives an infra-red absorption spectrum (Fig 1*c*) different from the crystalline product (Fig 1*a*) and also from mechanical mixtures (Fig 1*b* and *d*) As may be seen in Fig 1, both these products from the aqueous mixture give absorptions in the 1,710 cm^{-1} region. Especially in the case of the amorphous product (Fig 1*c*) this band is much stronger than those of adenosine–uridine mechanical mixtures Thus, a support of our view does still exist here

On the other hand, a few facts have been found which are apparently less favourable for our view None of them, however, is found to contradict seriously with it

In deuterium oxide solution, 1 1-complex of polyadenylic acid and polyuridylic acid shows a 6μ-region spectrum[4] which is not the same as the spectral sum of the protonated adenosine and deprotonated uridine[5] (Fig 2) This fact shows that in this complex the adenine residue is not exactly the same form as that it takes in acidic solution of adenosine, and that the uracil residue is not exactly the same as that it takes in alkaline solution of uridine However, in our model[1] the base residues are involved in a strong hydrogen bond even after the proton transfer takes place Therefore, the electronic states of the residues should not necessarily be the exact duplicates of those of protonated and deprotonated nucleosides freely moving around by themselves in solutions A similar statement may be valid for the 1 1-complex of polyinosinic acid and polycytidylic acid, mentioned by Todd Miles in the preceding communication

Solid-state guanosine was found to take two modifications[5], namely, form (I) and form (II) Form (I) does not give any definite band above 1,700 cm^{-1}, while form (II) gives a strong band at 1,736 cm^{-1} (The modification previously named form (I) was recently found not to be a crystal but an amorphous form The infra-red spectrum of the complex product of guanosine and cytidine observed by Todd Miles is practically the same as that which we observed[1] Both show a band near 1,730 cm^{-1} The apparent difference is that he observed this

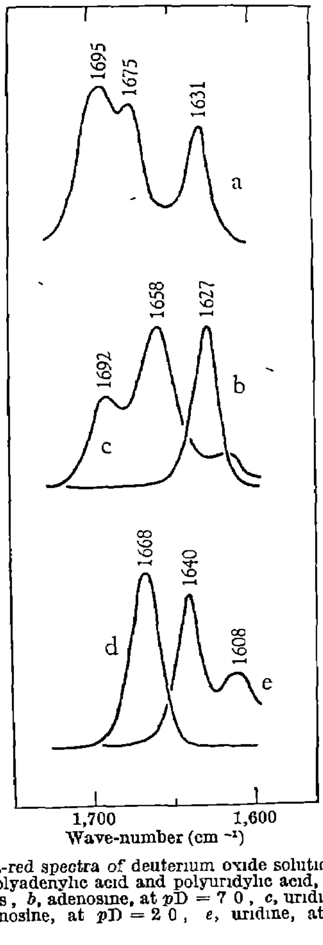

Fig 2 Infra-red spectra of deuterium oxide solutions *a*, 1 1 complex of polyadenylic acid and polyuridylic acid, observed by H Todd Miles, *b*, adenosine, at *p*D = 7 0, *c*, uridine, at *p*D = 7 0, *d*, adenosine, at *p*D = 2 0, *e*, uridine, at *p*D = 11 0

band also in guanosine and we did not This difference comes from the fact that there are two modifications of guanosine By comparison with the spectra given in our later paper[5], what Todd Miles observed is identified as that of form (II), and what we first observed[1] was that of form (I)) This means that guanine residue by itself can give 1,736 cm^{-1} in certain circumstances Polyadenylic acid film obtained from an aqueous solution of *p*H 4 5 shows a strong band at 1,710 cm^{-1} (refs 6 and 7). This band seems to be characteristic of the secondary structure of this polymer, and it disappears on drying the film On deuteration, the 1,710 cm^{-1} band disappears In the deuterated film, no band is observed in the 1,600–1,750 cm^{-1} region the intensity of which is lowered on drying the film Then, the 1,710 cm^{-1} band, in this case, should be assigned to the scissoring vibration of the strongly hydrogen-bonded NH_2 group or strongly bound water molecule These facts suggest that, in the assignment of the 1,710 cm^{-1} band in nucleic acid (for example, ribonucleic acid), not only the specific base pairings but also other factors (such as non-specific base–base interactions) should be taken into consideration

In conclusion, our models, (1) and (2), still remain as one of the possible explanations of the 1,710 cm^{-1} band, although the critical evidence has not yet been established Conclusive assignment of this 1,710 cm^{-1} band will be made on the basis of a quantitative work of the normal modes of vibrations of the base residues, which is now in progress

SOME ELECTRICAL PROPERTIES OF THE MEMBRANE OF A CELL NUCLEUS

By PROF WERNER R LOEWENSTEIN and DR YOSHINOBU KANNO
Physiology Department, Columbia University, College of Physicians and Surgeons, New York

THE past fifteen years, since Graham and Gerard[1] and Ling and Gerard[2] introduced the microelectrode, have seen a considerable increase in our knowledge of the electrical properties of the cell membrane Membranes of a great variety of cells have been studied The studies, however, have been limited to the plasma membrane Membranes of cellular organelles such as the nucleus, although they are the sites of the passage of materials of particular biological importance, have not yet been examined The reasons for this neglect are not difficult to find Cells are small and nuclei are even smaller The size of most nuclei places them beyond the reach of the microelectrode Besides, electrophysiologists traditionally have devoted little attention to membranes other than 'excitable' ones where large electrical changes occur during activity There are, however, a few animal cells with nuclei large enough for electrophysiological work An example is the salivary gland cell of the fruit fly (*Drosophila*) larva In a large gland cell, the nucleus measures 30–40μ in diameter The nucleus can be viewed *in vivo* without staining aids under an ordinary microscope Its surface[3], like that of other nuclei[4–11], appears as a double-layered membrane under the electron microscope and presents mechanical properties distinctly different from those of the cytoplasm and nucleus interior on micromanipulation[4,12,13] This article deals with some electrical properties of this membrane It will be shown that the nuclear membrane has a high electrical resistance and capacitance, and that there is a potential across it which is of about the same magnitude and sign as that across the cell membrane

Nuclei of salivary gland cells of *Drosophila flavorepleta* larvæ (third instar) were used in the experiments These nuclei do not divide during the third instar stage The glands were isolated and mounted in a bath of Schen's solution The cells of freshly obtained gland cells are quite transparent The nucleus, its outline and some of its internal details are clearly seen under a phase contrast or dark field microscope Electrical measurements were made with microelectrodes (3 *M* potassium chloride) of tip diameters below 0 5μ and tip potentials below 2 mV (ref 14) Such electrodes could usually be inserted into the cell and nucleus a few times without apparent change in membrane potential Two electrodes were inserted into each nucleus or cell with the aid of a pair of micromanipulators (Fig 1) One electrode served to pass square pulses of current of measured intensity across the membrane, the other to record the resulting passive potential, and the 'resting' potential Potentials were fed into the d -c amplifier of an oscilloscope through a cathode follower with a variable negative capacitance The passive potential had an exponential time course The membrane resistance was calculated from the 'steady state' potential, and the capacitance from the time constants of the rising or falling phase of the potential The nucleus is nearly spherical, its membrane area could thus be measured with a high degree of accuracy

Fig 2 illustrates an experiment in which the cell and its nucleus were successively impaled with a potential measuring electrode As the electrode is advanced from the cell exterior towards the nucleus one finds (1) an abrupt change in potential as the

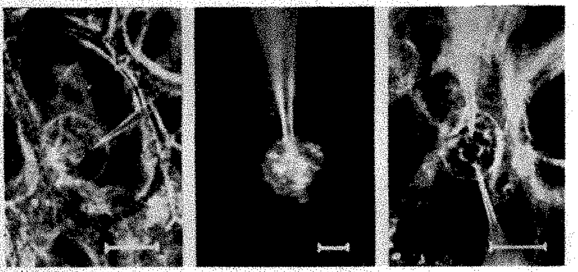

Fig. 1. Dark-field photomicrograph of unstained, fresh salivary gland cells. Views of nuclei impaled *in situ* with one (left) or two microelectrodes (right); or in semi-isolation after destroying mechanically the cell membrane (centre, the portion of cytoplasm that adheres to and surrounds the nucleus is not visible in this photomicrograph). (Calibration 25μ)

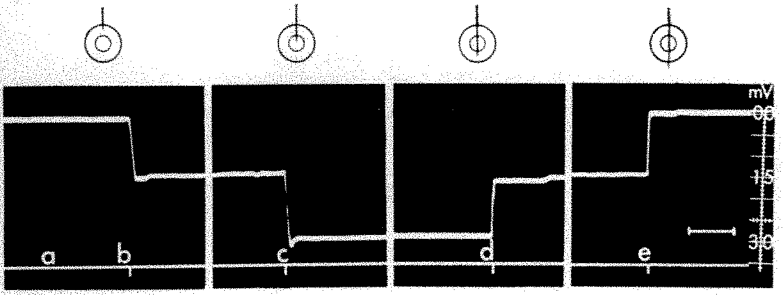

Fig. 2. Potentials across cell and nucleus membranes. A micro-electrode is advanced progressively in the direction of cell exterior-nucleus. Upper beam records the potential (downward deflexion negative) as the electrode tip is *a*, outside the cell; *b*, penetrates the cell membrane; *c*, enters the nucleus; *d*, leaves the nucleus and enters again into the cytoplasm; *e*, emerges into the cell exterior. Reference electrode is in the solution bathing the cell exterior. Time calibration: 0·05 sec., film interrupted for about 1 sec. in between photographs

electrode penetrates the cell membrane; (2) no further change in potential as the electrode moves through the cytoplasm; (3) another abrupt change in potential when it enters the nucleus. The latter change occurs clearly at the surface of the nucleus. It is associated with the penetration of the electrode tip into the nucleus and is preceded by a visible dimpling of the nucleus surface. No change in potential is seen, as the electrode tip moves through the interior of the nucleus.

The mean potential across the cell membrane of 25 cases was 12 mV. with a standard error of ± 0·7 mV. (cytoplasm negative). This is about 10 mV. lower than the cell membrane potential of mammalian salivary gland cells (type I)[15]. The mean potential between the nucleus interior (negative) and the cytoplasm (hereafter referred to as nucleus membrane potential) was 13 ± 1·1 mV. (18 cases): and the total potential between nucleus interior and cell exterior was 25 mV.

The surface of the nucleus has a high electrical resistance. When the current delivering electrode is inside the nucleus, and the potential recording electrode is advanced from the cytoplasm into the nucleus, one measures a sharp increase in resistance on penetration into the nucleus. The increase in resistance coincides with the appearance of the nucleus membrane potential. It is clearly associated with the nucleus surface: as the electrode moves through the nucleus interior, changes in resistance are several orders of magnitude lower than at the surface. The resistance that appears to be associated with the nucleus boundary will here be referred to as nucleus membrane resistance. Table 1 gives resistance values of seven representative nuclei. Typically the nucleus membrane shows no rectification; its resistance is constant over a wide range of inward or outward currents (Fig. 3). Moreover, it gives no sign of excitation over the entire range of current that can be used without destroying the membrane. This applies to the nucleus both semi-isolated and *in situ*. The mean nucleus membrane resistance was 1·5 ± 0·4 Ω cm.^{2} and the capacitance 412 ± 62 μF./cm.^{2} (8 cases). Resistance and capacitance were measured in each case under two different conditions: first, in the nucleus *in situ*, surrounded by the cytoplasm and the 'intact' cell membrane (the resistance and capacitance of the cell membrane were previously measured, and the nucleus and cell membranes were treated as leaky capacitors in series); and then, in the semi-isolated nucleus, immediately after rupturing the cell membrane, and thereby eliminating completely the cell membrane resistance and capacitance, the nucleus being still completely surrounded by a mass of cytoplasm. There was, in most cases, fair agreement between the values obtained under the two conditions.

The capacitance of the nucleus membrane is high compared with that of the cell membrane. This result will be discussed in a future paper. The resistance, on the other hand, is smaller than that of the cell membrane (Table 1). It is also smaller than that of the cell membrane of a number of other cells[16-21]. It is, however, large enough to indicate that the nuclear membrane must be a formidable ion barrier. In this connexion it is interesting to consider some recent electron microscope studies which picture the nuclear membrane with large pore-like structures, 400–1000 Å. in diameter[3-10]. From the present results it appears that these 'pores' cannot provide a direct contact between the nucleo- and cyto-plasm. On the basis of a pore diameter of

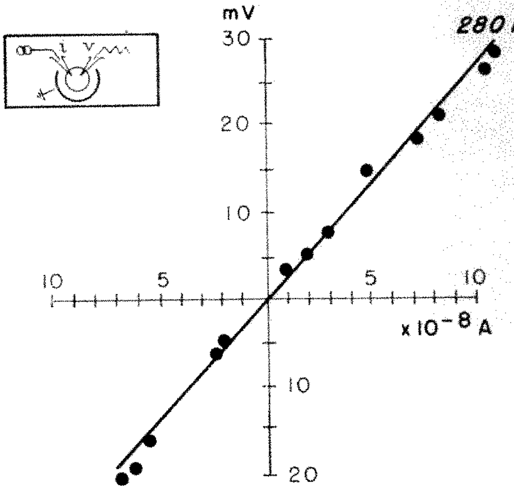

Fig. 3. Current-voltage relation in a nucleus membrane. Square current pulses of 24 msec. duration are passed through the membrane of a semi-isolated nucleus with one microelectrode (*i*) and the corresponding electrotonic potentials are recorded with a second microelectrode (*v*). Abscissæ, total nucleus membrane current, inward current left (membrane area = 1·6 × 10^{-5} cm.^{2}); ordinates, steady-state electrotonic potential, hyperpolarization downwards

† Capacitance values as calculated from time constants of the apparent reactance term of membrane impedance.

500 Å., a spacing of 1500 Å. in between pore centres, a total membrane thickness of 200 Å.[3] and a resistivity of 50 Ωcm. for nucleoplasm and cytoplasm, it is calculated that the nucleus surface exposed to the cytoplasm would be 15–23 per cent and that such a perforated membrane would have a resistance of 7×10^{-4} to 4×10^{-4} Ωcm.^{2}, a value four orders of magnitude lower than the observed one. It would seem, therefore, that the 'pores', which have often been associated with the passage of large molecules through the nucleus membrane, are either not freely communicating fenestrations, or that the material within them is of very high resistivity.

We thank Prof. G. Hoecker, University of Chile, for pointing out the salivary gland of the fruit fly as a convenient material for our investigations, and Prof. T. Dobzhansky, Columbia University, for kindly providing us with the specimens which started out our fly colony. We also thank the National Cystic Fibrosis Research Foundation, the National Science Foundation, and the National Institutes of Health for financial support.

ADAPTATIONS OF THE MAMMALIAN SKIN TO THE AQUATIC MODE OF LIFE

By DR. W. SOKOLOV
Department of Vertebrate Zoology, University of Moscow

THE aquatic mode of life is natural to various mammals. The degree of their adaptation to an aquatic medium varies. It is possible to establish a number of transitory forms from almost exclusively terrestrial to purely aquatic ones. The main function fulfilled by the cutaneous covering of aquatic mammals, when they are in water, consists in providing the thermo-insulation of the organism, which is explained by a high degree of heat conduction of water exceeding many times that of air. Among its other functions are: ensuring heat delivery; protection of the organism against mechanical injuries; facilitation of gliding of the body in water when swimming and so on.

A thick-haired animal, when in water, still retains an air layer in its pelage, which serves as a heat insulator. However, in mammals leading an exclusively aquatic mode of life such an air layer cannot remain, for in case of the slightest mechanical action on their fur it would be disturbed, and to restore it the animal would be compelled to return to dry land. Being unable to fulfil its chief function, that is, heat protection, the pelage of such mammals becomes reduced. Instead, a subcutaneous layer of fat tissue is developed of such a thickness which is never found among land animals leading an active mode of life. In hibernating species, an equally thick fat tissue develops before hibernation commences. Yet, this fat content in hibernating animals changes sharply according to season, its function consisting rather in the accumulation of food reserves than in the preservation of heat in the organism. On the other hand, in purely aquatic forms the fat tissue undergoes but slight alterations during the course of the year. Investigations carried out by Scholander *et al.*[1] have shown that when the animal is in water its subcutaneous fatty layer proves to be a much better thermo-insulator than the air layer in its fur. Thus, the impossibility on the part of strictly aquatic animals to keep an air layer in their pelage and, on the other hand, higher thermo-insulating properties of subcutaneous fat than those of that layer, have determined this trend of the evolutionary process. A definite economy is brought about in those animals owing to their large dimensions corresponding to a relatively small body surface.

Amphibian mammals of moderate size, which spend a considerable time on dry land, do not follow

Table 1 HAIR PECULIARITIES OF SEMI-AQUATIC AND SOME OF LAND MAMMALS

Species	Correlation of axes of the axial hair cross-section	No of kinks in		Breadth of the medullary layer of an axial hair in per cent to its whole breadth
		axial hairs	wool hairs	
Ornithorhynchus anatinus	1 6	absent	4	16
Tachyglossus aculeatus	1 3	1 5–2	absent	absent
Chironectes minimus	1 3	2–3	5–6	57
Neomys fodiens	1 2	3	2–3	50
Sorex araneus	1 2	1–1 5	1–2	58
Galemys pyrenaicus	1 3 6	3–4	4–5	absent
Desmana moschata	1 4	3–4	7–8	,,
Talpa europaeus	1 1 5	3	3	60
Lutra lutra	1 2 3	absent	5–6	58
Mustela lutreola	1 2	,,	1–2	66
Martes martes	1 1 7	,,	3	85
Marmota baibacina	1 2 5	,,	3–5	92
Castor fiber	1 2 3	,,	7	46
Microtus arvalis	1 3	,,	3–5	92
Ondatra zibethica	1 2 6	,,	4–5	57
Arvicola terrestris	1 2	,,	2–3	75
Myopotamus coypus	1 2 5	,,	5–7	76

the path of fur reduction On the contrary, their pelage is highly developed Scholander *et al* [1] indicate that the subcutaneous cellular tissue is a thermo-insulator of poor efficiency in the air medium Thus, a layer of blubber in the seal is little more efficient in its insulating properties than the skin of the lemming notwithstanding its much greater thickness Therefore, with a reduced pelage, the animal would need a very thick layer of subcutaneous fat to ensure reliable heat protection in the air, this would impair its mobility on dry land It is natural that all mammals forced by their nature to move swiftly on dry land, for example, all beasts of prey, cannot possess a thick layer of subcutaneous fat On the other hand, the thickness of the subcutaneous cellular tissue is in contradiction with the animal's dimensions The smaller the latter, the relatively thicker should be the fat tissue (a relative magnitude of heat delivery is found to increase in animals of small size). Mammals rather slight in build such as the duck-bill or musk-shrew which on principle could develop a subcutaneous fat tissue instead of a pelage fail to do so because that tissue would be necessarily so comparatively thick, much thicker than, for example, in the seal, that it could not be formed in a small animal

According to the character of their cutaneous covering aquatic animals which I have examined may be divided into two groups (1) semi-aquatic forms with a dense pelage (*Ornithorhynchus anatinus, Chironectes minimus, Neomys fodiens, Galemys pyrenaicus, Desmana moschata, Lutra lutra, Mustela lutreola, Castor fiber, Ondatra zibethica, Arvicola terrestris, Myopotamus coypus*), (2) animals more adapted to life in water or even purely aquatic ones with a well-developed subcutaneous fat tissue The second group may be divided into two sub-groups (*a*) animals with a pelage at different stages of reduction (*Callorhinus ursinus, Eumetopias jubatus, Odobaenus rosmarus, Phoca vitulina*), (*b*) those which are devoid of hairs (*Eubalaena glacialis, Balaenoptera physalus, B borealis, B acutorostrata, Physeter catodon, Berardius bairdii, Delphinus delphis, Lagaenorhynchus obliquidens, Orcinus orca*)

The hairs of group (1) may be distinctly subdivided into the categories directing, axial and wool hairs Even in Insectivora (in *N fodiens* and particularly in *G pyrenaicus* and *D moschata*) these three types of hairs sharply differ from each other, while in terrestrial species of this order, for example, in members of the genus *Sorex*, wool and axial hairs are alike The latter are broader in semi-aquatic mammals (Table 1) Wool hairs of aquatic species have a large number of kinks (Table 1)

These wool hairs are relatively less thick Thus, in the small *Sorex araneus* and in the much larger *D moschata* the thickness of wool hairs is the same, that is, 0 015 mm The difference in length between wool and axial hairs of semi-aquatic animals is greater than in terrestrial forms For example, in *S araneus* and *S minutus* these hairs are nearly equal, but in *D moschata* axial hairs are 2–5 5 mm longer than wool hairs In most axial hairs the thick part, the so-called granna, rises over the wool hairs, and at its base the hair forms a kink In the structure of hairs of semi-aquatic species a slighter development of the medullary layer is characteristic (Table 1), which makes hairs more solid and flexible in swimming, due to that fact their specific gravity approximates 1 In *D moschata* the medulla of the wool hairs is half as thick as that of *N fodiens* and a third as thick as that of *Sorex araneus* Hairs of semi-aquatic animals form well-marked tufts and groups They are present even in *G pyrenaicus* and *D. moschata*, although in all terrestrial Insectivora and in *N fodiens* (less adapted to aquatic life) the hairs are located singly The tufts produce a denser fur Hairs of semi-aquatic species surpass in thickness those of most terrestrial animals Thus, the number of hairs per 1 cm^2 of skin reaches in *S araneus* 15,000 on the back and 14,000 on the abdomen, in *N fodiens* 16,000 and 15,000, in *D moschata* 30,000 and 37,000, in *O zibethica* 11,000 and 12,000[2], in *L lutra* 35,000 and 51,000[3] and in *M coypus* 6,000 and 14,000[4] It is characteristic that the abdomen of semi-aquatic animals (contrary to land animals) is protected from cooling by a denser and higher fur The density of the pelage in individuals of semi-aquatic species dwelling in the north and south differs to a much lesser degree than it does in terrestrial forms This peculiarity may be explained by more stable temperature conditions of the water medium in various latitudes Also, in connexion with the fact that the temperature of water, as compared with air, changes less in the different seasons, a slighter seasonal variability of the pelage is noticed

All peculiarities of the hair cover of semi-aquatic animals (dense fur, high and broad axial hairs, slight development of the medullary layer) allow the retention of an air layer while swimming In this case the dilated upper parts (grannas) of axial hairs, rising over the down, bend parallel to the body surface and cover the down Owing to the surface tension of water ends of these hairs, forming a T-shaped covering, keep the air in the underfur Kinks in wool hairs increase their resilience and they probably do not allow for the pressure of water in diving to reduce the thickness of the air layer in the fur

In amphibian mammals the thickness of skin, epidermis and dermis is as a rule greater on the abdomen than on the back, which is the reverse of terrestrial species No differences are present in the structure of the epidermis A stronger development of the papillary layer characterizes the dermis in the skin of semi-aquatic animals Bundles of collagen fibres mostly form a lax type of plexus The subcutaneous fat tissue is either poorly developed or even quite absent Sebaceous and sweat glands are usually large The giving off of excess heat when the organism becomes overheated is accomplished in water mostly by parts of the body with no pelage In the majority of semi-aquatic forms the tail serves as such a site for giving off excess heat It is usually of large dimensions with few hairs or without them, but with a well-developed blood system In air, surplus of heat is given off by evaporation of sweat in most species or, evidently, at the expense of breathing if the sweat glands are absent, as, for example, in *M coypus*

Animals with a pelage in the state of reduction (sub-group *a* of the second group-order Pinnipedia) are as a rule more adapted to aquatic life than those of the first group Their hairs may be divided into axial and wool, but the former have no characteristic grannas, while the latter are of the same form as the axial hairs They lose their function of creating an air layer, when the animal is in water Probably their main task consists in protecting the body surface against mechanical injuries and in promoting movements on the ice, as, for example, in seals The animal covered with such a fur can easily glide over the snow or ice, and at the same time elastic hairs prevent its rolling back The hairs in animals of the second group sharply decrease in length, but increase in breadth, the number of hairs being reduced, but the hairs still grow in tufts The M m arrectorus pilorum is absent New-born cubs of seals with little-developed subcutaneous fat tissue have a dense pelage with well-marked wool hairs The cubs do not swim at that time With the beginning of an aquatic mode of life accumulation of fat begins under their skin and the juvenile pelage is replaced by adult fur

In animals of that sub-group the epidermis becomes considerably thicker In most cases all the five layers may be found therein, the corneous layer being particularly well developed In the walrus the epidermis reaches its greatest thickness and has an alveolar structure on its inner surface In this mammal is the greatest reduction of hair cover among Pinnipedia and here only its epidermis protects the organism against mechanical action The dermis is much thickened, the reticular layer forming the greatest part Bundles of collagen fibres form intricate plexuses In the dermis there is a specific net of smooth muscle bundles unconnected with hairs Probably these muscles can change the configuration of the skin contour in swimming and make the folds, which probably have an anti-turbulent function The elastic fibre plexuses which are absent in land mammals assist the displaced tissues to return to their usual places I cannot suggest another function for these morphological structures The thermo-insulating function passes to the subcutaneous fat tissue of great thickness Sweat and sebaceous glands are well developed

The densest and highest pelage is found in the fur-seal It is evidently connected with the relatively active mode of life led by the fur-seals on land during summer

Giving off of excess heat in Pinnipedia, in the case of their becoming overheated in water, occurs among sparsely haired species directly from the body surface But in densely haired forms during short immersions, when there remains an air layer in the hairs, it takes place mostly from the surface of flippers In the air medium heat is delivered by sweat evaporation

In mammals leading an exclusively aquatic mode of life (sub-group *b* of the second group-order Cetacea) hairs either completely disappear as, for example, in most Odontoceti, or remain on the snout to serve as tactile vibrissæ (in Mystacoceti) The thickness of the epidermis sharply increases, because now it has to fulfil its main protective function against mechanical actions It has an alveolar structure on its inner surface and its external layers remain uncornified It is necessary to add that the latter property is not a specific feature of the epidermis in animals of the sub-group *b*, but it is characteristic of epithelial coverings of some organs in terrestrial mammals Thus, an alveolar structure is natural to the thick epidermis of some hairless parts of the skin, for example, to the soles of human feet The tongue epithelium is likewise alveolar without being always cornified However, in Cetacea the alveoli are distributed in a strictly definite order, and their form is specific for diverse species Perhaps they assist to make small folds (see, for example, F S Essapian, 1955, Pl 8, 9) which may be have an antiturbulent function Large skin folds (F S Essapian, 1955, Pl 3, 5) (also antiturbulent ?) probably are formed by the subcutaneous muscles The dermis of Cetacea is comparatively thin, without being subdivided into layers The bundles of its collagen fibres show usually a complex interweaving The subcutaneous fat tissue, fulfilling the important function of thermo-insulation, occupies the largest part of the skin, being formed by sparsely disposed bundles of collagenic fibres and by an enormous accumulation of fat cells There are no cutaneous glands in Cetacea The giving off of surplus heat is carried out by the whole body surface of the animal and to a relatively high degree by the fins

A change in the chemical composition of the subcutaneous fat in animals belonging to the second group is of interest In most terrestrial species and in semi-aquatic forms of the first group the fat is characterized by a considerable content of saturated fatty acids (fats with a low iodine number) The subcutaneous blubber of Pinnipedia and Cetacea contains a vast number of non-saturated fatty acids (fats with a high iodine number), which provide a low temperature of the fat setting (Table 2) The latter circumstance is of great importance for Pinnipidea and Cetacea, particularly for those inhabiting arctic and antarctic waters because the outer layer of their skin has usually a low temperature only just surpassing that of the surrounding water

Table 2 THE IODINE NO AND THE TEMPERATURE OF THE SUBCUTANEOUS FAT SETTING IN SOME ANIMALS (refs 5, 6)

Species	Iodine No	Temperature of the fat setting (°C)
Phoca sibirica	130–133	+ 3
Balaena mysticetus	69–144	+ 7 to + 9 5
Balaenoptera musculus	99–136	+ 5 to + 8
Balaenoptera physalus	107–155	+ 3 to + 5
Mustela putorius	65	+ 31
Mortes zibellina	57	+ 28 to + 30
Citellus pygmaeus	118	0 to + 2

In hibernating species the subcutaneous fat has also a high iodine number Their temperature during the hibernation is near to the environment Such a chemical composition of subcutaneous fat of Pinnipedia, Cetacea and hibernating animals protects the animals against the setting of external layer of their body

MESSENGER RIBONUCLEIC ACID IN PEA SEEDLINGS

By U E LOENING

Department of Botany, University of Edinburgh

AN unstable ribonucleic acid (RNA) carrying information from deoxyribonucleic acid (DNA) to ribosomes for protein synthesis was postulated by Jacob and Monod on the basis of enzyme induction and other experiments with bacteria[1] The presence of such a messenger RNA could be shown in a number of cases[2–4] It is characterized by a high rate of turnover and by a base composition similar to that of the DNA, uridylic acid taking the place of thymidylic The messenger will also hybridize with its homologous heat-denatured DNA, and naturally occurring hybrids have been found[5,6] The experimental demonstration of the presence of messenger RNA is greatly facilitated under conditions of continued protein synthesis but no net RNA synthesis In this way the turnover of the messenger and its base composition can be studied by radioisotope incorporation without interference due to incorporation into 'bulk' RNA These conditions have been obtained in phage-infected bacteria[2,3] and in 'step-down' cultures[4]

Under normal conditions of growth, however, the messenger RNA must be separated from other RNA components for identification This is partly achieved in bacterial homogenates, from which messenger RNA can be sedimented bound to the ribosomes at a high magnesium ion concentration, and released by lowering the magnesium concentration[3] This technique has been applied in experiments with pea seedlings described here An RNA with a high rate of turnover was detected by its sedimentation with ribosomes at a high magnesium ion concentration, using the centrifugation technique described previously[7] It could be partially separated from the ribosomes by electrophoresis at a low magnesium concentration The structural RNA of the ribosomes themselves remained unlabelled for some time after incubation of the seedlings in radioactive phosphate The base composition of the rapidly labelled RNA could therefore be determined without interference from other labelled RNA components, and was found to be closely similar to the DNA of the tissue The experimental procedure was as follows

Batches of 60 two-day-old pea seedlings were given a 'pulse' incubation by immersing the first centimetre of the 3–4 cm long roots in a medium at 25° containing 1–2 mc carrier-free phosphate labelled with phosphorus-32, 0 1 m*M* magnesium chloride and 0 1 m*M* potassium nitrate at *p*H 6 8 in a total volume of 25 ml This solution was used only once, since it was found that repeated use resulted in a greatly reduced uptake of phosphorus-32 into RNA The addition of the small concentrations of salts was an attempt to prevent this *Tris* buffer also reduced the uptake of phosphate For the 'chase' incubation, the seedlings were transferred to a large volume of 2×10^{-5} *M* phosphorus-31 phosphate at *p*H 6 8, also at 25° After cooling to 0°, 6–7 mm root tips were cut and homogenized in 3 ml medium containing 0·5 *M* sucrose, 35 m*M* *tris* buffer at *p*H 7 4, and 5 m*M* magnesium chloride The larger cell components were removed by centrifuging at up to 30,000*g* and the microsomes sedimented at 140,000*g* for 90 min Vesicular material was removed from the free ribosomes by centrifuging the tubes inverted at about 300*g*, the ribosomes then remain as firm pellets at the tips of the tubes This technique has been described previously[7]

The ribosomes were examined by electrophoresis on cellulose acetate membrane[8,9] using 50 m*M* *tris* buffer at *p*H 7 4 containing 0 1 m*M* magnesium chloride 120 V was applied across 10-cm strips of the membrane at 0° The ribosomes moved about 4 cm in 3 hr The membranes were dried at 0°, washed in 0 5 *N* perchloric acid, rinsed in *tris* buffer and re-dried The strips were then scanned for radioactivity at 1 5-mm intervals, using an automatic scanning device fitted to the Ekco *N664A* scintillation head The position and quantity of ribosomes was determined by scanning the strips at 260 mμ after clearing in 'Ondina oil 17' (Scottish Oils and Shellmex, Ltd) The absorption curve of the nucleoprotein in the oil-cleared membrane is similar to that in buffer

Scans were obtained after various periods of pulse and chase incubations Fig 1 shows the result after a 10 min pulse and 2 min chase The peak on the origin is due to traces of vesicular material, and its relatively high radioactivity reflects the high rate of turnover of the phospholipid The absorption peak shows the position of the ribosomes at about 3 5 cm , but the main radioactive peak has travelled considerably slower and covers a region of relatively little ultra-violet absorption This peak could be entirely removed by incubating the strips moistened with ribonuclease and acid washing This indicates that the activity was due to labelled RNA The phospholipid on the origin remained almost unaffected by ribonuclease treatment This 'pulse-labelled' RNA gradually disappeared during the chase incubation, and it was only after a long chase that the ribosomes became labelled This is shown in Fig 2, where after a 10-min pulse and 50-min chase, the absorption and radioactive peaks are coincident From scans similar to those shown in Figs 1 and 2 the amount of phosphorus-32 incorporated into RNA after various times of incubation was determined This is expressed as total counts per min irrespective of the position of the radioactivity on the electrophoresis strips (but neglecting the phospholipid on the origin) and calculated per unit ultra-violet absorption of the ribosomes and per unit radioactivity of the incubation medium The time course of this labelling during a 10-min pulse and subsequent chase is plotted in Fig 3 The first rise up to 12 min incubation is due to radioactivity migrating slower than the ribosomes as in Fig 1 This is largely removed during the chase incubation The second rise after 50 min. is due to labelling of the ribosomes as shown in Fig 2 At the

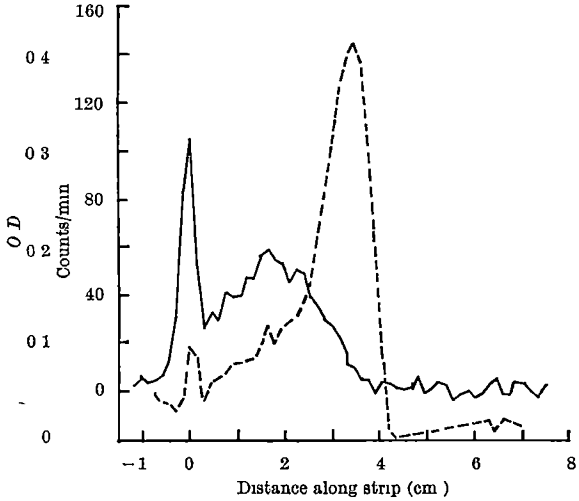

Fig 1 Pulse-labelled RNA associated with ribosomes Seedlings were incubated in ^{32}P (6 34 × 10^{7} counts/min /ml) for 10 min and in ^{31}P (2×10^{-5} *M*) for 2 min Electrophoresis of the isolated ribosomes at 12 V /cm for 2½ hr in 50 m*M tris* buffer at *p*H 7 4, containing 0 1 m*M* MgCl$_2$ Optical density scan (at 260 mμ) of the oil-cleared strip shown by the dotted line and radioactivity scan (counts/min) by the continuous line Readings for both scans were made at 1 5-mm. intervals

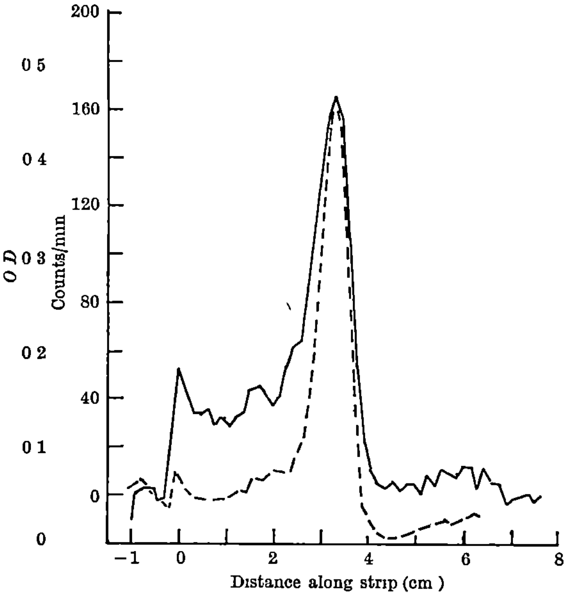

Fig 2 Ribosomal RNA labelled after a long chase. Seedlings were incubated in ^{32}P (1 88×10^{7} counts/min /ml) for 10 min and in ^{31}P for 50 min Electrophoresis as in Fig 1 Dotted line, optical density, continuous line, radioactivity

minimum labelling at 40 min, the pulse RNA and ribosomes each account for about half the radioactivity, as is shown by the double peak in Fig 4 It appears, therefore, that there is a ribonucleic acid fraction sedimented with the ribosomes which is turning over rapidly, so resembling messenger RNA Its detection is unequivocal because of the delay before the ribosomes become labelled It is interesting to note that the amount of radio-phosphorus in the supernatant from which the microsomes had been sedimented rises rapidly during the pulse but does not fall during a 30-min chase Since the phosphate concentration in the chase incubation medium is less than 1 per cent of the intra-cellular phosphate[10], it seems likely that phosphate taken up by the roots is available for metabolism for a short time only and thereafter is taken up into vacuoles or other cell structures Evidence for this has been obtained by electrophoresis of the vesicular fractions, when 3–5 times as much inorganic phosphate is released from the vesicles in citrate buffer as in *tris* buffer containing 0 1 m*M* magnesium ion Ts'o and Sato[10] also found that much of the intracellular phosphate was bound and not available for metabolism If this were not so it would be impossible to chase out the pulse-labelled RNA The effect of repeated incubations in the same solution, and of *tris* buffer, seems

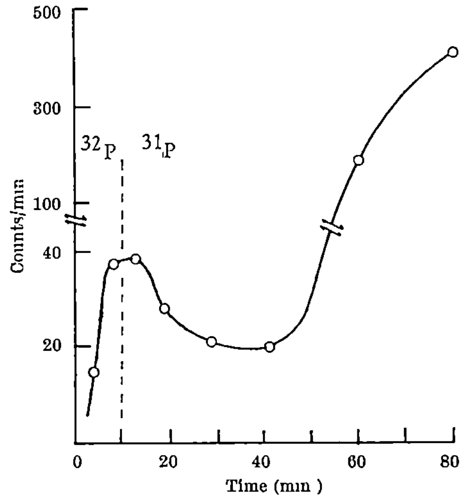

Fig 3 Time course of labelling of ribosomes and associated RNA Seedlings were incubated for 10 min in ^{32}P and then in ^{31}P, as indicated Values of radioactivity of RNA per unit ribosomal ultra-violet absorption were obtained from scans similar to those in Figs 1, 2, and 4, neglecting the peaks due to phospholipid on the origins

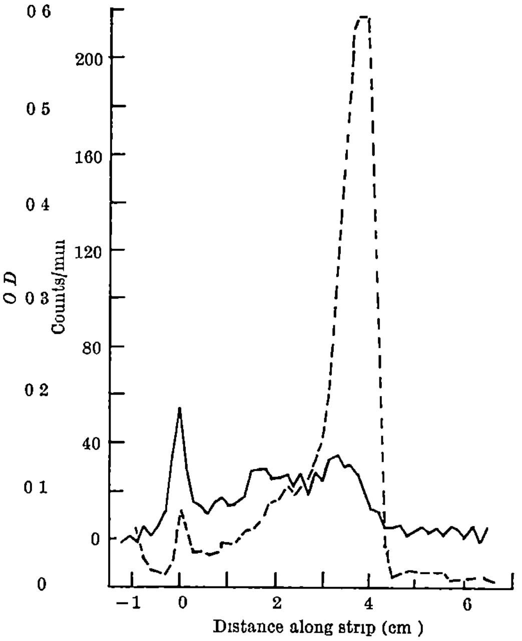

Fig 4 RNA labelled after a chase of intermediate length Details as in Fig 1, except the incubation in ^{31}P, which was for 31 min Dotted line, optical density, continuous line, radioactivity

to be to reduce the amount of metabolically available phosphate rather than its total uptake

Electrophoresis of the vesicular microsome fractions releases some ribosomes, but little or none of the pulse-labelled RNA was found There was, however, some leakage of acid-insoluble labelled substances from the highly radioactive phospholipid peak on the origin and this may have obscured the results The insoluble material on the origin does contain some labelled RNA, but this has not yet been obtained sufficiently pure to measure its specific activity or its base composition It is not known whether any of this RNA includes the ribosome precursors, or in which cell fractions these precursors occur during the first 40 min incubation The membrane-associated ribosomes do not become labelled sooner than free ribosomes

In order to determine the base composition of the labelled RNA by the radioactivity of the nucleotides after alkaline hydrolysis, it was necessary to free the RNA from traces of other radioactive materials, and considerable difficulty was experienced in doing this Precipitation of the ribosomes with 0 3 *M* magnesium chloride (R Bock, personal communication) resulted in some purification, but the cytidylic and uridylic acids were frequently contaminated The method recently described by Cox and Arnstein[11], in which ribosomal RNA is precipitated free of protein by guanidine chloride solutions, was satisfactory Usually $\frac{1}{2}$ vol of ethanol, in addition to the guanidine chloride, was required to effect the precipitation The small precipitate sometimes obtained without ethanol contained a higher proportion of the pulse-labelled RNA. Usually, however, total ribosomal RNA was prepared. After hydrolysis with 0 3 *N* potassium hydroxide at 37° and acidification, the nucleotides were separated by electrophoresis on cellulose acetate membrane in a citrate–phosphate buffer at *p*H 3 15 The nucleotide bands and adjacent blanks were cut from the paper and their phosphorus-32 contents determined by scintillation counting with the papers in contact with a plastic phosphor Ultra-violet absorption was determined after elution in 0 1 *N* hydrochloric acid Published molar extinction coefficients were applied[12] Ribosomal RNA obtained after a short pulse and a long chase incubation was uniformly labelled, since the specific activities of the four nucleotides were closely similar After a 15-min pulse only, however, the guanylic and cytidylic acids had a much lower specific activity than adenylic and uridylic The composition of pulse and chase labelled RNA is shown in Table 1, and compared with published figures for total DNA and RNA[13] There is no doubt that the composition of the pulse-labelled RNA corresponds closely to that of DNA

Table 1

	Adenylic	Uridylic (Thymidylic)	Cytidylic	Guanylic
Pulse RNA	10	8 4	6 8	6 6
DNA (Heyes[13])	10	8 9	6 2	6 5
Chase RNA	10	8 1	7 3	10 3
RNA (Heyes[13])	10	9 3	8 9	11 7

RNA was prepared from ribosomes and the radioactivity of the mixed 2′ and 3′ nucleotides determined as described in the text Pulse RNA was prepared from a 15 min incubation of the seedlings in phosphorus-32, and chase RNA after a further 80–90 min in phosphorus-31 Average of 4 and 3 determinations respectively

These results provide good evidence that informational or messenger RNA, synthesized on the DNA model and rapidly destroyed, occurs in pea seedlings Spiegelman pointed out, however, that a more complete proof of the identity of informational RNA involves an RNA–DNA hybridization experiment[3] Unfortunately this cannot be obtained at present in the higher organisms, since even DNA alone cannot be re-natured by slow cooling It may be possible, however, to isolate a naturally occurring hybrid, and Bonner and his co-workers already have evidence that this exists[14]

If this messenger RNA is similar to that in bacteria, it is also likely that its production is controlled by the inducer and represser mechanisms described by Jacob and Monod This system could then provide a mechanism for the control of cell development With this in mind, the relationship between the pulse RNA and the state of development of the pea seedling root tip cells is now being investigated

STATUS OF THE EAST AFRICAN SALT-WATER-BREEDING VARIANT OF *ANOPHELES GAMBIAE* GILES

By H E PATERSON

Poliomyelitis Research Foundation, South African Institute for Medical Research, Johannesburg

SEVERAL reports[1–3] have been published of the breeding of *Anopheles gambiae* Giles s l (Diptera, Culicidae) in East African estuarine waters at salinities greater than the normal tolerance limits of the species[4] Records apparently referring to this salt-water-breeding variant range from Zululand[5] to Somalia[6] On Mauritius a similar or identical form occurs[3,7] It has been demonstrated[2,3,5] that this east coast form is not identical with *Anopheles melas* Theobald, which occupies a similar niche on the west coast There are apparently no clear-cut morphological characters which separate the form unambiguously from the typical fresh-water-breeding *A gambiae*[3,5]

The object of this article is to present the results of some preliminary crossing experiments between members of a colony of salt-water-breeding *A. gambiae* from Tanga, Tanganyika (*T*), which was established by Dr. F. Kuhlow, and members of two colonies of typical, fresh-water-breeding *A. gambiae* from Kisumu, Kenya (*K*) and Muheza, Tanganyika (*M*). The following crosses and their reciprocals were set up: *K*♂♂ × *T*♀♀, *M*♂♂ × *T*♀♀. Ultimately, the method used for feeding the larvæ was that described by Shute[8].

F_1 generations were obtained for all the crosses. Table 1 presents the rearing success in each case.

Table 1. Rearing Success in Crosses

Cross (F_1)	No. of eggs laid	Percentage hatch	Percentage first stage larvæ reaching maturity
TK	4,276	30·7	8·7
KT	2,486	40·7	14·7
TM	1,056	21·9	14·8
MT	541	42·9	22·8

TK = Tanga ♂♂ × Kisumu ♀♀, *KT* = Kisumu ♂♂ × Tanga ♀♀, *TM* = Tanga ♂♂ × Muheza ♀♀, *MT* = Muheza ♂♂ × Tanga ♀♀.

Evidence of genetic discordance between the two forms is as follows: (1) Although the feeding regimen used yields healthy adults when applied to the pure parental forms, the adults obtained from the crosses were, in most cases, feeble, many being incapable of flight, despite the fact that the pupæ were large and active. (2) The sex-ratios of the F_1 generations deviated from the expected 1 : 1 as shown in Table 2. It will be noted that although the cross *M*♂♂ × *T*♀♀ yielded a ratio which is not significantly different from the expected, the deviation is in the same direction as that obtained for the corresponding cross, *K*♂♂ × *T*♀♀. (3) F_1 males from crosses which produced a deficiency of males (*T*♂♂ × *M*♀♀ + *T*♂♂ × *K*♀♀) were found to have highly degenerate testes, which were scarcely thicker than the vasa deferentia, and were quite clearly incapable of producing sperms. The F_1 males from the reciprocal crosses had testes of normal size, and spermatogenesis was noted to occur in them. No evidence is available on whether the F_1 females and the F_1 males with apparently normal testes are fertile or not. Because of the weakness of most of the F_1 imagines, only 8 females from the cross *T*♂♂ × *K*♀♀ were available for a backcross to *K*♂♂. Three of these females died within the first nine days and a single female which appeared gravid was then killed and dissected. It was found to have been fertilized and that its ovaries held eggs which were at late Stage 4 or early Stage 5 (ref. 9). The remaining females, although apparently gravid, produced no eggs in the next seven days, when the attempt ended with their accidental death while *en route* to Johannesburg. The ovaries of newly hatched hybrids appeared small but otherwise seemed normal.

Table 2. Sex-ratios in Hybrid F_1 Generations

Cross (F_1)	Males	Females	$\chi^2_{(1)}$	P
TK	26	82	29·04	$< 0·001$
KT	103	14	67·70	$< 0·001$
TM	8	23	7·29	$< 0·010$
MT	31	22	1·53	$0·25 > P > 0·20$*

* Not significant.

Although little time was devoted to looking for morphological differences between the two forms of *A. gambiae*, the eggs were examined for characters. Table 3 presents data on the length of the eggs of the three colonies as well as of P_1 females of the crosses *K*♂♂ × *T*♀♀ and *T*♂♂ × *K*♀♀. The mean egg-lengths of the *K*, *M* and *T* samples are all significantly different from each other ($P < 0·01$), and the means of the F_1 egg samples of the crosses *K*♂♂ × *T*♀♀ and *T*♂♂ × *K*♀♀ are significantly different from the means of the *K* and *T* samples ($P < 0·05$). This is somewhat surprising as egg characters are generally believed to be characters of the mother. It is possible that the results are due to sampling errors, despite efforts to minimize these.

Table 3. Egg-lengths

	n	x (mm.)	S	$S\bar{x}$	C (per cent)	Range
K	100	0·481	0·0196	0·00196	4·1	0·429–0·525
T	100	0·575	0·0172	0·00172	3·0	0·525–0·627
M	100	0·490	0·0252	0·00252	5·1	0·397–0·531
*KT**	100	0·545	0·0234	0·00234	4·3	0·435–0·589
*TK**	50	0·488	0·0179	0·00253	3·7	0·454–0·531

* Eggs of the P_1♀♀.

Of interest, too, is the fact that means of the Muheza and Kisumu colonies should differ significantly. It may be the case that the eggs of the Kisumu colony are smaller than those of most wild populations as a result of some selective influence acting during the years since it was colonized.

Preliminary work indicates that the F_1 hybrid offspring of crosses between the Tanga and the Kisumu and Muheza colonies were intermediate in their tolerance to high salinities.

It is apparent from the crossing experiments that genetic differences exist between the salt-water-breeding variant and typical *A. gambiae* and that at least some of their F_1 hybrids are sterile, and that the others have often impaired viability when compared with the parental forms. These points, taken together with the facts that the two forms are often sympatric in Nature and that these sympatric associations are stable (as at Dar-es-Salaam[1,2]), suggest very strongly that we are dealing with two distinct biological species[10,11]. The alternative possibilities that we are dealing with two sub-species or two polymorphs of a single species, seem unlikely for these reasons: (*a*) If they were sub-species it would be necessary to demonstrate some extrinsic barrier which prevents or strongly limits gene flow between the two populations. Such a barrier does not seem to exist[2]. (*b*) If they were simply 'polymorphs' maintained, perhaps, by disruptive selection[12], one would not find the, at least partial, sterility among the F_1 offspring, nor their relative inviability.

With regard to the naming of the species, only one point needs to be made here; the name *litoralis* given by Halcrow to the salt-water-breeding variant of *A. gambiae* found on Mauritius is not available as it is preoccupied by *A. litoralis* King (1932).

The work described here was performed during the tenure of a World Health Organization short-term consultantship at the East African Institute of Malaria and Vector-borne Diseases, Amani, Tanganyika. I thank the director, Dr. G. Pringle, and his staff for assistance.

STIMULATIVE EFFECTS OF ALUMINIUM ON PLANT GROWTH

By C HACKETT

Imperial College of Science and Technology, Field Station, Sunninghill, Ascot

DURING the course of an investigation of the nutrition of a calcifuge, *Deschampsia flexuosa* (L) Trin , experiments were carried out with different levels of aluminium in water-culture solutions The results strongly suggest that aluminium can be of benefit to plant growth The treatments were applied to seeds (Stage 1), to 4–10 day old seedlings (Stage 2), and to established plants 10–12 weeks old (Stage 3)

The basal nutrient had the general composition given in Table 1, but there were some modifications between experiments The *p*H was maintained at 3 5–3 6, which prevented precipitation of aluminium and phosphate The concentration of sulphur present in the solutions is given in Table 2, amounts added as sulphuric acid in *p*H adjustments are included

Table 1 COMPOSITION OF THE BASAL NUTRIENT SOLUTION

Source	Ca	Fe	K	p p m. Mg	Mn	N	P	S
$CaSO_4$ $2H_2O$	10							7 8
KNO_3			11			3 6		
$MgSO_4$ $7H_2O$				3				4 8
$MnSO_4$ $4H_2O$					1			0 6
KH_2PO_4			2				2	
Fe citrate or Fe-EDTA		0 5						
$Al_2(SO_4)_3$ $16H_2O$								

Trace additions (p p m) Cu 0 01 ($CuSO_4$ $5H_2O$) B 0 14 (HBO_3), Zn 0 04 ($ZnSO_4$ $7H_2O$), and Mo 0 005 ($(NH_4)_6Mo_7O_{21}$ $4H_2O$)

Table 2 CONCENTRATION OF SULPHUR AT DIFFERENT ALUMINIUM-LEVELS

p p m Al added	0	2	5	10	25
p p m S present	20	24	29	38	64

The methods, treatments and results can be summarized as follows

Stage 1 Experimental layout 0, 5 and 25 p p m aluminium × 9 replicate trays × 4 spp /tray

The species used for comparison with *Deschampsia* were *Alopecurus pratensis*, *Festuca pratensis* and *Lolium perenne* The seeds were supported on thin, rigid glass-fibre matting over holes in waxed cork sheet, which was then floated on the surface of 1,500 ml of solution in painted baking trays so that the seeds were in direct contact with the free solution The glass-fibre matting had been soaked for three days in portions of the treatment solutions High relative humidity was maintained by covering the trays with polythene sheet and panes of glass The experiment was carried out under laboratory conditions, with temperatures fluctuating between 13 and 23° C *Deschampsia* was weighed after 11 days and the other species after 7 days, the nutrient was replaced on the fifth day Differences in rates of germination did not contribute to the results showing stimulation by aluminium

The stimulative effect of aluminium appeared in the roots It was highly significant for the overall treatment means (Table 3), but there was some difference in response between the species (Table 4)

Stage 2 Experimental layout 0, 2 and 10 p p m aluminium × 0 1, 1 and 8 p p m phosphorus × 5 spp /jar × 2 replicate jars × 3 replicate groups of seedlings per jar *Agrostis tenuis* was added to the species already named

Table 3 EFFECT OF ALUMINIUM ON IMMEDIATE POST-GERMINATION GROWTH

	Root		Shoot	
	Trans-formed means ($\sqrt{100x}$)	Original data mg/plant fresh wt	Trans-formed means ($\sqrt{x}$)	Original data mg/plant fresh wt
p p m Al added				
0	2 18	(0 09)	1 78	(3 4)
5	3 82	(0 17)	1 73	(3 3)
25	1 75	(0 06)	1 53	(2 5)
S D at 0 05 =	0 80			
at 0 01 =	1 08		at 0 01 = 0 11	

Table 4 EFFECT OF ALUMINIUM ON IMMEDIATE POST-GERMINATION ROOT GROWTH

(In brackets—original data—mg/plant—fresh wt)

p p m Al added	*Alopecurus*	*Deschampsia*	*Festuca*	*Lolium*
0	1 3 (0 5)	2 5 (0 7)	1 2 (0 6)	3 8 (1 5)
5	3 3 (1 3)	3 3 (1 1)	3 1 (1 2)	5 5 (3 1)
25	0 8 (0 3)	3 6 (1 4)	0 0 (0 0)	2 6 (0 9)
		S D at 0 01 = 2 0		

The seedlings were supported in groups of 2 or 3 in holes in waxed cork This framework was floated on nutrient solution held in wrapped 350-ml jars The seedlings were grown for 3 weeks under greenhouse conditions, with three changes of solution per week

Again the stimulation appeared only in root growth The mean fresh weight per seedling group is given in Table 5, with shoot weights for comparison There were no aluminium × phosphorus or Spp × aluminium interactions

Table 5 EFFECT OF ALUMINIUM ON THE GROWTH OF 4–10 DAY OLD SEEDLINGS

	Root	(Means per seedling group)	Shoot	
p p m Al added	Transformed means (log x)	Original data mg fresh wt	Transformed means (log x)	Original data mg fresh wt
0	0 93	(11 1)	1 41	(32 3)
2	1 16	(18 9)	1 26	(26 2)
10	0 98	(12 0)	1 17	(18 9)
S D at 0 01 =	0 16		= 0 19	

Stage 3 Experimental layout 0, 2, 5, 10 and 25 p p m aluminium × 3 replicate jars × 3 groups of plants per jar, using *Deschampsia* only

The plants were held in waxed corks in waxed wooden squares which rested on the neck of 2,700-ml wrapped jars The plants were grown for 6 weeks under greenhouse conditions, with the solutions changed every week

Similar trends to those at Stages 1 and 2 were found, but the stimulative effects were not significant The shoots were affected more than the roots

Table 6 EFFECT OF ALUMINIUM ON THE GROWTH OF ESTABLISHED PLANTS OF *Deschampsia*

p p m Al added	Root (mg dry wt /plant group)	Shoot
0	48	177
2	50	208
5	52	181
10	33	148
25	39	168

(Since these experiments, similar effects have been obtained with young plants of oats and rye, barley did not respond)

In a brief review of the elements considered essential in plant nutrition, Hewitt[1] tentatively described aluminium as a potential micronutrient He referred to the number of reports between 1920 and 1945 of beneficial effects of aluminium on plant growth but noted that the reliability of the conclusions had afterwards been questioned by Hutchinson[2] in a detailed review of aluminium and plant growth Since these reviews, work with aluminium has been concentrated on those levels causing toxicity, and it seems possible that some important effects of lower concentrations have been overlooked, effects which could be of physiological and ecological importance

This work was carried out under the general supervision of Dr A J Rutter and with the financial support of the Department of Scientific and Industrial Research

SOIL DEVELOPMENT AND THE AVAILABILITY OF PHOSPHORUS AND POTASSIUM TO *ASPERGILLUS NIGER*

By Dr B. N ROY

School of Agriculture, Kwame Nkrumah University of Science and Technology, Ghana

THE extent to which the active or kinetic release of minerals to micro-organisms from the various stages of weathering of the soil parent material is not well understood It appears that there is practically no published literature in this respect In the investigation reported here the release of phosphorus and potassium from fresh rock, weathered rock, detritus, lithosol and soil of a basic metamorphic rock (hornblende schist) was studied using the *Aspergillus niger* method[1,2] This method provides a sensitive measure of the amount of phosphorus and potassium available to the organism and should throw a light on the release of these two minerals as the decomposition of the rock advances

The samples representing the sequence of weathering from fresh rock to the soil were collected from the same site, at Creag Liath, Ballater, Scotland, ensuring that all had been subjected to the same soil-forming factors The size fraction (< 2 0 mm) of fresh rock, weathered rock and detritus was prepared by hand grinding in a mortar until all particles passed through a 2-mm sieve This fraction contains a complete size-range of mineral matter similar to soil, namely, coarse sand, fine sand, silt and clay Lithosol and soil were passed through a 2-mm sieve

Table 1 TOTAL PHOSPHORUS AND POTASSIUM CONTENT OF ROCK IN DIFFERENT STAGES OF WEATHERING WITH THE CALCULATED PROPORTIONAL LOSS OF CONSTITUENTS

Constituents	I Fresh rock (per cent)	II Weathered rock (per cent)	III Detritus (per cent)	IV Percentage of each constituent lost*	
				Weathered rock	Detritus
P_1O_5	0 50	0 20	0 10	83 80	93 00
K_1O	2 30	1 60	1 20	64 30	82 70

* Fe_2O_3 used as a constant factor for calculation Calculations for the proportional loss of constituents were carried out according to Merrill[3]

Table 2 PAD WEIGHTS AND THE PHOSPHORUS AND POTASSIUM CONTENT OF THE MYCELIUM OF *A niger* GROWN ON ROCK IN DIFFERENT STAGES OF WEATHERING AND ON SOIL

Sample	Total weights of mycelium from 4 cultures (mgm)		Amount of P_2O_5 and K_2O in 4 pads by analysis* (mgm)		P_2O_5 and K_2O absorbed by *A niger* from 100 gm of sample (mgm)	
	P_4O_5	K_2O	P_2O_5	K_2O	P_2O_5	K_2O
Fresh rock	1,231	814	1 16	0 924	5 80	9 24
Weathered rock	1,067	1,140	1 04	1 202	5 20	12 02
Detritus	1,344	1,148	1 24	1 562	6 20	15 62
Lithosol	1,958	1,841	2 06	2 035	10 30	20 35
Soil	2,278	2,466	2 29	2 634	11 45	26 34

* Total phosphorus and potassium in the mycelial pads were determined according to Mehlich *et al* [6]

Phosphorus and potassium both exhibit a correlation between the amounts of these minerals released and the stage of weathering It will be seen that in spite of a great loss of phosphorus and potassium in the course of weathering, as revealed by rock analysis (Table 1), the release of these two minerals to *A niger* is found to increase with the advancement of decomposition The pad weight in relation to phosphorus (Table 2) diminishes slightly from fresh rock to weathered rock, but again the weight increases significantly on passing from detritus on to the soil The significant release of phosphorus from detritus to soil is of interest in view of the findings of Polynov[4] and Nikiforoff[5], who have concluded that apart from physical and chemical weathering which render minerals available, the effect of pioneer organisms—especially lichens and mosses—in organic weathering cannot be overlooked The presence of these organisms in detritus, lithosol and soil is frequent The increase in pad weight, in relation to potassium (Table 2), is significant throughout The total phosphorus and potassium in the mycelial pads (Table 2) grown on samples in general, parallels the weights of all the pads The release of these two minerals increases in a manner corresponding with the increase of pad weights These determinations, however, tend to emphasize that the amounts of phosphorus released to micro-organisms increases sharply in the later stages of weathering, but for potassium there is a definite gradual trend to release more as the decomposition of the rock advances

This work was carried out at the Department of Soil Science, University of Aberdeen I thank Dr W T H Williamson for his advice

METABOLISM OF PHENOLIC COMPOUNDS BY YEASTS

By G. HARRIS and R W RICKETTS

Brewing Industry Research Foundation, Nutfield, Surrey

THE ability of several species of bacteria to metabolize phenolic compounds supplied as sole carbon source is well known, and it has been recognized that certain fungi, including species of *Aspergillus*, *Penicillium* and *Neurospora*, likewise bring about some of the reactions involved[1] Strains of the yeast-like fungi, such as *Oospora*, also metabolize phenolic substances[2], including those derived from lignin[3], but less is known of the fate of these materials in yeasts themselves That *Saccharomyces cerevisiae* could be trained to tolerate poisons such as phenol or 'sublimate' and that such training resulted in morphological and physiological changes in the cells was established by Imshenetsky and Perova[4] Moreover, Zimmerman[5] has described the destruction of phenol by four yeasts comprising one strain each of *Saccharomyces cerevisiae*, *Candida tropicalis*, *Rhodotorula glutinis*, and an unidentified 'white yeast' In a survey of the properties of moulds and yeasts from soils and allied habitats, di Menna[6] observed that his strain of *Candida tropicalis* failed to attack the lignin derivatives, including ferulic acid, p-hydroxybenzoic acid and vanillin, but others of these yeasts did so This article describes the preliminary findings of a survey of the ability of a wider range of yeasts from the British National Collection of Yeast Cultures to grow on various phenolic substances (cf Tables 1 and 2)

The initial investigations were made using catechol as, first, this compound is a common intermediate in the bacterial dissimilation of phenols[1] and, secondly, of a number of phenols tested in preliminary trials it supported the most rapid growth of yeasts The medium consisted of a mixture of catechol solution (200 ml , 0 1 per cent) and Wickerham's 'carbon assimilation' medium[7] (20 ml) at ten times its normal concentration Portions (10 ml) were inoculated heavily with the selected yeasts, which had been grown up on malt extract–yeast extract–glucose–peptone medium (MYGP), and the cultures were shaken aerobically at 25° C The amounts of growth, estimated after 3, 7 and 14 days, are given in Table 1 Clearly, ability to grow on catechol under these conditions is limited to relatively few genera, mainly *Candida*, *Debaryomyces*, *Pichia*, *Saccharomyces* and *Torulopsis* and usually to only a few species However, of the seven strains of *Debaryomyces* tested, three actively metabolized catechol in contrast to the strains examined by di Menna[6], and all the strains of *Torulopsis* used grew on the same substance With the latter genus, however, growth was only weak, except in the case of *Torulopsis famata*, which grew as well on catechol as on MYGP The most active yeasts were strains No 405 and 470 of *Candida tropicalis* and strain No 459 of *Debaryomyces subglosus*, which grew strongly within three days Even using these yeasts, however, growth was inhibited when the concentration of catechol was increased above 0 1 per cent and inhibition of the growth of *Debaryomyces subglosus* (459) was complete when this concentration was 0 5 per cent

The substitution of other phenolic compounds (Table 2) for catechol permitted growth in certain instances Generally speaking, the faculty of growing on catechol was paralleled by ability to metabolize

both phenol and resorcinol In the case of *Debaryomyces subglosus* (459) it was accompanied by the capacity to utilize *p*-hydroxybenzoic acid and protocatechuic acid However, *Saccharomyces pastori* (175) although able to metabolize catechol slowly, failed to grow on either phenol or resorcinol

The routes by which phenolic compounds are metabolized by bacteria are rapidly becoming clear As indicated here, phenol, for example, is degraded via catechol and then either *o*-quinone, *cis-cis*-muconic acid and β-oxoadipic acid or 2-hydroxymuconic acid and its transformation products, the simple acids finally formed entering the terminal respiratory systems In the present investigation the formation of a quinone from phenol in the presence of *Candida tropicalis* spp was observed but addition of aniline to the media during dissimilation of the other substrates by the yeasts (Table 2) failed to yield quinone anil except from protocatechuic acid The anil was isolated as described by Evans[8] as follows a washed culture of *Debaryomyces subglosus* (459) from MYGP (20 ml) was inoculated into Wickerham's medium[5] (2 l) containing aniline and potassium protocatechuate each at 0 1 per cent concentration and the whole shaken aerobically at 25° C After seven days the mixture of yeast and thick red precipitate was removed, extracted by means of boiling ether and the ethereal extract dried and evaporated Dianilino-*o*-benzoquinone (100 mgm), m p 190°, separated on crystallization of the product from light petroleum (b p 100°–120°) and failed to depress the m p (191°) of authentic material[9]

It is of interest that the oxidation of protocatechuic acid by the bacterium, *Pseudomonas fluorescens*, for example, in presence of aniline fails to yield an anil because cleavage of the aromatic ring of the acid occurs without decarboxylation[10–13], a change occurring also in *Neurospora* spp [14] Possibly, therefore, the production of quinone from protocatechuic acid described here depends on prior decarboxylation of an unstable acidic intermediate The metabolism of protocatechuic acid but not *p*-hydroxybenzoic acid by *Debaryomyces hansenii*[9], in contrast to *Debaryomyces subglosus*, which utilizes both acids, may reflect the failure by the former yeast to adapt to the mono-hydroxy compound under the conditions used, as in bacteria this acid is converted into protocatechuic acid[8,15] Both these findings, together with the inability to detect dianilino-*o*-quinone during the metabolism of the above phenols other than protocatechuic acid, suggest that adaptation experiments as introduced into this field by Stanier[16] may help to decide which oxidative pathways for phenols exist in yeasts

MODIFICATIONS OF GREEN ALGAE TO BE USED AS FOOD

By D STRIETELMEIER* and ROBERT B KOCH†

Chemistry and Microbiology Branch, Food Division, Quartermaster Food and Container Institute for the Armed Forces, QM Research and Engineering Command, U S Army, Chicago 9

THE most undesirable characteristics of the green alga *Chlorella* as a food are the deep green colour, a bitter taste, and a tough cell wall which inhibits the efficient absorption of nutrients from the cell by non-ruminant animals[1] Green algae have been found to be acceptable, however, if added to food in small concentrations Thus, when less than 10 per cent is incorporated in Japanese and Western style soups, bread, noodles, cakes and ice cream, no significant effect on acceptability is observed As much as 20 per cent has been added to Japanese green tea with equally good results[2]

This article represents one phase in an attempt to develop a high protein product for use as a food extender from a strain of *Chlorella* (Sorokin) with a high-temperature optimum for growth In this work it was postulated that an extraction procedure could be developed which would modify the colour and remove the bitter principle of *Chlorella* Thus, high concentrations of extracted algae could be added to low-protein foods without a significant reduction in the acceptability of the food

Evidence in the literature suggests that methanol extraction would minimize the colour and bitter principle problems[3,4] The literature does not indicate, however, the colour of the extracted algae in precise, mathematical terms The 1931 C I E colour values have been used in the present work to represent the colour of the algae When these values are plotted on the C I E -Munsell system conversion tables, the Munsell notation indicates the colour of the algae as it appears to the human eye

Extraction by methanol has an additional advantage in that recent work using the albino rat has shown that the extraction increased nutrient absorption from 54 5 to 81 7 per cent[4] The extraction also increased the digestibility of protein from 46 2 to 65 5 per cent

Conditions of growth influence the composition of algae[5] Variations in chlorophyll content and cell wall composition could result in corresponding variations in the time required for extraction and the completeness of extraction For this reason, an effort was made to maintain constant conditions for growth and collection

To maintain careful control of the culturing process, the algae were grown in batch culture in Burk's[6] nutrient medium, except for the substitution of urea as a nitrogen source The algae were grown in a 100-l tank and illuminated with fluorescent light The suspension, 0 1–0 8 gm of algae/l, was circulated by pump to create sufficient turbulence for maintaining a uniform suspension and to effect maximum solubilization of carbon dioxide The air supply was enriched with carbon dioxide to a 5 per cent level using a dry-ice converter Collection was accomplished by centrifugation at 25,000 r p m, with a Sharpless-Super centrifuge, resulting in a paste of 30 per cent dry solids Usually, 200–230 gm of algae paste was gathered every two days The supernatant was re-cycled, and fresh nutrients were added to replace that depleted by the algae The quantity of fresh nutrients required depended on the amount of algae gathered

After a wash to remove residual nutrients, a quantity of paste equivalent to 39–40 gm dry solids was blended in a Waring blender in 200 ml of methanol for 30 sec The heat evolved by blending in excess of 1 min appeared to fix pigment and produce a brownish discoloration that could not be extracted by methanol The methanol suspension of algae was poured into a single-strength cellulose extraction thimble of the dimensions 60 mm × 180 mm The thimble was transferred to a Soxhlet, and the latter was fitted to a 3-l boiling flask containing 1 l of methanol The methanol was distilled at the rate of 2 5 l/hr The Soxhlet cycle-time averaged 3 min with the withdrawal of 125 ml of extract at the end of the cycle

The problem of solvent channelling was solved by continuous stirring of the methanol suspension during the extraction period A glass stirring rod with attached propeller was extended through the Soxhlet condenser into the extraction thimble The stirring was accomplished at 200–400 r p m, with the result that the algae were kept in suspension except for a layer of solids on the sides of the thimble It was observed that rate of stirring influenced the rate of extraction When stirring at 100 r p m, 5 hr were required for complete extraction, while only 2 5 hr were required at 200 r p m

Following extraction, the suspension was filtered The methanol-extracted algae had a noticeable green colour In an attempt to remove the last traces of green colour, the extracted algae were suspended in a 3 per cent solution of hydrogen peroxide At room temperature, a more complete decolorization was effected in 18 hr The bleaching time was reduced to 5 hr when a 5 per cent solution of hydrogen peroxide was used The white paste, obtained after centrifugation and washing with distilled water, was freeze-dehydrated to remove residual solvents

Light reflectance measurements were made with a 'Color Eye' tristimulus colorimeter using a white vitrolite standard calibrated against magnesium oxide (Table 1) The tristimulus Y values showed that the bleached methanol extracted was lighter in colour than the methanol extracted algae However when the x and y values of the bleached algae were plotted on the C I E -Munsell system conversion tables, the Munsell notation indicated a slight greenish hue

Table 1 EFFECT OF METHANOL EXTRACTION AND HYDROGEN PEROXIDE ON THE COLOUR AND PROTEIN CONTENT OF A TYPICAL SAMPLE OF *Chlorella* C–32

Treatment of algae	Dry weight (gm)	Crude protein ($N \times 6$ 25) dry basis (per cent)	Colour—1931 C I E values of freeze-dehydrated product		
			Y	x	y
(1) Raw	39	48 0	13 61	0 3478	0 1725
(2) Methanol extracted	27	68 2	63 32	0 3159	0 3569
(3) Methanol extracted, 3 per cent H_2O_2	25	69 0	67 20	0 2973	0 3363

Methanol extraction removed about 12 gm of solids or 31 per cent of the total dry weight of the raw algae (Table 1) The methanol-extracted algae was found to have 0 3 per cent ether-soluble fat Approximately 2 gm of dry solids were recovered in the supernatant from the hydrogen peroxide bleach, accounting for the difference in weight between the methanol extracted and bleached algae (Table 1) The bitter principle present in this strain of algae was found to have been completely removed by the methanol

Table 1 shows an increase in the crude protein content from 48 per cent in the raw to 69 per cent in the bleached methanol-extracted algae Comparable decolorization was obtained by 'solarization' (illumination at very high light intensities), by which the algae are forced into a state of rapid respiration accompanied by the cessation of photosynthesis However, the crude protein content was reduced to only 6 per cent Therefore, if it is important to retain high protein content, methanol extraction is preferred to the 'solarization' method of decolorization

Various methods of cell rupture in green algae were also investigated These included sonic oscillation at 10 kc/s, extended treatment in a Waring blender and a Virtis 45 homogenizer, and grinding in a ball mill These methods were all effective, but required treatment for extended periods of time However, it was found that the methanol extraction process was as effective as these supplemental treatments The 2 5 hr treatment, already described, resulted in as many as ten fractures of the cell membrane per cell (observed under 970 magnification) This may account for the earlier report[4] that methanol extraction increases the absorption of cell constituents to an acceptable level

Methanol extraction effectively removed the bitter taste of *Chlorella*, and also fractured the cell membrane, making the constituents more available for assimilation Methanol extraction with supplemental treatment with hydrogen peroxide decolorized *Chlorella*, resulting in a colour described by

Munsell notation as near white with a slight greenish hue. The methanol-extracted algae were found to be 65 per cent crude protein.

THE BIOLOGICAL CLOCK AT THE SOUTH POLE

By Prof. K. C. HAMNER, J. C. FINN, jun.,* G. S. SIROHI, T. HOSHIZAKI†
and B. H. CARPENTER

Department of Botany, University of California, Los Angeles

FOR many years biologists have known that plants and animals possess a mechanism—the biological clock—which permits accurate measurement of time. The twenty-fifth Symposium of Quantitative Biology at Cold Spring Harbor[1] was devoted entirely to the subject of biological clocks. Since, in many cases, periodic oscillations in metabolic or physical activities have been shown to persist even when an organism is placed under conditions of constant temperature and constant light or darkness, they have been regarded as manifestations of endogenous rhythms.

Diurnal endogenous rhythms have been designated 'circadian rhythms' because their periods are not exactly 24 hr. in duration. The use of biological clocks in compensating for the Sun's apparent motion has been well demonstrated[1] in experiments which show that bees, birds and many other animals navigate to a particular goal by utilizing the Sun for orientation. It has also been shown that certain birds navigate apparently by 'sighting' on the stars and using their internal clocks much as a ship's captain uses a chronometer[2,3]. Photoperiodic responses of plants and animals appear to be dependent on biological clocks[1]. Organisms which are situated a sufficient distance from the equator are thus afforded an accurate estimate of the calendar day. Hence, biological clocks serve as a key factor in survival of many species.

One of the basic questions raised by students of biological clocks has been whether organisms growing under supposedly constant conditions actually may be receiving information from their environment. F. A. Brown, jun.[4], has pointed out that there are diurnal fluctuations in the air pressure and slight periodic fluctuations in gravity associated with the rotation of the Earth in relation to the Sun and Moon. Brown claims correlation between certain rhythms which he has been measuring and cosmic-ray intensity. However, no one has definitely shown that the clock mechanism present in many organisms, perhaps in all, is guided by any particular factor of the external environment. Since Brown has been the chief proponent of the hypothesis that external factors, over which the experimenter has no control even under so-called constant conditions, are influencing the clock, it seems worth while to quote briefly from two of his recent reviews.

He states: "The characteristics of the rhythmicity in living things of the kind that have just been described led many investigators of the phenomenon many years ago to the conclusion that living things possess within themselves clock mechanisms that would permit them when isolated from all environmental changes which are conceded to be able to influence them, to measure off accurately periods closely corresponding to the length of the solar day and other natural periods. In other words, there was postulated to be operating in living things a completely independent complex of rhythms which parallel in their natural periods the complex known for the external physical environment. The thesis supported in this article, namely, that during the timing of cycle-length in the rhythm in animals and plants in so-called 'constant conditions' the organisms are still continuously receiving from the external environment information about the natural geophysical cycles"[5]. Brown further states, "However, short of the demonstration that biological cycles of the natural geophysical periods can still persist in organisms travelling in space well outside of the Earth's rhythmic field of influence, there is no logical basis on which this hypothesis can be rejected"[6].

It is obviously difficult at present to examine rhythms in organisms travelling in space away from the influence of the Earth. However, there are two places on the Earth, the geographical poles, where all diurnal variables can be essentially eliminated. Organisms could be placed on turntables which, if revolved counter to the Earth's rotation once each 24 hr., would completely eliminate diurnal rotation. In such circumstances it would be inconceivable that organisms could receive any information of a diurnal nature from the external environment, except that which might be accidentally introduced by the experimenters and that which might be associated with the daily 'rotation' of the magnetic pole about the geographical pole. These latter variations are very slight indeed and will be discussed later.

A project which would enable us to conduct appropriate experiments on the functioning of the biological clock at the South Pole was submitted to the National Science Foundation for inclusion in the 1960–61 U.S. Antarctic Research Program. The project was accepted and funds became available in July 1960. Departure was scheduled for Antarctica in November 1960. Special temperature-controlled shipping containers were constructed for transport of organisms from Los Angeles to the South Pole. Only a very

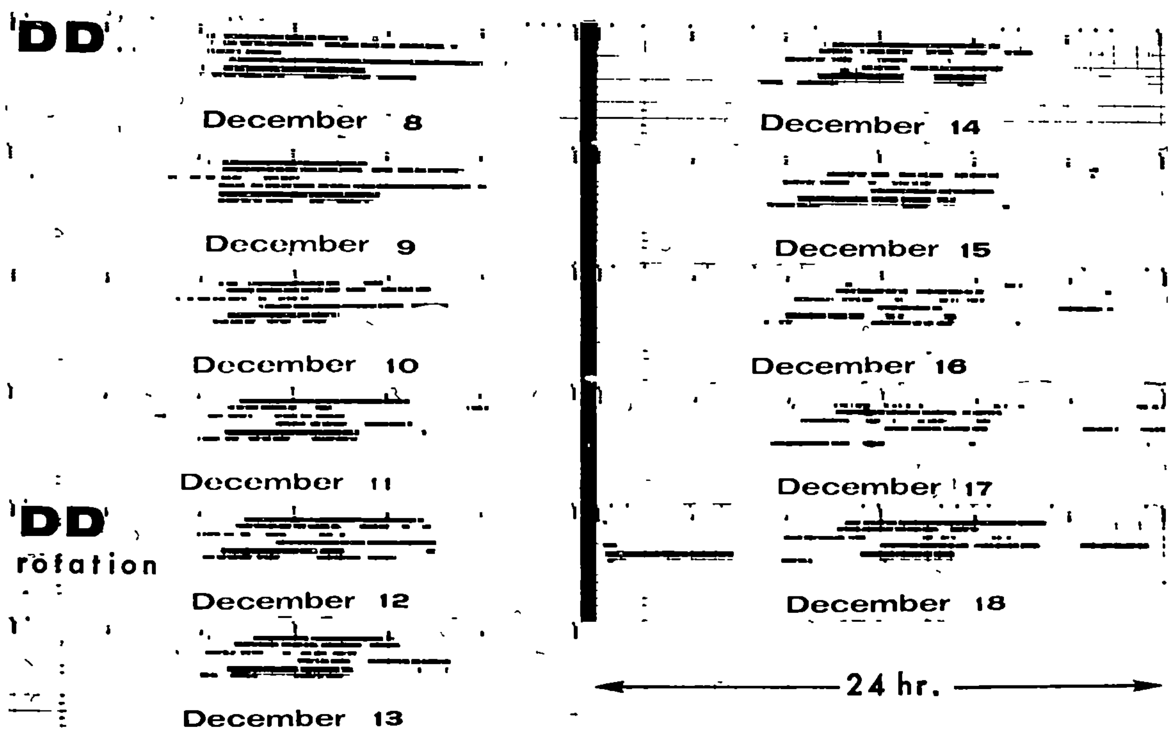

Fig 1 Effect of rotation in constant darkness on the running activity of six different hamsters Prior to December 8, the animals received 12 hr of light during 8 a m –8 p m New Zealand time During the 4 days of the experiment the animals received constant darkness and no rotation The turntables beneath four of the animals were activated on December 12 The activity of the animals is indicated by the vertical pen markings on the chart, which fuse to give a solid band during intensive activity The daily records presented are from noon to noon For example, the December 8 record includes the time-span from noon of December 7 to noon of December 8 All the other calendar days are similarly shown The individual treatments, which were initiated on December 12, are shown in sequence from top to bottom of each daily record Periods of rotation of the animals with respect to the Sun were 24 0, 28 8, 20 0, 24 0, 20 0 and 28 8 hr

limited period of time was available following funding for the design and fabrication of equipment, and the testing of various organisms An arbitrary selection was made of five different manifestations of the biological clock, all of which represent circadian rhythms running activity of the hamster, rhythmic activity of the cockroach, growth rhythms of the fungus *Neurospora*, eclosion of *Drosophila* and leaf movements of bean plants

Hamsters (*Mesocricetus auratus*, Syrian golden hamster) Eight cages with exercise wheels (Geo H Wahmann Manufacturing Co , Baltimore, Md) were each fitted with a plywood box, reinforced with aluminium framework The front of the box consisted of a sliding door which, when closed, made the interior of the box light-tight The plywood box served as a shipping crate and, at the Pole, as an experimental dark room for each cage A box, together with its cage, was mounted on the appropriate turntable for experimentation Each exercise wheel was connected by a reducing gear to a microswitch that sent impulses to a recorder Ten revolutions of the exercise wheel produced a single impulse Each cage was fitted with an automatic watering device and each box was provided with lightproof ventilation Food consisted of apples and a commercial preparation in the form of dried pellets Each of eight aluminium turntables was driven by a synchronous motor through a set of gears which permitted rotation in either direction at speeds equivalent to one revolution in 12 hr , one, two, four, six or eight days

Bean plants (*Phaseolus vulgaris* L , var Scotia) Plastic cups with holes for bottom drainage were used as containers for the vermiculite medium Seeds were planted about 1 in below the surface Cool white fluorescent lamps spaced 2 in. apart and 24 in from the plants provided the only illumination

A record of leaf movements while plants were on the turntables in complete darkness was made in infra-red radiation with a time-lapse camera actuated by a intervalometer Since it was necessary to hold all the plants in the same focal plane, eight turntables were mounted in each of three rows, one row above the other Each turntable was large enough to hold one potted plant Each turntable in a row was attached to one gear train of eight gears so that adjacent turntables rotated in opposite directions Each of the three gear trains was driven by a common shaft The common shaft was driven by a motor through an attached gearbox which permitted all the turntables to be rotated once every 24 hr , and every one, two, four, six or eight days The entire mechanism was housed in an aluminium frame Any of the turntables could be disconnected from the rest of the set to provide stationary controls

Neurospora (*N crassa* 21863), Dr W H Brandt, Oregon State University) Cultures were grown on a thin layer of 'complete' medium in glass tubes about 0 5 in in diameter and about 16 in long, having turned-up ends fitted with cotton stoppers A short layover at McMurdo N A F , the main air base and supply centre for Antarctica, enabled us to provide fresh culture tubes in the laboratory of Dr Wohlschlag In preliminary tests, cultures were exposed to light for about 12 hr after inoculation and then placed in complete darkness Subsequent growth exhibited distinct zonation, one band each 24 hr Zonations were produced by differences in the

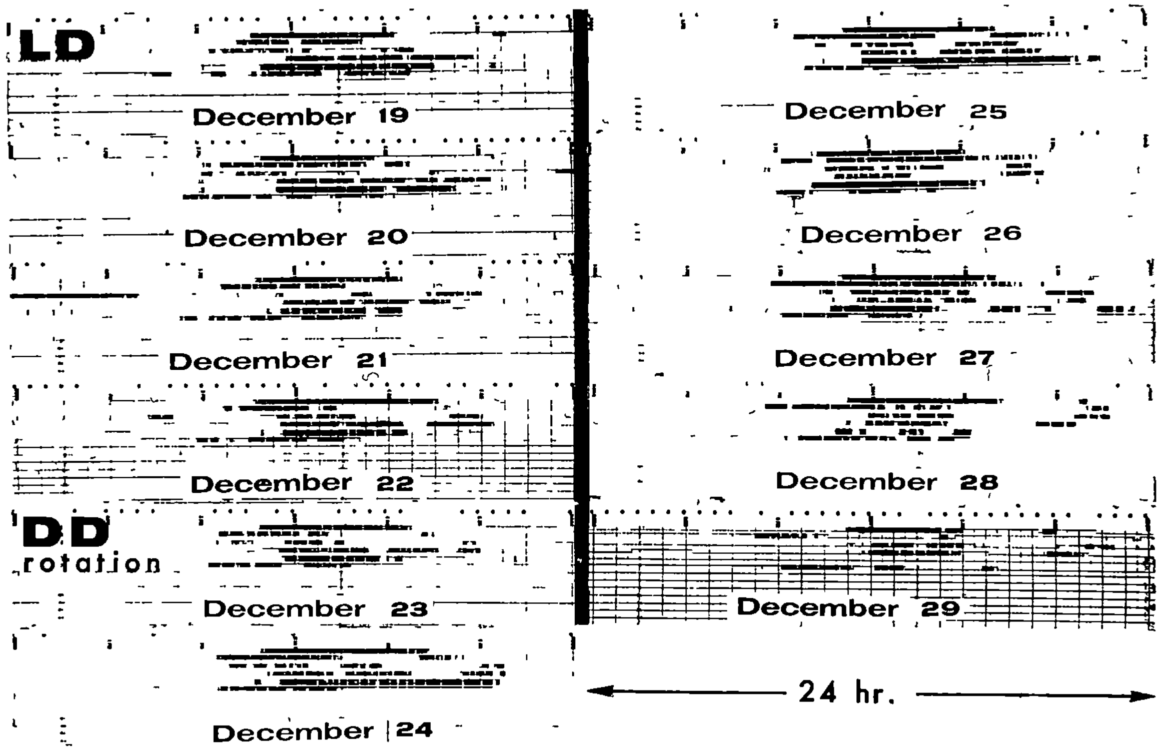

Fig 2 Running activity of six different hamsters The treatments were started on December 23 Prior to that date the animals received light during 8 a m -8 p m The presentation is similar to Fig 1 except the treatment of the animals, which is as follows The six animals, in the order of their activity from top to bottom of the chart, received the following treatments controls 1, 4 and 5 received no rotation, 2, 3 and 6 were rotated once each 24 hr counter to the Earth's rotation

character of growth and colour of the mycelium Hamster turntables were also used for *Neurospora*

Drosophila (*D pseudo-obscura*, Chiricahua-8, Prof Carl C Epling, Department of Botany, University of California, Los Angeles) Cultures were maintained in cotton-stoppered, half-pint milk bottles on a standard media Fresh media were prepared at McMurdo N A F Hamster turntables were also used for this series of experiments

Cockroach (*Periplaneta americana*, Dr I B Tarshis, Department of Entomology, University of California, Los Angeles) Activity was recorded by the same camera system used for recording leaf movement, during quiescent periods the cockroaches were stationary on film and blurred during active periods Cockroaches were maintained in 1-gallon large-mouth glass jars containing hamster food, water and a wire screen for exercise Again, hamster turntables were used

Experiments were conducted in an unused garage about 800 meters from the geographical South Pole Circulation of the air within the building was provided by electric fans Since the floor of the building remained quite cold, all the experimental animals were maintained on tables about 3 ft above the floor Except for one sudden drop in temperature to about 60° F, which was caused by a failure in the heating system, the temperature remained between 68° and 72° F throughout the experimental period

Hamsters The activity of the hamster was adjusted to New Zealand time during a short stay there and during the period of transportation to the Pole by exposing the animals each day to light from 8 a m until 8 p m, New Zealand time One day after arrival at the Pole the animals were placed in experimental cages and recorders were connected Cages were placed in the light-tight boxes and the boxes were mounted one each on a turntable The turntables were not activated in the first four days, during which period the light treatments were continued. The animals began their running activity about 8 p m, were active during the night and inactive during the day On December 8 a large quantity of water and food was placed in each cage, the light-tight boxes were closed The turntables under four of the cages were activated on December 11, while the other two remained inoperative, serving as controls Two cages moved clockwise at the rate of one revolution in six days, the other two moved at the same speed counterclockwise Thus, with respect to the Sun, controls rotated once every 24 hr, two cages rotated once every 20 hr and two cages once every 28 8 hr

A record was made of the activity of the animals for the next eight days Results are shown in Fig 1 During the first five or six days in complete darkness, the animals' activity persisted during that period corresponding to the New Zealand night, whether turntables were rotated or not Toward the end of the experiment, activity of some of the animals became erratic, possibly due to exhaustion of food and water supplies

A second experiment with hamsters was begun immediately on conclusion of the first Some of the animals were replaced, then all were exposed to light from 8 a m until 8 p m, New Zealand time, for four days prior to rotation of the turntables On the fifth day the cages were closed and three of the turntables were activated so that they rotated counter to the Earth's rotation once each 24 hr The other three were inactive and served as controls Results of this second experiment (Fig 2) show that there was no apparent effect of rotation on the rhythmic activity of these animals. As in the previous experiment, the animals' activity became irregular during the last two or three days, although this time food and water were not lacking. The control animals exhibited more erratic activity than the test animals.

Drosophila. Stock cultures were exposed to light each day between 8 a.m. and 8 p.m., New Zealand time, both in New Zealand and also at McMurdo Station. Each experimental bottle was supplied with several mature males and mature females on December 14. The cultures were kept in 12 hr. light from 8 a.m. until 8 p.m., New Zealand time, for 16 days during the period of egg-laying. Cultures were then placed in continuous darkness on December 30. Each of four groups, six bottles per group, were placed in a light-tight box. One group served as a control and remained in a fixed position. Each of the other groups was mounted on a turntable. One turntable was adjusted so as to rotate counter to the Earth's rotation once every 24 hr. Another turntable rotated counter to the Earth's rotation once every six days. A third turntable rotated in the direction of the Earth's rotation once every six days. With respect to the Sun, therefore, the cultures rotated as follows: the control rotated once every 24 hr.; the second group did not rotate; the third experienced one rotation every 28·8 hr.; and the fourth underwent one rotation every 20 hr. Flies began to emerge during the first day of continuous darkness. The flies in individual cultures were removed every 2 hr. in total darkness by shaking the flies down into a receiver flask; flies were then exposed to ether and counted. In every case, cultures were returned precisely to their former position and orientation on the turntable. The results are presented in Fig. 3. Rotation of *Drosophila* on the turntables had no effect on the very well-defined rhythmicity of eclosion.

Neurospora. (Prof. Geo. Meyer, University of Texas, was kind enough to inoculate our experimental culture tubes and also to confirm our observations at the conclusion of the experiments.) After the experimental tubes were inoculated they were exposed to continuous light for 48 hr., during which time the mycelia grew approximately 1 in. in the tubes. A mark was made on each tube indicating the advancing edge of the mycelia. The cultures were divided into four groups of five tubes each. Tubes were wrapped carefully in photographic dark cloth so that the cultures were in complete darkness. One group on a stationary turntable served as the control throughout the experimental period. A second turntable revolved counter to the Earth's rotation once in six days; a third turntable turned counter to the Earth's rotation once in 24 hr.; and a fourth rotated in the direction of the Earth's rotation once every six days.

On inspection of the tubes after seven days, seven distinct zones of growth were noted. There was no difference between the zones of any of the cultures. A photograph of the cultures is shown in Fig. 4. Zonation is not as evident in the photographs as it was to the naked eye because of the film's reduced sensitivity to differences in colour. Rotation of *Neurospora* on turntables did not cause a change in the circadian rhythm of zonation.

Bean plants. Cultures were watered with nutrient solutions prepared from the proprietary mixture 'Spoon-it'. The entire growing area, including the fluorescent lights, was enclosed in a plastic covering in order to increase the normally low relative humidity to approximately 60 per cent at 70° F. The seeds germinated rapidly and plants grew with reasonable vigour. After the plants were about 8 in. high and one tri-foliate leaf was evident, they were placed in a dark room constructed of photographic dark cloth. Relative humidity in the dark room was maintained between 50 and 70 per cent at 70° F. Some of the plants served as stationary controls, while others were rotated either counter to the Earth's rotation or in the direction of the Earth's rotation at various rates. Plants were photographed every 20 sec. in infra-red light for several days until film revealed a reduction in plant vigour. The film clearly shows that the rhythmic leaf movement in all twelve experiments was unaffected despite rotation on the turntables.

An interesting secondary result appeared in these photographs. In the literature there have been

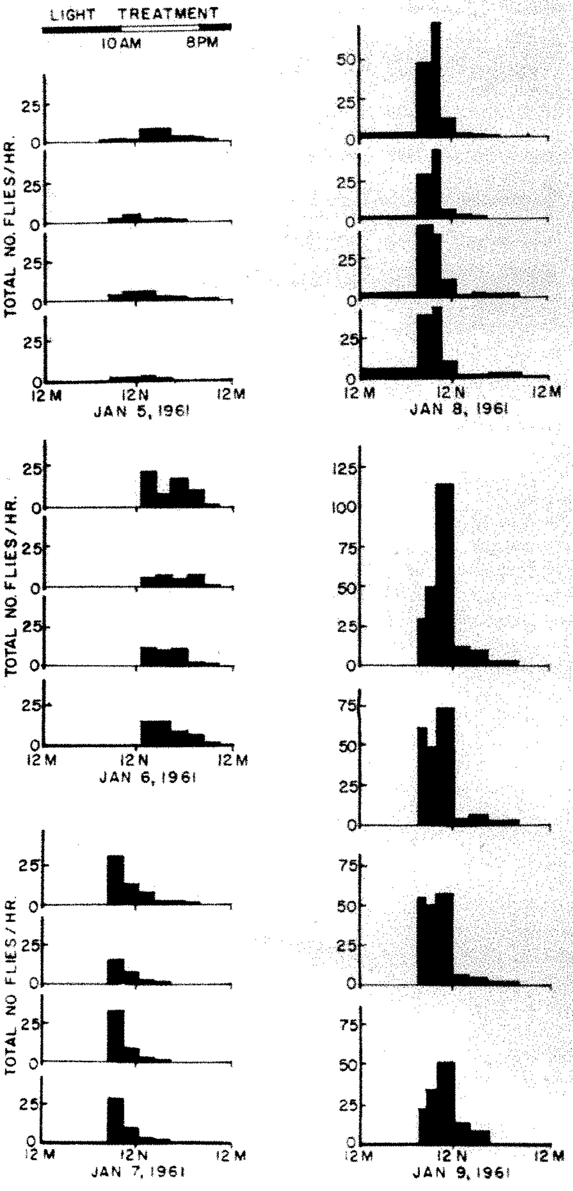

Fig. 3. Effect of rotation on the eclosion rhythms of *Drosophila pseudo-obscura* in constant darkness. The daily record presented is from midnight to midnight. Total number of flies per six cultures of each treatment (ordinate) is shown against time (abscissa) *M*, midnight; *N*, noon

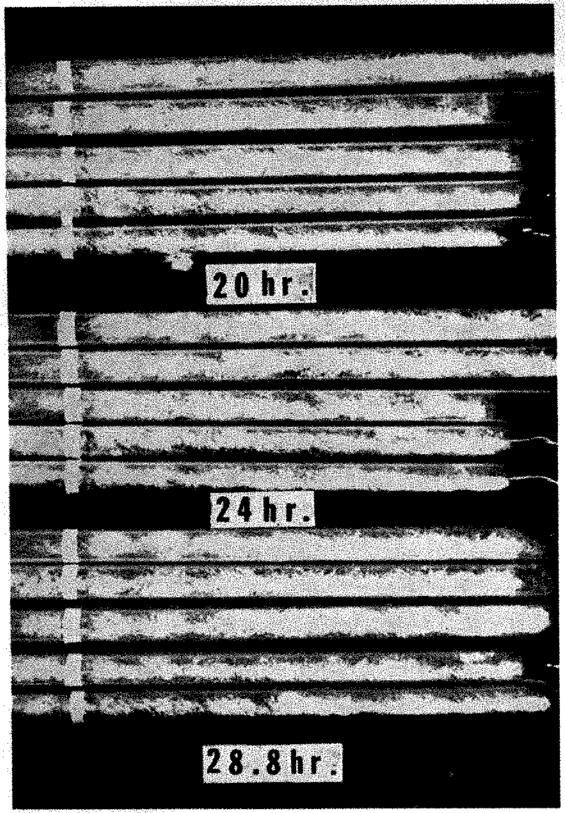

Fig. 4. Effect of rotation on the zonation pattern in the growth of *Neurospora* in constant darkness. The white band on the left-hand side is the marker to denote the extent of growth when the tubes were transferred to total darkness. The tubes were rotated for seven days with respect to the Sun as follows. Top to bottom: (1) Five tubes, once each 20 hr.; (2) five tubes, once each 24 hr.; (3) five tubes, once each 28·8 hr.

claims that the twining of plants in the southern hemisphere is counter to that in the northern hemisphere. All the plants in this experiment exhibited very vigorous counter-clockwise twining, regardless of the direction of turntable rotation or rates of rotation. In one experiment the plants were rotated counter to the Earth's rotation once each 12 hr., which means that with respect to the Sun they were rotated in the opposite direction to the Earth once every 24 hr. In spite of this, twining continued in the same direction and at the same rate as in the control plants.

Cockroaches. Neither the controls nor the cultures on the turntables gave any evidence of rhythmicity in activity. On return to Los Angeles the same strain of cockroaches were found to exhibit no evidence of rhythmic activity. Therefore, the negative results obtained at the Pole station were due entirely to the unfortunate selection of this cockroach strain and hence had nothing to do with the polar location of the experiments.

Prior to the experimental programme at Antarctica, one of three results was anticipated; (1) all external expressions of rhythmicity would cease because the experiments were carried out at the Pole; (2) the rhythms would be altered to new frequencies on the turntables; (3) the diurnal rhythms of none of the organisms would be influenced by either location at the Pole or by rotation on turntables at the Pole. Our data conclusively support the last possibility.

From these results it can be stated that external environmental variables of a diurnal nature associated with the rotation of the Earth have no detectable influence on the basic mechanism, the *Zeitgeber*, of the biological clock. During the period of experimentation there was essentially no diurnal variation in human activity within the building since the continuous light of the summer period permits uninterrupted surface activity at the Pole. It is true that there are slight variations of a diurnal nature in the magnetic field at the South Pole. These are associated with the 'rotation' of the magnetic pole around the geographic pole. On return to Los Angeles several experiments involving *Drosophila*, *Neurospora* and bean plants were conducted to determine the effect of magnetic fields on rhythms. A permanent magnet was placed to one side of a large turntable. As the turntable rotated at speeds comparable with those used at the South Pole, organisms mounted near the periphery were exposed alternately to high (25 gauss) and low (0·68 gauss) intensity magnetic fields. At no time were the circadian rhythms disturbed by changes in the magnetic flux.

It might be argued that with organisms such as the hamster and *Drosophila* the pre-conditioning of the organisms in New Zealand and at the McMurdo Station might have produced a carry-over effect during the experiment at the Pole. However, it is difficult to see how such an argument would hold for movements of plant leaves and for zonation in *Neurospora*. The bean plants were grown from seed at the Pole station, and at no time were the seedlings exposed to diurnal fluctuations in temperature or light. While the *Neurospora* were exposed to diurnal variations during transportation to the Pole, only a small amount of inocculum was used in preparing the experimental culture. Thus, it would seem likely that in the period of growth in the experiment any effect of the previous treatment would have disappeared.

We conclude, therefore, that although it is possible that some external periodic stimulus may regulate the biological clock, it does not arise from any factor associated with the Earth's rotation. We feel that these results give a negative answer to one particular hypothesis concerning regulation of the biological clock by geophysical stimuli. We appreciate the fact that these experiments have not added any information concerning the real nature of the clock other than to make highly improbable this one particular hypothesis concerning regulation of the clock's mechanism.

We thank the U.S. Military Air Transport Service for carrying more than one ton of equipment with dispatch, and without damage, from San Francisco to New Zealand. Likewise, we thank the U.S. Antarctica Research Project in getting our equipment from New Zealand to the South Pole without mishap. The co-operation of U.S. Navy and U.S. Air Force personnel is greatly appreciated. We especially thank Messrs. Edward E. Goodale, George R. Toney, Drs. George H. Meyer and Donald E. Wohlschlag and Lieut. Philip K. Schwartz, U.S.N., without whose support the execution of this work would not have been possible.

This work was supported in part by a grant from the U.S. National Science Foundation and by the U.S. Antarctic Research Project.

GEOPHYSICS

Unusual Fluctuations of 5577A OI Airglow Emission Intensity on October 28–29, 1961

In a recent article, Kidd, Silverman, Whitney and Aarons[1] reported an unusual inversion of the frequency dependence of radio star scintillations during the magnetic storm of October 28, 1961. It is the purpose of this communication to report on the unusually large fluctuations in the 5577*A* *OI* airglow line intensity during the same period.

The October 28, 1961, event was unusual in that there was no obvious connexion with solar activity[2]. During October several class-2 flares and no class-3 flares were reported. The latest class-2 flare, however, was on October 16. Class-1 flares were reported on October 20 and 27. Some Type III solar radio bursts were reported for October 27 and 28. Magnetic storms were reported on October 26 (1940 *Z*) and October 28 (0812 *Z*) and during this latter storm K_p was as high as 8 and 9. A Forbush decrease is evident on the Deep River neutron monitor cosmic ray counter on October 28.

The airglow data were obtained at Sacramento Peak, New Mexico (geographic lat. 32°43′ N., geomagnetic lat. 41.6° N.), using a birefringent photometer as part of a routine airglow observing programme. Measurements of the green line are normally taken every 10 min. Fig. 1 shows the green line zenith intensity during the night of October 28–29, 1961 (all times are 105° W.M.T.), as well as, for comparison, the more typical night of October 21–22, 1961. It will be noted that the intensity fluctuations for October 28–29 are very marked, and are, in fact, unusual in that no such marked variations have previously been noted. The intensity variations were sufficiently rapid that even during the 36 sec. that the photometer is in the zenith position a variation by as much as a factor of two was observed. In order to be able to make some quantitative comparison of the intensity fluctuations during this night with other nights a fluctuation index equal to $\Delta I/\bar{I}$, where ΔI is the difference between the maximum and minimum values for a given time period and $\bar{I}$ is the mean intensity for this period, was defined, analogous to the scintillation index used in radio star scintillation work. This fluctuation index was calculated for all nights between September and December 1961 for which observations were available, a total of 75 nights. The time-period 2100–2300 hr. was chosen to reduce the effects of the normal diurnal variation on the index and still allow for sufficient experimental points to make the index significant. It was found that the fluctuation index for October 28–29 was at least 1.5 times as high as that for any other night during this four-month period, and greater than most nights by a factor of three to seven, thus emphasizing the unusual nature of the fluctuations for this night.

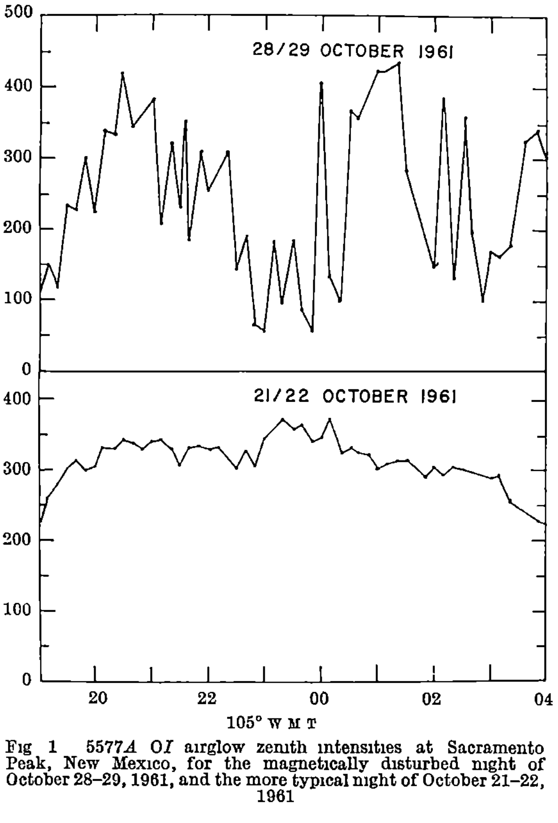

Fig. 1. 5577*A* *OI* airglow zenith intensities at Sacramento Peak, New Mexico, for the magnetically disturbed night of October 28–29, 1961, and the more typical night of October 21–22, 1961

Kidd *et al.*[1] state that localized multiple ionospheric small-scale irregularities of high electron density are responsible for the scintillations. They feel that the irregularities probably start at the *E*-layer and extend to greater heights aligned along the Earth's magnetic field. The airglow data are consistent with a picture of highly localized density variations. Emission of the green line takes place at the 90–100 km. level. The mechanism for production of the normal airglow emission does not involve electrons, but is quite sensitive to the concentration of oxygen atoms, if the Chapman mechanism is valid. Hence, a high degree of inhomogeneity of the atmosphere, as indicated by the radio star scintillation results, would lead to considerable patchiness of emission with resulting marked fluctuations in the zenith intensities, as is observed. The airglow data tend to support a greater than normal inhomogeneity at the lower heights since the 6300*A* *OI* emission, which occurs at a much greater height (of the order of 250–400 km.), showed fluctuations on October 28–29 of a sort which have been observed on a number of magnetically disturbed nights which did not show correspondingly high green line fluctuations. Parenthetically, it may be pointed out that normally for a magnetic storm of the magnitude observed on October 28 the red line shows a definite enhancement to the north[3], corresponding to auroral activity, while on this night no such enhancement was observed.

Examination of the airglow fluctuation index for other nights for which the radio star scintillation inversion effect has been noted (Aarons, J., private communication) shows that the fluctuation index is higher on these nights than on neighbouring nights, indicating that a real correlation exists between the two phenomena It must be pointed out, however, that the airglow fluctuation index, as here defined, may be expected to be sensitive to a number of factors These would include instrumental factors, observing conditions, the normal diurnal variation, patchiness of the airglow, and vertical transport Additional work is now in progress to define the effects of these factors on the fluctuation index and to examine other possible indices which may be more suitable for comparison with other upper atmospheric parameters

In summary, then, we may say that very unusual fluctuations of the 5577*A* *OI* airglow emission intensity were noted on October 28–29, 1961 The phenomenon is consistent with the picture of small-scale irregularities at *E*-region heights obtained from studies of radio star scintillations during the same day A fluctuation index has been defined which enables a semiquantitative comparison of the fluctuations for different days to be made Examination of the fluctuation index for other days on which the radio star scintillation inversion effect was noted shows that a correlation probably exists between the occurrence of the inversion effect and a high airglow fluctuation index

I thank Dr J Aarons for directing my attention to the radio star scintillation investigations and for many helpful discussions Acknowledgments are also due to personnel of Geo-Science, Inc, for the operation of the Sacramento Peak photometer and the scaling of the charts

PHYSICS

Relationship between Viscous Flow and Diffusion

A MOST peculiar paradox in the general area of viscous flow and diffusion is the fact that while the absence of slip between the surface of very large diffusing particles and the surrounding medium is usually taken for granted, at the same time in the case of diffusing particles that are identical as those of the medium, that is, in self-diffusion, it is the presence of slip between the 'diffusing particles' and the 'medium' which is a triviality It amounts to nothing more than the generally accepted fact that in a fluid the molecules are in translatory motion and, hence, move past each other However, in those cases of diffusion where neither of these two extreme situations is encountered the question as to the presence or absence of 'slip' does not always appear to be a trivial one

For the case of highly dilute solutions of very large particles the theory is generally regarded as well founded As, among others, H C Longuet-Higgins[1] pointed out, the Stokes–Einstein relation

$$D\eta = \frac{kT}{6\pi a} \tag{1}$$

is "one of the most soundly based relationships in the whole theory of transport phenomena" As is well known, in the derivation of equation (1) the medium was assumed to adhere to the surface of the diffusing particles and hence the only intrinsic friction coefficient in this equation is that between the solvent molecules

Expressions of essentially the same form as equation (1) have been suggested[2–5] also for the case where the diffusing particles are of commensurable size as the molecules of the medium The fact that none of these relationships proved satisfactory is due, to a large degree, to the failure of these equations to allow for the presence of slip and, hence, friction between the diffusing particles and the molecules of the medium For example, if one expects an expression of the form of equation (1) to hold for a dilute solution of ethanol in benzene, where D is now replaced with the 'activity corrected' mutual diffusion coefficient, $\mathscr{D}_{12}$, and η is the viscosity of pure benzene, this is tantamount to proposing either that the intrinsic friction coefficient between the ethanol and benzene molecules is the same as that between benzene molecules or that there is no slip between the ethanol and the benzene molecules Neither of these propositions seems at all plausible The analogy between the physical situation for which the Stokes–Einstein formula was derived and the case of, say, a non-dilute solution of ethanol in benzene becomes even more remote In such solutions it has been customary to use the viscosity of the solution with either the 'activity corrected' mutual diffusion coefficient[2,3] or the self-diffusion coefficient[4], D_{ii} (i = 1,2), of either constituent One should not be surprised that such relationships did not, in general, behave in a similar fashion as the Stokes–Einstein relation

From the very important treatment by Lamm[6] of the relationship between the diffusion coefficients and certain intrinsic friction coefficients introduced in his theory there follows that, at least for binary mixtures of non-electrolytes consisting of molecules of similar sizes, the following relations hold

$$\mathscr{D}_{12} = \frac{RT}{\varphi_{12} + \varphi_{21}} \tag{2}$$

$$D_{11} = \frac{RT}{\Sigma\varphi_{11} + \varphi_{12}} \tag{3a}$$

and

$$D_{22} = \frac{RT}{\Sigma\varphi_{22} + \varphi_{21}} \tag{3b}$$

Here φ_{12} and φ_{21} is the friction coefficient between molecules of type 1 and 2 per one mole of 1 or 2, respectively, $\Sigma\varphi_{11}$ is the friction coefficient between molecules of type 1 and 1 per two moles of 1, and $\Sigma\varphi_{22}$ is the friction coefficient between molecules of type 2 and 2 per two moles of 2

In the case of no slip between molecules 1 and 2, equations (2) and (3) must evidently be given a modified interpretation However, one would expect the above interpretation to be the correct one in a large number of binary mixtures For these one can calculate the molar friction coefficient η^* in the solution

$$\eta^* = N_1(\varphi_{12} + 1/2\,\Sigma\varphi_{11}) + 1/2\,N_2\,\Sigma\varphi_{22} = \frac{RT}{2}\left(\frac{N_1}{D_{11}} + \frac{N_2}{D_{22}}\right) \tag{4}$$

where equations (2) and (3) have been used

On the other hand, the viscosity of a fluid is the friction coefficient per unit area in the plane of shear multiplied by δ, an average distance between the centres of molecules such that touch each other (or collide with each other), measured in the direction perpendicular to the plane of shear Thus the following relationship has been obtained between η and η^*

$$\frac{\eta}{\eta^*} = \frac{\delta^2}{V_m} \qquad (5)$$

where V_m is the molar volume of the solution Equation (5) via equation (4) is the correct relationship between the viscosity and the diffusion coefficients of mixtures where there is 'slip' between molecules of type 1 and 2 as well as between 1 and 1, or 2 and 2 Equations (4) and (5) apply equally to liquids and gases, to mixtures and pure fluids Their extension to multi-component mixtures appears immediate If applied to pure gases, use of the elementary mean-free-path formulæ for η and D_{11} gives, as expected, the well-known value of 2/3 λ for δ (λ is mean-free-path) However, δ is equally meaningful in the case of liquids as well as gases

Using equations (4) and (5), δ has been calculated for pure liquids and binary solutions where the necessary experimental data are available These include the systems ethyl iodide–butyl iodide, nitromethane–carbontetrachloride, nitromethane–benzene, benzene–bromobenzene, methanol–benzene, ethanol–benzene, and sucrose–water In all the cases investigated the value of δ/r_{av} was found to be between 1 and 1 3 (r_{av} is average molecular radius) at all compositions of the solutions For the truly spherical molecules of argon and mercury this value was 1 24 and 1 27, respectively This result can be shown to be consistent with Bernal's[7] theory of the structure of monatomic liquids where the centres of all neighbouring atoms were assumed to be equidistant The average separation (δ) of planes passing through adjacent atomic centres in such a liquid can indeed be expected to be in the neighbourhood of 1 3 r

The foregoing results indicate identical mechanism of diffusion and viscous flow in the solutions investigated (No such conclusion can be reached for the sucrose–water system which, owing to the great size difference between sucrose and water molecules, probably does not qualify in this treatment) A further important consequence is the fact that, contrary to the widespread view held by many authorities in the field, the 'kinetic units' in such associating solutions as the methanol–benzene and the ethanol–benzene systems are the single molecules The 'anomalous' concentration dependence of $\mathscr{D}_{12}$ in these solutions could be interpreted by realizing that the friction coefficients in equations (2) and (3) are proportional to the areas of contact between the various kinds of molecules φ_{12} and φ_{21} are proportional to the fraction of the surface area of a molecule 1 and 2 that, on the average, is in contact with molecules 2 or 1 respectively $\Sigma\varphi_{11}$ and $\Sigma\varphi_{22}$, on the other hand, are proportional to the fraction of the surface area of a molecule 1 and 2 that, on the average, is in contact with other molecules 1 or 2, respectively Now, in associating solutions these fractions are very different from the random case, resulting in different concentration dependence of the friction coefficients and, hence, the diffusion coefficients

A further consequence of the present results is the fact that there does not seem to exist an exact relationship between the viscosity and the mutual diffusion coefficient in mixtures consisting of molecules of comparable sizes This fact is evident from equations (4) and (5), which do not involve $\mathscr{D}_2$ For regular or ideal solutions one has in a good approximation[4]

$$\mathscr{D}_{12} = N_2 D_{11} + N_1 D_{22} \qquad (6)$$

and this explains the well-known fact that for such solutions $\eta \mathscr{D}_{12}$ varies but little with composition (cf equation (4)) But this obviously constitutes a special case, an exception

Internal Friction of Glass under High Strain

IT is now known that, if proper care is taken over surface treatment, specimens of certain types of glass can be made which will withstand a strain of at least 5 per cent without failure It is of interest to investigate whether any of the physical properties of glass change when it is subjected to these high values of strain

In this communication, some experiments are described which show that the internal friction of glass increases by a considerable factor when subject to a high torsional bias strain Samples of 3 mm rod of *X*8 glass (a soda-lime glass) were drawn down in the centre so as to form a portion of approximately constant diameter of about 400µ The samples were treated by etching in hydrofluoric acid so that the thin portions would withstand a surface strain of 3–4 per cent Pairs of these samples, chosen to have similar minimum diameters, were then joined together end to end and an inertia disk was attached to the central thick portion of the resulting specimen A torsional bias stress was applied to the specimens by twisting one end relative to the other and then clamping both ends The logarithmic decrement of torsional oscillations of the central inertia disk was measured as a function of the torsional bias strain The observations were made at room temperature, and the frequency of the oscillations was of the order of 1 c /s

In the case of both chilled specimens and specimens which had been heat-treated for 12 hr at 530° C , the logarithmic decrement increased with bias strain An example typical of the results is shown in Fig 1, where the logarithmic decrement is plotted against the maximum value of strain on the specimen, namely, that at the surface of the section of minimum diameter The logarithmic decrement was corrected for air damping by performing an auxiliary experiment with a fused silica fibre and the same inertia disk Thus the corrected value refers only to that part of the damping which is due to internal friction in the *X*8 glass Since the glass is not under homogeneous strain the internal friction as a function of strain cannot be deduced from the results directly.

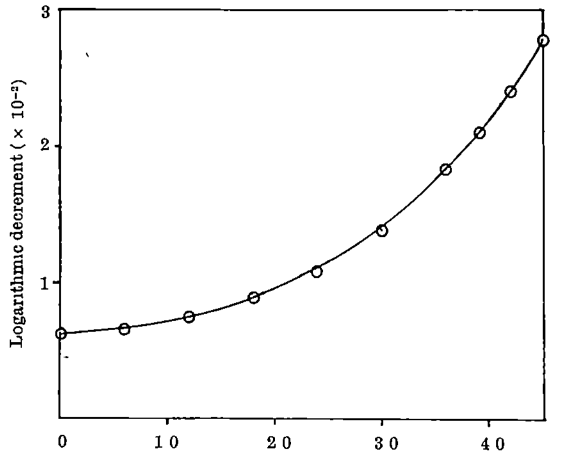

Fig. 1. Logarithmic decrement of torsional oscillations of heat-treated *X8* glass as a function of torsional bias stress

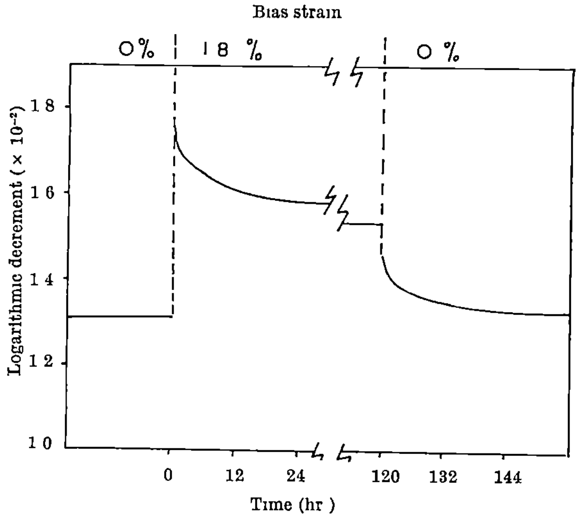

Fig. 2. Variation of logarithmic decrement with time after application and after removal of a torsional bias stress

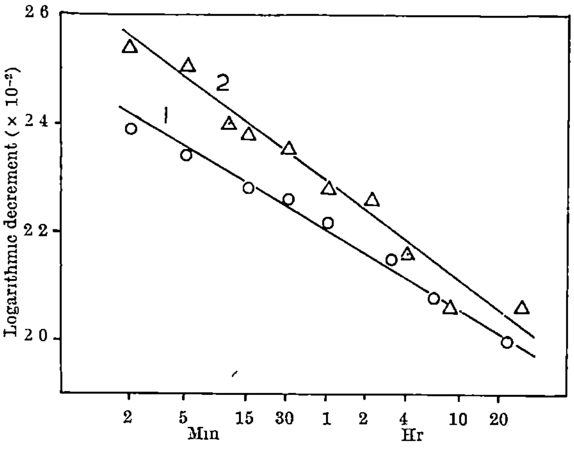

Fig. 3. Variation of logarithmic decrement with time under torsional bias stress. Curve 1, strain 2.3 per cent, clockwise twist, immediately after a period when the specimen was unstrained; curve 2, strain 2.3 per cent, clockwise twist, after 24 hr immediately preceding at 2.3 per cent strain, anticlockwise twist

However, it seems likely that it increases in a similar fashion and by an even larger factor.

The value of logarithmic decrement was also found to depend on previous mechanical history. Some examples of this phenomenon are shown in Figs. 2 and 3. In Fig. 2, it is seen that the value of logarithmic decrement decreases with time after the application of a bias stress. Moreover, if the specimen is later released to zero bias stress, the logarithmic decrement takes up a value which is higher than the initial zero-stress value, and then decreases gradually with time. Fig. 3 shows that the logarithmic decrement under torsional bias stress is higher immediately after a period when the specimen was twisted in the opposite direction than immediately after a period when the specimen was unstrained.

'Pyrex' glass also shows an increase in internal friction with torsional bias strain and shows similar relaxation of the values with time after straining.

Investigations into these phenomena are continuing with a view to determining the actual variation of internal friction with strain and the dependence of this variation on temperature.

CRYSTALLOGRAPHY

Preparation of Single Crystals of Cadmium Oxide

ELECTRICAL measurements on cadmium oxide have hitherto been made on thin layers[1], prepared by oxidizing an evaporated cadmium-metal layer or on ceramic samples[2-4]. So far as I know, single crystals have never been made. The preparation of such crystals is described in this communication.

If cadmium oxalate is heated it decomposes in the same way as the more-or-less noble metal oxalates, that is to say, following the reaction

$$CdC_2O_4 \rightarrow Cd + 2CO_2$$

When heating the oxalate in air the cadmium is oxidized immediately after it is formed. When there is no oxygen present, however, cadmium metal is formed.

On this reaction a method was based of growing single crystals of cadmium oxide. The oxalate was placed in a closed alumina vessel, in which a small hole was made. The vessel was placed in an electric furnace, which was heated at about 650° C. During the reaction the temperature was kept constant within 0.1° C. A stream of air was passed over the boat. As soon as the boat is placed in the hot furnace the oxalate starts to decompose, and the carbon dioxide which is liberated drives out the air. Only when the reaction comes to an end can air diffuse through the small hole and react with the cadmium vapour present. It is found that needles of cadmium oxide grow from the inside of the hole. By regulating the temperature needles of maximum 1 mm × 1 mm × 12 mm were obtained, which are very suitable for electrical measurements.

Cadmium oxide has the rock-salt structure. X-ray diagrams revealed that the needle axis is the [111]-direction. For the lattice parameter at 20° C a value of $a = 4.6949$ Å was found.

The stoichiometric composition of the crystals can be influenced by heating them at different temperatures in air or oxygen, or by heating in a closed quartz tube in which a definite cadmium pressure is maintained.

Note added in proof. In a recent paper, Haul and Just[5] mention the preparation of cadmium oxide crystals by gas-phase oxidation of cadmium metal.

Selective Epitaxial Deposition of Silicon

Epitaxial layers of silicon have been prepared by the hydrogen reduction of silicon tetrachloride at raised temperatures[1,2]. The rate of deposition of silicon is dependent on the total gas flow-rate, the molecular percentage of silicon tetrachloride in the hydrogen and on the silicon substrate temperature.

In this work the silicon substrates, after being chemically polished in a mixture of nitric, acetic and hydrofluoric acids, were placed on an electrically heated graphite electrode supported in a horizontal quartz tube. The substrates were heated to 1,200° C., and a 0·02 molecular ratio of silicon tetrachloride to hydrogen was used in all experiments. The gas composition was obtained by bubbling the hydrogen through silicon tetrachloride, maintained at 10° C., and further dilution with hydrogen provided the required molecular ratio. Conductivity type and required resistivity value of the epitaxial silicon were controlled by adding suitable quantities of phosphorus trichloride and boron tribromide to the silicon tetrachloride.

Oxide layers of various thicknesses were produced on the silicon substrate surface by heating the samples in an atmosphere of steam at different temperatures[3]. Windows were produced in the oxide layers by masking with photo-resist and etching away the unmasked areas[4]. By this means an oxide mask is produced directly on the substrate surface.

Prior to deposition the oxide-masked substrates were thermally etched in hydrogen for 10 min. at 1,200° C. This procedure removes the thin oxide layer present on the unmasked silicon surface[1], presumably by reducing it to silicon monoxide, which is volatile at 1,200° C.

The silicon substrate temperature is maintained at 1,200° C. and the silicon tetrachloride–hydrogen mole fraction at 0·02, therefore the sole factor affecting the rate of deposition of silicon is the gas flow-rate. Using a gas flow-rate of 4 l./min. a polycrystalline silicon deposit was formed on the oxide layer and a single crystal deposit where the oxide layer had been removed (Fig. 1). The polycrystalline deposit was not satisfactorily removed by ultrasonic etching in hydrofluoric acid, which should attack the underlying oxide layer. Oxide masks up to 30,000 Å. thick were used in these experiments.

On decreasing the gas flow-rate it was found that the amount of polycrystalline silicon on the oxide layer also decreased. At flow-rates below 1 l./min. virtually no polycrystalline deposit is formed on the oxide mask, while epitaxial silicon continues to grow on the unmasked areas.

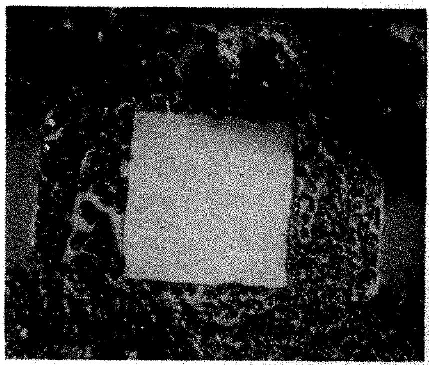

Fig. 1. Single crystal silicon deposit on 0·050 in. × 0·050 in. unmasked area. Polycrystalline deposit on surrounding oxide mask

Examples of these selective depositions are shown in Figs. 2 and 3. The substrate surfaces are perpendicular to the [111] crystal axis. Although the epitaxial deposits are only approximately 5μ thick they are bounded by small facets shown clearly in Fig. 2. These facets are probably characteristic of growth in the [111] direction.

Selective deposition of epitaxial silicon layers has been obtained at low gas flow-rates using oxide masking techniques. Under these conditions the rate of nucleation of polycrystalline silicon has been minimized on the oxide layer, and it appears that the rate of nucleation is greater on the silicon than on the silicon dioxide surface. This may be due, in part, to the fact that the rate of nucleation of silicon on the oxide layer has to compete with the rate of reduction of the oxide surface in a hydrogen atmosphere to form the volatile silicon monoxide. It is very probable that at 1,200° C. any silicon nucleating on the silicon dioxide surface will react with it to form silicon monoxide, according to:

$$Si + SiO_2 = 2\ SiO$$

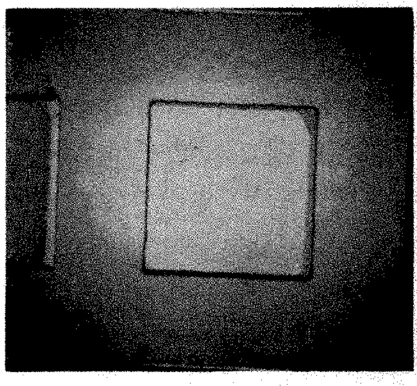

Fig. 2. Selective epitaxial silicon deposit on 0·050 in. × 0·050 in. window in oxide layer

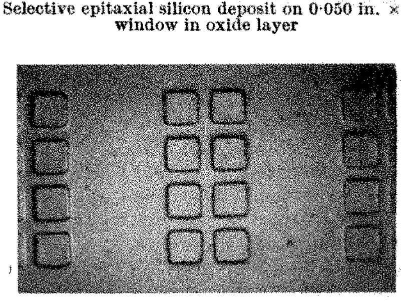

Fig. 3. Selective epitaxial deposits on 0·009 in. × 0·009 in. oxide-layer windows

This latter reaction, however, is not the complete explanation of the masking phenomena. If one assumes that the same quantity of silicon is deposited on the oxide surface as on the silicon surface then, for satisfactory selective deposition, the thickness of single crystal silicon must not exceed the oxide layer thickness. In these experiments it has been possible to deposit selectively silicon layers up to 25μ on oxide layers of thickness 3μ.

The most satisfactory explanation for selective deposition is that, at low flow-rates of gas, the rate of deposition of silicon atoms on a silicon surface is far greater than the rate of nucleation of silicon on a silicon dioxide surface. On increasing the flow-rate, however, the rate of nucleation on the oxide surface will increase considerably and no selective depositions are obtained. This phenomenon is now being investigated. For semiconductor devices this technique offers advantages in that 'mesa'-structures can be produced on a silicon slice to the desired size and at the required place. For multiple devices, leads can be evaporated on to the surface of the oxide and will not come into contact with the bulk of the silicon slice. By a suitable choice of substrate and of epitaxial film resistivities, further heating of the sample will cause diffusion of the impurities so as to bring the junction below the oxide layer, with the consequent advantage of low leakage currents, as is found with planar devices.

MINERALOGY

Orientation of OH Bonds in Kaolinite

INFRA-RED spectroscopy has been found to be a useful method in establishing the orientation of OH bonds in layer silicates[1]. In micas and related forms of crystallization, the orientation of the OH depends on the occupancy of the octahedral positions. In trioctahedral compositions, the OH bonds are normal to the flakes and these groups are free of association in any supplemental bond (absorption band at 3,700 cm.$^{-1}$). In dioctahedral minerals, the OH are inclined about 20° to the plane of the flakes and directed to the unoccupied octahedra; the absorption band is observed at 3,620 cm.$^{-1}$, which indicates some degree of secondary association.

Previous attempts to establish the orientation of OH groups in kaolinite, with a greater population of OH than the mica substances, were not conclusive[1,2], but data on dickite by Newnham[3] and on kaolinite by Fripiat and Toussaint[4] strongly indicated that oriented specimens could be successfully prepared and analysed. This communication reports a successfully analysed oriented aggregate.

The sample of kaolinite was dispersed in water and after sedimentation the fraction < 1μ was taken. A plate of 'Irrtran-2, disposed horizontally, was immersed in the suspension. After 24 hr., the plate with the sedimented kaolinite particles was removed and allowed to dry at room temperature and afterwards at 100° C.

Fig. 1 presents the infra-red spectra of the oriented kaolinite for different incidence angles. In Fig. 2 the spectrum of an unoriented sample obtained by the potassium bromide disk technique is given for comparison.

The kaolinite shows four absorption bands at 3,695, 3,670, 3,650 and 3,620 cm.$^{-1}$. The band at 3,695 cm.$^{-1}$ presents a marked increase in intensity with increasing angle of incidence and must correspond to OH bonds in a direction near normal to the flakes. These OH's must be almost free; that is, not participating in any significant hydrogen bonding association. However, this band is relatively wide, which suggests that the unassociated OH bonds are of at least two not quite equivalent energies.

The 3,620 cm.$^{-1}$ band, by analogy with the results obtained in micas, must be assigned to OH directed to the unoccupied octahedra. This allocation is substantiated by the observation that the magnesium minerals analogues (serpentines) do not show this absorption (Fig. 3).

The other absorptions at 3,670 and 3,650 cm.$^{-1}$ must correspond to OH which are participating in hydrogen bonding between layers. These bonds will be very weak.

The magnitudes of the absorption coefficients at the four positions where absorption is maximal indicates that free OH with axes near normal to the plane of the flakes comprise about half the total population, bonds directed toward unoccupied octahedra make up only about a fourth, and no more than a fourth

RADIATION CHEMISTRY

Radium α-Activity of Cigarette and Pipe-Tobacco Ash

During the course of a series of measurements of the radium content of natural waters and coal in New South Wales[1], we made some analyses of tobacco Two packets of Australian-made cigarettes and one 2 oz tin of pipe tobacco (Australian made, English blend) were taken at random The ash was fused with alkali carbonate the mixture was neutralized and then silica was removed by filtration The filtrate was then analysed for radium by Goldin's radiochemical method[2]

The cigarettes (including paper but excluding filters) and tobacco were ashed over a Meker burner Part of the ash (1 gm) was fused with sodium carbonate (10 gm), the melt was dissolved in distilled water, which had been passed through a mixed ion-exchange bed, and the solution was acidified with hydrochloric acid After evaporation to dryness, and baking, the silica was removed and the filtrate was almost neutralized with ammonia Citric acid was added to the solution and also lead and barium nitrate scavengers Radium isotopes are isomorphously carried with the mixed sulphates obtained by precipitation with dilute sulphuric acid Further purification followed from co-ordination with ammoniacal ethylenediamine tetraacetic acid and preferential decomposition of the barium complex A small residue of barium sulphate, containing radium, was then transferred to a stainless-steel planchette for measurement of its α-activity An argon gas flow-proportional counter of the Sharp Atomic Energy Research Establishment, Harwell, design was used with an efficiency of 25 6 per cent at an operating voltage of 1 05 kV as determined by calibration with 1 mgm natural U_3O_8 (ref 3) Self-absorption corrections were also made from measurements on barium sulphate samples of varying weights The α-activity does not change with time in the same way as can be expected of radium-226 and its daughters and it seems that other α-emitting radioisotopes are present, probably radium-223 and radium-224 (refs 2, 4), although radium-226 is likely to be predominant

Results of the analyses are given in Table 1

We have obtained larger radium activities from analysis of larger samples in the expectation that

Table 1. RADIUM α-ACTIVITY OF TOBACCO

Sample	Total ash (gm.)	Total activity* (c./min.)	Total activity (μμc.)	Activity/gm. ash (μμc.)	Activity per cigarette (μμc.)
Packet *A* (20 cigarettes)	1.75 (8.62)†	5.8 ± 0.02	10.2	5.8	0.5
Packet *B* (20 cigarettes)	1.75 (8.62)	7.2 ± 0.02	12.7	7.3	0.6
Pipe tobacco					
Sample *A* (25 gm.)	2.42 (9.69)	3.8 ± 0.01	6.7	2.7	
Sample *B* (25 gm.)	2.42 (9.69)	4.1 ± 0.01	7.2	3.0	

* Measurements of radium in the reagents gave no α-activity distinguishable from the normal counter background, 0.46 c./min. The total count-rates were constant for one day after the separation of radium on barium sulphate. Ingrowth or decay factors are not included.

† Ash content of tobacco is shown as a percentage in parentheses.

α-pulse analysis will enable us to distinguish the various isotopes present.

We wish to acknowledge the subsidy provided by the Sydney City Council for the provision and operation of the Trace Radioactivity Laboratory, in which this work was done.

CHEMISTRY

Free Electrons with Thermal Energy: their Generation for Chemical Use

FREE electrons with thermal energy react readily with the molecules of many chemical substances, since the free electron may be regarded as the simplest free radical, an unattached valence bond, and indeed as an ultimate chemical particle, this reaction is clearly of interest and importance in chemistry. The lack of a source of uncontaminated free electrons at thermal energy has restricted the observation of free electron reactions to systems where the free electrons were present simultaneously with other reactive species such as free radicals, positive ions, excited atoms and molecules, and ionizing radiation. Some or all of these reactive contaminants are present in the reactions of radiation and electro-chemistry.

This communication describes a simple apparatus for the generation of a flux of uncontaminated thermal energy electrons. The electron source is designed specifically for chemical use and provides an electron flux sufficient to produce reaction products in quantities adequate for chemical measurements.

Primary electrons set free from matter are almost always at a high temperature, this is because their separation requires the application of intense electrical fields, heat or energetic radiation. These relatively severe conditions also tend to liberate other active particles including atoms, radicals, negative and positive atomic and molecular ions. The problem of designing a source of pure thermal electrons is principally that of separating the primary electrons from contaminating particles and then cooling them to normal temperatures. For chemical use it is most convenient to dispense thermal electrons in a flow of inert gas at normal temperature and pressure.

There are two reliable methods of setting free electrons from a gas at N.T.P.: a corona discharge or the application of ionizing radiation. Thermionic or photoelectric electron sources which are frequently used in physical studies are generally unreliable in a chemical environment where the poisoning of the electron-emitting surface can readily occur. The best inert carrier gases for free electrons are the noble gases; in one of these gases the application of a corona discharge or of ionizing radiation produces, as long-lived products, only free electrons and positive atomic ions; these are readily separated from one another by the applied electrical field. Even in the presence of a weak electrical field, however, a mixture of free electrons and noble gas atoms is far from isothermal, since the electrons have little opportunity to lose the energy they gain from the field during their elastic collisions with the relatively massive noble gas atoms. Cooling to thermal equilibrium is achieved by introducing into the noble gas stream, after the primary separation of the electrons, a flow of polyatomic gas such as carbon dioxide or methane; non-elastic collisions between the electrons and either of these gases soon reduces their temperature to thermal equilibrium with the supporting gas mixture.

Fig. 1 illustrates the dimensions and materials of construction of a corona discharge thermal electron source. The corona discharge is maintained at the tip of a No. 0 sewing needle by the application of a negative potential of between 6 and 30 kV. The needle is mounted coaxially inside a polytetrafluorethylene tube of 3 mm. internal diameter through which argon is flowing at a rate of 100 ml./min. Approximately 5 mm. beyond the needle tip the polytetrafluorethylene tube enters a larger tube of the same material (1 cm. internal diameter) into which a gentle stream of carbon dioxide at 1 ml./min. is flowing. After flowing through 2 or more cm. of this larger tubing, the electron stream is allowed to react with the test material. The negative charge conveyed to the test material by the electron stream is led to ground potential either through an inert electrode such as a sheet of platinum foil, or where it is important to avoid the possibility of anode reactions through a well-defined electrode such as silver, silver chloride in 1.0 *M* potassium chloride.

In use the potential required depends on the conductivity of the test material, the electron flux needed and the distance between the needle point and the surface of the test material. Up to a current flow of 30 μamp. a stable corona discharge is easy to maintain. At higher currents up to 200 μamp. care must be taken to ensure that a streamer type discharge does not take place. With such a discharge the test material would be exposed to high-energy electrons and to positive ions.

The detailed results of the use of this apparatus will be described elsewhere; however, a brief account of some of the experiments with the electron source are given as follows to illustrate its potentialities.

Substances such as bromo- or nitro-benzene in the pure dry state have a negligible ohmic conductivity, nevertheless they appear to offer no appreciable resistance to the flow of free thermal electrons. With bromobenzene the reaction with electrons appears to be that of dissociative capture since a stoichiometric yield of bromide ions can be collected from the anode compartment. Alternate intermediates of the Krebs's cycle are known to react vigorously with

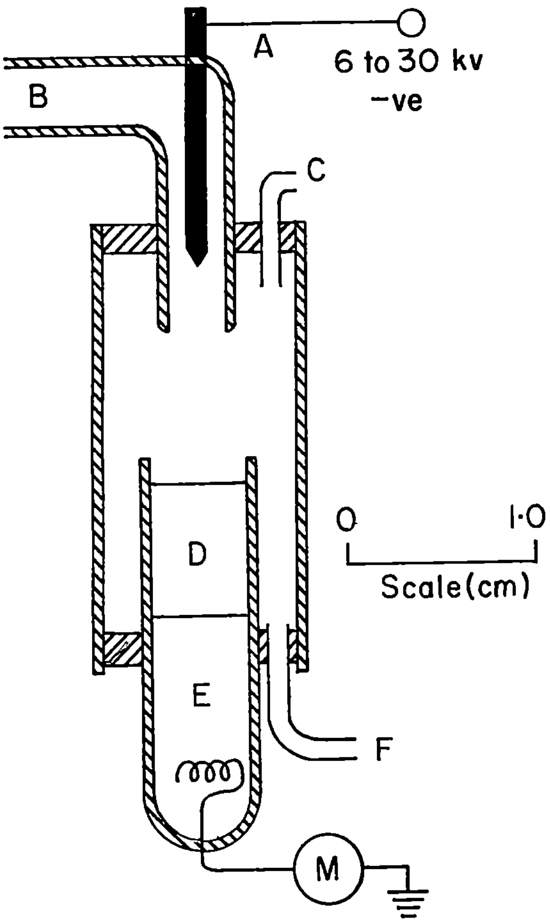

Fig 1 Generator of free electrons with thermal energy The apparatus is constructed from polytetrafluorethylene tubing and the dimensions are indicated by the scale included on the diagram *A*, a No. 0 sewing needle, *B*, inlet for argon gas, *C*, inlet for carbon dioxide, *D*, test material, *E*, 1 0 *M* potassium chloride solution containing a silver, silver chloride electrode, *F*, gas outlet, *M*, 0–100 µamp meter

thermal electrons[1], the determination of the nature and products of this reaction is potentially important to the understanding of the biological process of oxidative metabolism, particularly in connexion with the function, if any, of free electrons in this system A layer of diethyl fumarate was exposed to free electrons in the apparatus illustrated in Fig 1. After several hours the products in the remaining ester layer and in the potassium chloride solution of the electrode compartment were analysed, it was found that, for each electron added, approximately 30 molecules of fumarate were removed and that the principal products were succinate, oxalacetate and malate It is interesting and significant that the injection of free electrons did not lead simply to reduction products, but rather it would appear initiated in the presence of water a radical chain reaction, the products of which were the same as those of the biological process of oxidative metabolism

In addition to reaction studies the apparatus described may also be used for the measurement of electron absorption coefficients and electron affinities in the liquid phase In this type of application it is usually preferable, however, to use soft β-radiation to set free the primary electrons, a corona discharge is normally too 'noisy' for precise measurements

Methylhydroperoxide and the Slow Combustion of Methane

It has generally been assumed that in the uncatalysed slow combustion of methane at below atmospheric pressure (temperature-range ~ 400°–700° C) peroxides, other than hydrogen peroxide, play no part and the reaction between methyl radicals and oxygen is

$$CH_3 + O_2 \rightarrow CH_2O + OH \text{ (ref 1)}$$

We have investigated the oxidation at about 400° C catalysed by the photo-decomposition of acetone With a new quartz vessel (HF-treated) no peroxides were detected in the products However, after the vessel had been in use for about a year they were found to contain very appreciable quantities (~ 10 per cent carbon combusted) of methylhydroperoxide, identified and determined approximately by paper chromatography[2] and vapour-phase chromatography Small amounts were present in the products of a subsequent uncatalysed oxidation, but the hydroperoxide yield fell below the limit of detection after 2–3 experiments, and then was also below this limit in a subsequent photo-catalysed reaction In further catalysed oxidations under standard conditions the yield gradually increased, though it remained small The yield of methanol also rose during this 'conditioning' process (~ 3 times), but in any particular combustion it only became appreciable after the concentration of formaldehyde had built up On addition of formaldehyde to the reactant mixture initially the alcohol was produced immediately

The decomposition of methylhydroperoxide in the vessel at 395° C gave formaldehyde, methanol, water and probably oxygen The half-life was roughly 30 sec when the surface had been 'conditioned' by photo-catalysed oxidations (the CH_2O/CH_3OH ratio in the products being about unity), and 5–10 sec when it had been 'aged' by uncatalysed slow combustions (the CH_2O/CH_3OH ratio being about 4) The half-life of CH_3OOH with respect to homogeneous decomposition must therefore be $\geqslant 30$ sec in between those of hydrogen peroxide and ethyl and higher hydroperoxides at the same temperature[3] This seems not unreasonable

The results indicate that, in these systems at around 400° C , most CH_3O_2 radicals probably abstract hydrogen from formaldehyde, after this has been formed in appreciable amounts, namely

$$CH_3O_2 + CH_2O \rightarrow CH_3OOH + HCO$$

(cf work on the photo-oxidation of azomethane at below 200° C)[4] The hydroperoxide decomposes heterogeneously, namely

$$CH_3OOH \rightarrow CH_2O + H_2O \text{ or } CH_3OH + \tfrac{1}{2}O_2$$

although some methanol may be formed homogeneously, namely

$$CH_3OOH \rightarrow CH_3O + OH$$

$$CH_3O + CH_2O \rightarrow CH_3OH + HCO$$

Thus the mechanism of the slow combustion of methane at relatively low temperatures may be more complex than considered previously[5].

Quantitative Determination of Bilirubin and other Tetrapyrrols

A REAGENT, 3-methyl-2-benzothiazolon-hydrazone hydrochloride (MBTH, supplied by Aldrich Chemicals Co., Inc., Wisconsin), synthesized in 1910 has recently been introduced in quantitative photometry for the determination of aliphatic aldehydes[1], and also for aromatic amines, imino-heteroaromatic compounds, certain azodyes, carbazoles, stilbenes, Schiff bases and pyrrole derivatives[2].

Only the steps involved in the reaction between MBTH and formaldehyde have been settled[1]. First, formaldehyde condenses with MBTH, and secondly, excess MBTH is oxidized by ferric-chloride to a reactive cation which afterwards condenses with the formaldehyde–MBTH complex to a strongly coloured cationic pigment.

Because MBTH reacts with certain pyrrole derivatives, investigations have been carried out to see if this reagent forms highly chromophoric bonds also with bilirubin and other tetrapyrrols. Three different reactions between 'bilirubin' and MBTH have been studied.

(*A*) MBTH reacts with purified bilirubin to give a pigment with a broad maximum at 635 mμ and an extinction coefficient (moles/l./cm.) of 119,000 compared with 60,500 for bilirubin dissolved in chloroform read at 454 mμ, and to 81,000 for bilirubin coupled with diazotized sulphanilic acid read in a strong acid solution at the 570 mμ maximum.

(*B*) Bilirubin is split into two dipyrrols when the tetrapyrrole reacts with diazotized sulphanilic acid. Theoretically, formaldehyde is released when the second dipyrrole couples. However, the excess diazo-reagent necessary to get a complete coupling seems to interfere and formaldehyde could not be detected with MBTH in the distillate.

(*C*) The azo-pigments of bilirubin separated from the reagents by adsorption to alumina oxide react with MBTH to give pigments which have their maximum absorption at 615 mμ with extinction coefficients near 80,000 moles/l./cm.

Oxidation products of bilirubin (biliverdin, urobilin) also react with MBTH to form strongly coloured products. The fraction of oxidized bilirubin present in a solution may, consequently, be determined because bilirubin and its oxidation products react with MBTH, while only bilirubin and mesobilirubin couple with diazotized sulphanilic acid.

Procedure for reaction A. A reaction mixture containing 0·5 ml. of bilirubin in chloroform, 4 ml. of isopropyl-alcohol and 1 ml. of 0·4 per cent MBTH in water is allowed to stand for 5 min at room temperature. The colour turns to blue-green when 1 ml. of 1·3 per cent of ferric chloride in 0·25 *N* hydrochloric acid is added. After 1 hr. the mixture is read in a spectrophotometer at 635 mμ against a blank without bilirubin.

π-Charge-Transfer Complexes of Hexamethylborazole

BORAZOLE has been described as inorganic benzene. It might be expected[1] that appropriately substituted borazoles would form complexes similar to the well-known π-molecular complexes of benzene and its derivatives[2]. Recently it has been observed[3] that mixtures of hexamethylborazole and tetracyanoethylene in chloroform show a broad featureless absorption band (λ_{max} = 561 mμ) not possessed by either component alone. It was suggested that hexamethylborazole, acting as an electron donor, forms a π-π-charge-transfer complex with the electron acceptor tetracyanoethylene. Other electron acceptors should also form such complexes with hexamethylborazole. Unfortunately complexes with hexamethylborazole are relatively weak: the association constant (K) for the tetracyanoethylene complex is 0·7 l. mole^{-1} in chloroform at 21°, compared with K = 27·6 l. mole^{-1} for the corresponding hexamethylbenzene complex. The only other similar interaction which was reported was with the electron acceptor chloranil. In this case, instability of the complex, and the position of the charge-transfer band which overlapped a transition of chloranil itself, made the definite determination of the charge-transfer band impossible.

We have now observed a broad absorption band in mixtures of hexamethylborazole with 2,3-dicyano-*p*-benzoquinone in chloroform (λ_{max} = 460 mμ), similar mixtures with 2,3-dicyano-5,6-dichloro-*p*-benzoquinone give an absorption with λ_{max} = 487 mμ.

Several workers have demonstrated the empirical linear relationship between the ionization potential (I_p) of the donor molecules and the frequencies of the charge-transfer bands of complexes of electron donors with a given electron acceptor[4]. This result is not immediately apparent from theoretical arguments[5]. Nevertheless the relationship has been shown to give consistent values of I_p for donors from the positions of the absorption maxima of complexes with several different acceptors[6]. Application of such a relationship to a series of complexes of donors of known ionization potential with 2,3-dicyano-*p*-benzoquinone gives I_p = 8·6 eV for hexamethylborazole, similarly from corresponding complexes of 2,3-dicyano-5,6-dichloro-*p*-benzoquinone, I_p = 8·6 eV. The earlier work with the tetracyanoethylene complex yielded a value of I_p = 8·5 eV.

Although it is not claimed that this method gives accurate values of the vertical ionization potential for hexamethylborazole, the consistency of I_p interpolated from λ_{max} for these three complexes of hexamethylborazole at least suggests that the observed optical absorptions are the result of intermolecular charge-transfer complex formation

Reaction of Fluoro-2,4-dinitrobenzene with Amino-Acids and Peptides

THE reaction of fluoro-2,4-dinitrobenzene with the terminal amino-group of peptides and proteins under mild alkaline conditions has been widely used for the quantitative assay of *N*-terminal amino-acids[1] In the corresponding reaction with amino-acids, it has been shown[2] that some 2,4-dinitrophenyl-peptide is formed, the proportion of the DNP-peptide increasing with the separation of the amino- and carboxyl-functions

A peptide linkage is readily formed between an *N*-substituted amino-acid DNP-ester and an amino-acid[3] and this mechanism could be responsible for DNP-polymer formation through the intermediate DNP-amino-acid DNP-ester

The bimolecular nucleophilic substitution of fluorine by a carboxylate ion should be related to the basicity of the anion present in the alkaline solution[4] The nucleophilic power of the attacking reagent would then increase with increasing value of pK_1 for the substituted amino-acid The reaction-rate is also influenced by the ion-pairing tendency of carboxylate ion in the substrate, following the same order of accelerating power as in the above sequence

O-dinitrophenylation would be more likely to occur in the presence of an excess of fluoro-2,4-dinitrobenzene than when an excess of amino-acid is present Increasing yields of DNP-amino-acid have been obtained by raising the concentration of amino-acid in the mixture[5], or raising the reaction temperature and evaporating the mixture to dryness[2] Once the DNP-amino-acid DNP-ester is formed, the reaction of this 'mixed anhydride' with a free amino-group would occur in competition with the reaction of fluoro-2,4-dinitrobenzene at the same amino-group

The intermediate DNP-amino-acid DNP-ester has now been isolated by paper chromatography of the products of reaction between fluoro-2,4-dinitrobenzene and β-alanine The products from a typical reaction are (R_F values in brackets), ethyl 2,4-dinitrophenyl ether (0 95), *bis*-2,4-dinitrophenyl ether (0·73), 2,4-dinitrophenyl-β-alanine 2,4 dinitrophenyl ester (0·63), 2,4-dinitrophenol (0 53), 2,4-dinitroaniline (0 46), 2,4-dinitrophenyl-β-alanine (0·26), 2,4-dinitrophenyl-β-alanyl-β-alanine (0 06), and 2,4-dinitrophenyl-di-β-alanyl-β-alanine (0 01) The solvent system was 95 per cent propanol, 95 per cent acetic acid and petroleum ether (b p 100–120°), (20 6 100 v/v), moving on Whatman No 1 paper buffered with 0 1 *M* citric acid Elution of the 'active ester' and subsequent reaction with β-alanine gave β-alanyl-β-alanine and 2,4-dinitrophenol A similar intermediate phosphate DNP-ester has been isolated, in high yield, from the reaction between a monophosphate ester and fluoro-2,4-dinitrobenzene in the presence of pyridine[6] This base must be excluded from reactions involving amino-acids, due to the concurrent ring opening of the intermediate pyridinium fluoride in the presence of a primary amino-group

The reaction of fluoro-2,4-dinitrobenzene with a series of ω-amino-acids, including aspartic acid and glutamic acid, also produced considerable amounts of DNP-polymers In the case of glutamic acid the identity of the polymers as γ-glutamyl peptides has been shown by comparison with authentic material prepared by the phthaloylglutamic anhydride procedure[7]. The corresponding α-glutamyl compounds were made from the acid chloride of phthaloylglutamic acid γ-methyl ester

In related reactions with glycine, glycylglycine, and diglycylglycine, the proportion of dimer was only significant with the latter compound, although the formation of DNP-glycylglycine from DNP-glycine has been reported[2] Observations on higher molecular weight starting material are rendered difficult by the low mobility of the DNP-polymers on chromatograms The results of these experiments are shown in Table 1

Table 1 DNP-POLYMERS FORMED BY REACTION OF MONOMER WITH FLUORO-2,4-DINITROBENZENE

Monomer	pK_1	No of monomer units in polymer 2	3	4	5
Glycine	2 34	trace	–	–	–
β-Alanine	3 60	+	+	+	trace
ε-Aminocaproic acid	4 43	+	+	+	+
Glutamic acid	2 19				
	4 25	+	+	trace	–
Aspartic acid	1 88				
	3 65	+	+	trace	–
Glycylglycine	3 12	+	trace	?	?
Diglycylglycine	3 26	+	?	?	?

Reaction of an excess of fluoro-2,4-dinitrobenzene with glutamic acid at *p*H 8 5 and 40°, washing with hexane followed by further reaction with glutamic acid, gave substantially increased yields of the DNP-γ-dimer with little of the higher polymers The free dipeptide was obtained by fast hydrogenolysis using a large excess of platinum catalyst, followed by extraction from the *m*-phenylenediamine produced[8] This reaction is now being applied to the synthesis of peptides containing aminoalkylphosphonic acid residues

Solid-State Polymerization of Phosphonitrilic Chloride

SINCE the work of Mesrobian *et al* [1] on the polymerization of acrylamide, many monomers have been polymerized in the solid state by γ-rays or electron beam[2–4] Hayashi and Okamura[5] have recently irradiated cyclic monomers and found that the rate of polymerization increases up to the melting point of

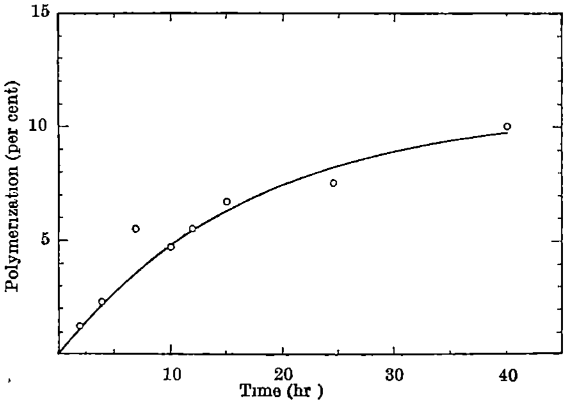

Fig 1 Polymerization of phosphonitrilic chloride at 100° C, induced by X-rays (dose-rate, 1 2 Mr /hr.)

the monomers and that polymerization occurs only in the solid state

Phosphonitrilic chloride has been polymerized thermally with and without initiator at temperatures above 200° C from the melt[6–9] Below this temperature the rate of polymerization is of a few per cent conversion per day An attempt to polymerize this monomer in the solid state by γ-radiation has failed to give any significant amount of polymer up to 10^6–10^8 rads[10]

More recently[11], phosphonitrilic chloride has been irradiated by 4 MeV electrons with doses of 10^9 rads at −70°, 25° and 120° C *in vacuo* In spite of the high dose, only a small amount (1–2 per cent) of an insoluble product was obtained under these conditions

We have now found that phosphonitrilic chloride does polymerize in the solid state when irradiated by 50-kV X-rays The rate of polymerization increases with temperature and has a maximum near the melting point (114° C) Irradiation has been carried out on freshly sublimed phosphonitrilic chloride (Albright and Wilson, Ltd) at a dose-rate of 1 2 Mr /hr The samples after irradiation have been washed thoroughly with petroleum ether to remove any unpolymerized material and the white product thus obtained has the appearance of the elastomer which is obtained thermally

Polymerization conversion at a given dose-rate increases with time of irradiation up to a certain value of the yield where a saturation phenomenon occurs as shown in Fig 1

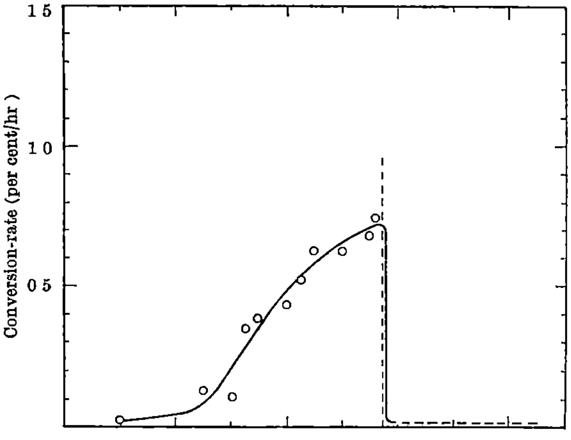

Fig 2 Effect of temperature on the polymerization of phosphonitrilic chloride (dose-rate, 1 2 Mr /hr , irradiation time, 10 hr)

The polymerization-rate is influenced by the presence of oxygen, the purity of the material and the size of the crystals

The increase of reaction-rate with temperature seems to be a common feature of the polymerization of cyclic monomers in the solid state As may be seen in Fig 2, the rate of polymerization reaches a maximum and then decreases almost to zero above the melting point This behaviour has been observed for cyclic siloxane[12] and for some organic monomers[5]

A mechanism which may interpret this behaviour has not yet been worked out It should explain if chains propagate by ions or free radicals and therefore if polymerization is somehow related to the species which may be more or less active near the melting point The drop of the polymerization-rate with fusion could thus be provoked by the fact that the active species may have a longer life-time in the solid state, being the recombination inhibited in these conditions

The structure of the solid may be, however, the determining factor for the polymerizability of the monomer An increase of temperature may, for example, allow favourable positions for the monomer molecules to grow

An investigation of the structure of the polymer in the solid monomer may very likely provide more information about the whole process An examination study of the X-ray rotation diagrams on a single crystal in various stages of polymerization is in progress in this laboratory

BIOPHYSICS

Time-dependence of the Radical State in an X-irradiated Keratin*

THE importance of biological solids as model substances for radiation reactions has grown considerably since the *milieu*-dependence of some radiation effects in solids has been demonstrated[1–5]. In this connexion the electron spin resonance investigation of X-irradiated keratin offers two additional advantages First it gives a broad characteristic signal, which is probably due to a sulphur-containing radical[6]. Therefore it should be possible to follow a single reaction in the solid, independently of other reactions which possibly may occur The second advantage is also based on the fact that the keratins contain a large amount of sulphur[7] Therefore it seems possible to obtain some information about radiation protection mechanisms from radiation experiments on keratins

Dried keratins (4 days over phosphorus pentoxide at 45° C , 6 per cent weight reduction) were irradiated with 2 8 Mrads (half-value layer 10 mm water) for 7 min. and the effect afterwards investigated in a laboratory-built X-band spectrometer[8] at different temperatures of the reflexion cavity. The cavity permanently contained a single crystal of copper sulphate, adjusted for maximum g-value. This permitted an intensity calibration of the spectrometer[9-11]

We found, as already mentioned in a preceding paper[12], a slow increase of the intensity in the low-frequency part of the keratin spectrum (Fig 1) up to saturation values of 130–150 per cent of the initial intensity (Fig 2) The ratio of A^x/B^x, which is a measure for the line shape, remains nearly constant during the observation time of 80 min

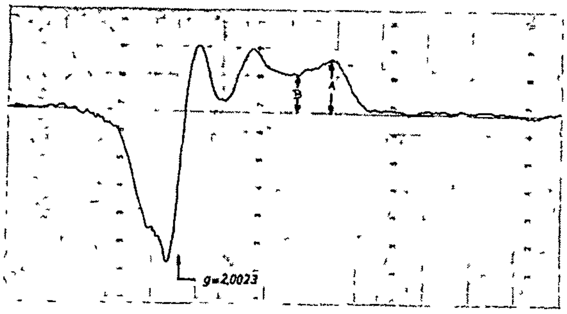

Fig 1 Electron spin resonance of X-irradiated feather quills at 9,523 mc /sec , 13 min after irradiation with 2 8 Mrads, dose-rate, 0 4 Mrad/min The transient line at the position of the free spin value is still present

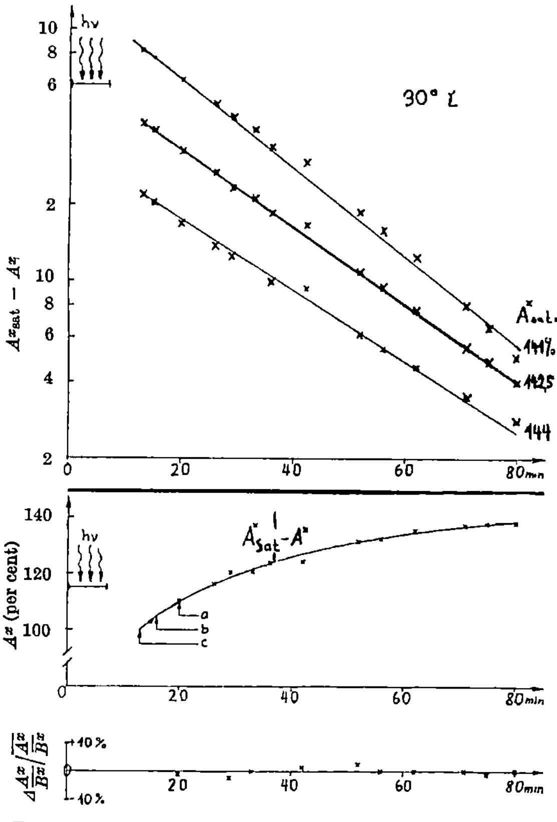

Fig 2 Time behaviour of the sensitivity-corrected value A^x of the amplitude A (cf Fig 1)

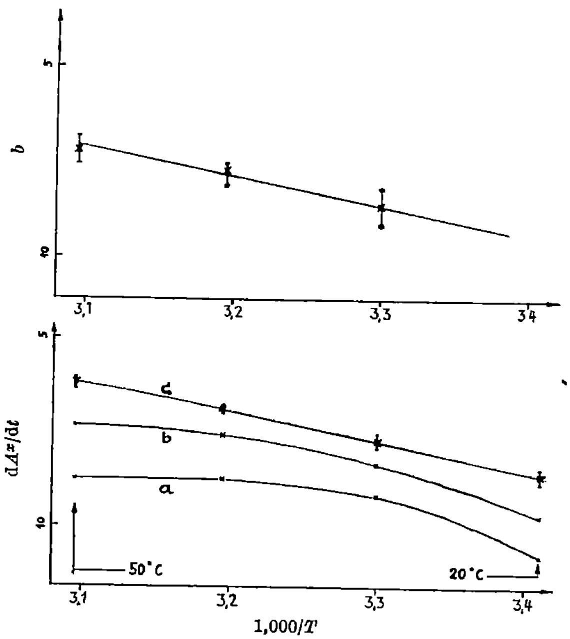

Fig 3 Rate constant b and reaction-rate dA^x/dt at three different times a, b, c versus reciprocal temperature

If A^x denotes the amplitude, A, in the keratin spectrum (Fig 1) related to the spectrometer sensitivity, we found at a first approximation the relation

$$\ln\,(A^x_{\text{sat}} - A^x(t)) = a - bt \qquad (1)$$

For different values of the saturation amplitude A^x_{sat}, this relation is shown in Fig 2 Here a saturation value of 142 5 per cent gives the best match with the experimental points The rate constant b is exponentially related to the cavity temperature T

$$b = b_0 . \exp\left(-\frac{\Delta E}{2kT}\right) \qquad (2)$$

Fig 3, upper part, shows the relation $b(1/T)$ From this the activation energy was shown to be ΔE = 0 64 eV After equation (1) with A^x_{sat} = constant, the rate constant can also be calculated from the reaction rate dA/dt at the time t (Figs 2 and 3) at which the sample was inserted into the heated cavity The activation energy here was ΔE = 0 65 eV , which agrees fairly well with the values stated However, the accuracy of measurement, confined by the small temperature interval investigated, does not allow for exclusion of bimolecular parts of the reaction The observed increase of intensity with time in this intensity could only be found with fresh feather quills, which were sufficiently dried Both influences will be discussed in further investigations

From the constancy of the line-shape parameter A^x/B^x (Fig 2) during the time of measurement, we conclude that there is a slow increase in the concentration of a certain radical Possibly the radical state remains in a fixed position, while the reaction-rate b is determined by solid-state diffusion of gas molecules or lattice defects More probably (cf ref 11), however, it seems that there is a radical state migration to the cystine part of the keratin From experiments in a high vacuum we hope to obtain further information The magnitude of the effect (+30 – 50 per cent) does not explain the absence of the spectra of other amino-acid residues in the keratin In addition, the observed value of ΔE does not correspond to the forbidden gap, which has been calculated for the energy-band model of the protein for a special structure[14] and expanded to other structures[15] Since it was possible to measure dependence on temperature of a transfer process at room temperature we conclude that this radiation reaction is to be defined as indirect Possibly similar indirect actions of radiation may also occur in other dry systems

Structure of *T*-2 Bacteriophage

X-RAY scattering from orientated phages[1,2] togethei with optical measurements[3,4] have shown that the primary orientation of deoxyribonucleic acid (DNA) in the bacteriophage *T*-2 is parallel to the main axis of the phage These data, combined with electron microscopy by Rubenstein[5], and low-energy electron inactivation investigations by Cole[6], enable the construction of a detailed model for the arrangement of DNA in phage head

The model is based on the following experimental observations

(*a*) Cairns[7] reported that the DNA of *T*–2 is 520,000 Å long, as measured by autoradiography Thomas and Berns[8] obtained a value of 550,000 Å by independent methods

(*b*) From the *T*-2 head, Rubenstein[5] extracted DNA with most of its organization still preserved Electron microscopy of this DNA showed a 'bulge' with approximately 80 Å cross-striations The bulge in the DNA was partially uncoiled as a 75 ± 6 Å filament The end of the uncoiled filament showed a stepwise decreasing diameter (Table 1, col 1) The uncoiling of the bulge was from two ends, one from the surface of the bulge, the other from the centre of the bulge The second one corresponded to the end of the bulge located at the tail side of the phage head

(*c*) Slow electron inactivation studies of *T*-2 by Cole[6] showed a central insensitive region in the phage head This is interpreted as representing a DNA free region or a hole

Table 1 COMPARISON OF *T*-2 DNA FILAMENT DIAMETERS

Measured diameters (ref 5) (Å)	Calculated diameter of secondary helix	*n*
27 ± 5	22 7	(DNA molecule)
41 ± 6	44 3	2
57 ± 7	55 1 65 9	3 4
75 ± 6	76 7	5

(*d*) Flow birefringence studies of *T*-2 and *T*-4 bacteriophages by Gellert[4,9] led him to conclude that, for optical effects, about 9–16 per cent of DNA is preferentially aligned parallel to the main axis of the phage Ultra-violet dichroism confirmed the birefringence results[4]

(*e*) X-ray scattering[1,2] of *T*-2 showed preferential alignment of DNA along the main axis of the phage

Model of DNA arrangement in the head of T-2 bacteriophage Combining the foregoing information, we have arrived at the following model The DNA molecule, of length 520,000 Å (ref 7) and diameter 22 7 Å (ref 10), is coiled into a secondary helix This is done in such a way that each turn of the secondary helix will be a multiple of the 34 Å repeat unit of DNA Such coiling allows interdigitation of neighbouring loops and permits the greatest stability The secondary helix will then have a pitch of 20 Å To fit the 80 Å striations observed by Rubenstein[5], a secondary helix loop will consist of five 34 Å repeat units This will give an outer diameter of 76 7 Å for the secondary helix which is 61,000 Å long (Fig 1)

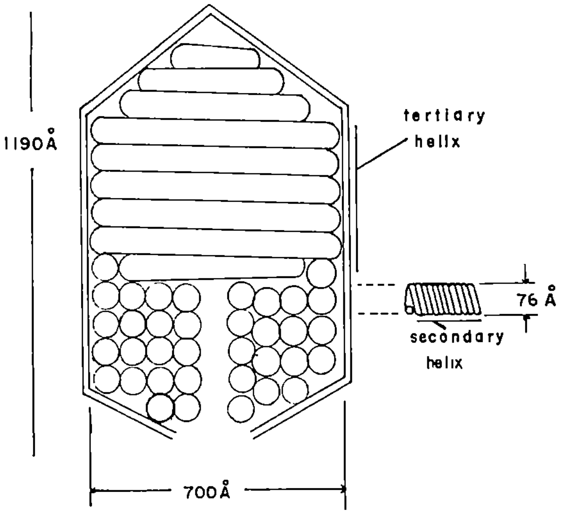

Fig 1

As the next step, the secondary helix is wound into a 'tertiary' helix in the fashion that wire is wound up on a spool Four layers of such tertiary helix are arranged in the phage head (Fig 1) The pitch of the tertiary helix is 76 7 Å , which is equal to the diameter of the secondary helix A phage head, 1190 Å long and 700 Å wide[11], could accommodate a secondary helix 60,000 Å long There would then be an 80 Å. hole in the centre, in agreement with slow electron inactivation studies

The secondary helix ridges on the surface of the final coiling will give the striations on the DNA bulge as observed by Rubenstein[5] The stepwise decreasing diameter of the uncoiled filament is explained by the stretching of the secondary helix so that the helix will have a smaller number (*n*) of DNA repeat units of 34 Å per individual loop (see Table 1 for comparison) Such organization of the DNA would presumably be formed in a fashion as proposed by Kellenberger and

Sechaud[12], according to their 'condensation principle' They showed experimentally that the phage DNA was organized in the infected cell before the assembly of the protein coat[12,13]

Some consequences of the model (1) This arrangement of DNA will give an X-ray diagram with the preferential DNA pattern along the main axis of the phage[1,2]

(2) Detailed calculations of the optical birefringence[14] of the proposed model agree with the quantitative measurements[4]

(3) This model has the additional advantage that the DNA molecule can be easily uncoiled starting with the innermost layer at the tail entrance The only motion required is that the segment already unravelled would be free to rotate around its own axis This requirement is needed since, as the molecule unwinds from the centre of the innermost tertiary helix, two rotations are to be performed (*a*) a 360° turn for the uncoiling of each loop of the secondary helix, (*b*) a 360° turn for each loop of the tertiary helix The hole in the tail of the phage is adequate to accommodate the passage of the 22 7 Å diameter DNA molecule

The most reliable data at present available were used to construct the model, but the exact dimensions must still be considered as approximate

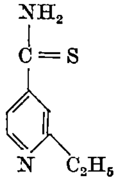
BIOCHEMISTRY

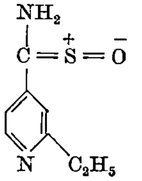
Identification of a Metabolite of the Antituberculous Drug Ethionamide

Ethionamide (2-ethyl-4-thiocarbamoylpyridine) (I) is a drug which has been introduced recently for the treatment of tuberculosis and which is undergoing widespread clinical trials

The polarographic method for the determination of concentrations of ethionamide in biological fluids is the simplest and most sensitive method available[1] It was noted that, in both human and rabbit serum, in addition to the ethionamide wave, a further polarographic wave was obtained, the half-wave potential of which was about 200 mV more positive than that of ethionamide This wave was ascribed to a metabolite of unknown nature Recently, a sample of the compound (II)[2]



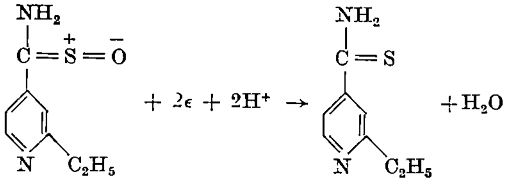
(I)



(II)

hereinafter referred to as ethionamide sulphoxide, was made available to us under the reference 1405*Th* by the Société Theraplix, Paris Its polarographic properties were investigated both in aqueous solution and in normal horse serum These properties, with those of ethionamide in the same media for comparison, are given in Table 1

Ethionamide sulphoxide gave two waves with a separation of half-wave potentials of about 200 mV , and with wave-heights in the ratio 1 2 The half-wave potential of the second wave of ethionamide sulphoxide was so close to that of the single wave of ethionamide that, when both were present in solution, these waves coalesced At equimolar concentrations the heights of the ethionamide wave and the second ethionamide sulphoxide wave were very similar Since it is known that the ethionamide wave is a 4-electron/molecule reduction[3], it follows that the sulphoxide is yielding 2- and 4-electron/molecule waves It seems likely that the first sulphoxide wave is attributable to the reaction



Although the half-wave potential of the first wave of the sulphoxide was very similar to that of the unknown metabolite, this fact by itself was not considered a positive identification It was felt, however, that, if the metabolite could be separated from ethionamide, a positive identification from polarographic properties of the two waves could be made

Partition coefficients of the two compounds between horse serum and ether measured by a polarographic method gave these results

Ethionamide K (ether/serum) = 2 7

Ethionamide sulphoxide K (ether/serum) = 0 093, and from these measured values it was calculated that if a sample of serum containing both substances were extracted four times with an equal volume of ether, the concentrations left in the serum would be

Table 1 Polarographic Properties of Ethionamide and Ethionamide Sulphoxide

Medium	Compound	Concentration	Wave-heights (μamp)			Half-wave potentials (V vs S C E)		
			Wave (1)	Wave (2)	Ratio	Wave (1)	Wave (2)	ΔE
*p*H 9 buffer	Ethionamide	0 40 m*M*	—	6 8	—	—	0 99	—
*p*H 9 buffer	Ethionamide sulphoxide	0 40 m*M*	3 0	5 9	2 0	0 74	0 99	0 25
*p*H 9 buffer	Both	0 40 m*M*	3 1	12 7	—	0 76	1 00	0 24
Horse serum	Ethionamide	0 04 m*M* = 6 6 μgm /ml	—	0 45	—	—	0 94	—
Horse serum	Ethionamide sulphoxide	0 04 m*M* = 7 2 μgm /ml	0 20	0 46	2 3	0 71	0 92	0 21
Horse serum	Both	0 04 m*M*	0 20	0 86	—	0 72	0 92	0 20

0 5 per cent for ethionamide and 70 per cent for ethionamide sulphoxide of the amounts originally present A serum sample taken from a rabbit 90 min after oral administration of 400 mgm /kgm of ethionamide was examined polarographically before and after four-fold ether extraction, the results being as in Table 2.

Table 2 POLAROGRAPHIC PROPERTIES OF A SAMPLE OF RABBIT SERUM TAKEN 90 MIN AFTER ORAL ADMINISTRATION OF 400 MGM /KGM ETHIONAMIDE

Sample	Wave-heights (μamp)			Difference of half-wave potentials (V)*
	Wave (1)	Wave (2)	Ratio	
Before ether extraction	0 97	7 3	—	0 21
After 4-fold ether extraction	0 65	1 6	2 5	0 17

* Owing to the small volume of serum the polarograms had to be recorded against a silver wire internal anode In these circumstances, absolute values of half-wave potential are not significant although the differences are significant

It is obvious from Table 2 that the polarographic properties of the metabolite, after 99 5 per cent of the ethionamide had been separated, are virtually identical with those of ethionamide sulphoxide in horse serum, slight differences being attributable to pH differences or the presence of dissolved ether It is also noteworthy that from the values of the height of wave (1) before and after extraction, 67 per cent of the metabolite was left in the serum after extraction, compared with 70 per cent required for ethionamide sulphoxide

This treble characterization of the metabolite, namely, ratio of wave-heights, difference of half-wave potentials and partition coefficient, makes its identification as ethionamide sulphoxide certain

The fact that this metabolite gives a polarographic wave having a half-wave potential identical with that of ethionamide means that concentrations of ethionamide in serum and cerebrospinal fluid as measured by the polarographic method will be incorrectly high whenever this metabolite is present[4] The extent of the error can be calculated from the known polarographic properties of the metabolite On results published to date, this error has not exceeded 50 per cent of the reported 'ethionamide' concentrations

Inactivation of Staphylococcal Penicillinase by Reaction with Resistant Penicillins

WHILE studying the kinetics of penicillinase inactivation of various penicillins, it became evident that a penicillinase-susceptible penicillin, such as benzylpenicillin, behaved differently from resistant penicillins, such as methicillin (2,6-dimethoxyphenyl penicillin) or oxacillin (5-methyl-3-phenyl-4-isoxazolyl penicillin) (The trade name of Bristol Laboratories, Division of Bristol Myers Co , for methicillin is 'Staphcillin' and for oxacillin is 'Prostaphlin') The former was decomposed at a constant rate for the greater part of the reaction while the rate of decomposition of the resistant penicillins progressively decreased and only a small fraction of the penicillin was finally destroyed under the conditions of this experiment

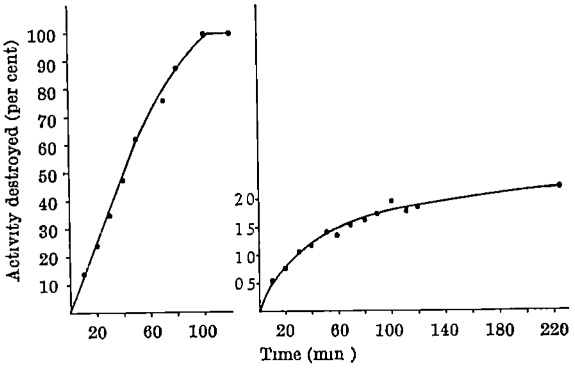

Fig 1 Destruction of different penicillins by staphylococcal penicillinase. 0 06 M penicillin was reacted with 100 μgm /ml. staphylococcal penicillinase in 0 25 M phosphate buffer at pH 6 5 Left, Benzylpenicillin, right, methicillin Note different scales for percentage of destruction

This phenomenon was investigated using Tucker's iodometric method[1] to determine penicillin decomposition The staphylococcal penicillinase used in this work was prepared using the method of Gilson and Parker[2] and methicillin-induced *Staphylococcus aureus* cells (M-2 strain, kindly supplied by Dr Steinman) Fig 1 illustrates the different pattern of behaviour of benzylpenicillin and methicillin already described

It was at first thought that the results may be explained by inhibition of the reaction by the reaction products This hypothesis was tested by degrading methicillin with penicillinase, extracting the penicilloic acid thus formed and adding it to the reaction mixture No effect was observed The penicilloic acid of methicillin did not influence the degradation

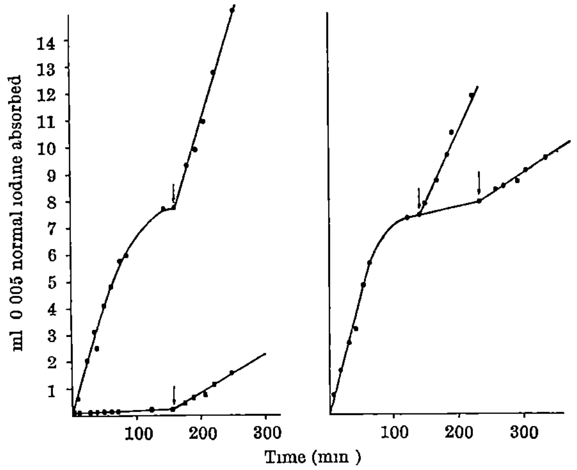

Fig 2 Effect of different penicillins on penicillinase Left, 0 06 M solution of benzylpenicillin or methicillin were incubated with 100 μgm /ml staphylococcal penicillinase The amount of decomposition was measured by iodometric titration At the times indicated by the arrows, the reaction mixtures were diluted ten-fold with 0 01 M solution of benzylpenicillin, and the incubation and titration continued The amount of iodine absorbed is reported per ml of final solution ●, Benzylpenicillin, ■, methicillin Right, a mixture of 0 06 M benzylpenicillin and 0 06 M methicillin was incubated with 100 μgm /ml. staphylococcal penicillinase, and the decomposition followed by iodometric titration At times indicated by the arrows, aliquot portions were diluted ten-fold with 0 01 M benzylpenicillin and incubation and titration continued Note that (a) the decomposition of the mixture followed benzylpenicillin pattern until complete destruction of this compound, then it followed the methicillin pattern, (b) the reaction with benzylpenicillin (until the first arrow) did not appreciably affect the enzyme, (c) the reaction of penicillinase with methicillin (after destruction of benzylpenicillin—between the two arrows) inactivated the enzyme in a manner similar to the experiment with methicillin alone

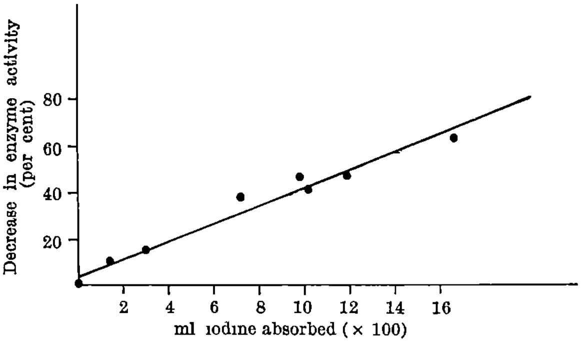

Fig 3 Relationship between penicillinase activity and the amount of methicillin destroyed

of either benzylpenicillin or methicillin when added at the same molarity as the penicillins (0 01 *M*)

Another possibility that could account for the effect is that the enzyme is inactivated in the course of reaction with the resistant substrates This hypothesis was tested in the following way

Equivalent amounts of benzylpenicillin and methicillin and also a mixture of the two were treated with equal amounts of staphylococcal penicillinase The course of the reaction was followed by iodometric titration After some time, the reaction mixtures were diluted 1 10 with a solution of benzylpenicillin in 0 25 *M* phosphate buffer *p*H 6 5 and the course of the reaction again followed iodometrically As benzylpenicillin is 200 times more susceptible to decomposition than methicillin[3], the rate at which it decomposes after being added to the reaction mixture is indicative of the amount of non-inactivated enzyme

The results of this experiment are indicated in Fig 2 It is apparent from this figure that the decomposition of benzylpenicillin does not affect the enzyme since the decomposition of the second portion of benzylpenicillin proceeds at essentially the same rate as that of the first In contrast to this, contact of the enzyme with methicillin markedly reduces the activity of the enzyme That these effects are not due to a competitive inhibition of the enzyme is shown by the behaviour of the mixtures of the substrates The benzylpenicillin component is decomposed at the same rate as if it were the only penicillin present, and its decomposition does not change the activity of the enzyme When all benzylpenicillin is degraded, the methicillin begins to affect the enzyme and the reaction-rate decreases Similar results were obtained when oxacillin was used in place of methicillin

In order to determine whether the degree of enzyme inactivation is a direct function of the amount of the resistant penicillin destroyed, the following experiment was conducted methicillin was incubated with penicillinase under the same conditions as in previous experiments, and at various times samples were taken to determine the amount of methicillin decomposed and the degree of inactivation of the enzyme The latter was determined by measuring the rate of decomposition of benzylpenicillin In Fig 3 is plotted the decrease of enzyme activity against the amount of methicillin destroyed It will be seen that there is a direct relationship between the two

The experiments thus indicate that the reaction of staphylococcal penicillinase with penicillinase-resistant penicillins, methicillin and oxacillin, leads to an inactivation of the enzyme Thus, these penicillins are biologically active not only because of their resistance to hydrolysis by the penicillinase, but also by virtue of their ability to inactivate the enzyme that would ordinarily destroy them

After this work was completed, it came to our attention that Crompton *et al* [4] had made similar observations However, they did not provide any experimental details

Effect of Dilution on the Lactic Dehydrogenase Isozyme Pattern obtained in the Starch Gel

The demonstration of the heterogeneity of lactic dehydrogenase (LDH) activity in human serum and red cells[1] was followed shortly by a report describing LDH heterogeneity in tissues of other mammals[2] Multiple molecular forms of LDH have been utilized in clinical medicine[1,3–5], embryology[6] and tissue culture[7] Markert and Møller directed attention to the general phenomenon of multiple enzymatic forms exhibiting similar substrate specificities within a cell by designating them isozymes[6] Recent reports have indicated that tissue homogenization[8] and enzyme purification[9] may alter the pattern of isozymes observed in the starch gel The present communication shows that the LDH isozyme pattern obtained may be altered by changing the concentration of enzyme activity applied to a starch gel prior to electrophoretic separation The distribution of total LDH activity among the 5 LDH isozymes of human leucocytes and muscular tissue varies according to the amount of activity applied (Fig 1) Since relative activities of the serum LDH isozymes have been used in the diagnosis of disease states[1,3–5], it is important to specify the total amount of activity applied prior to electrophoresis

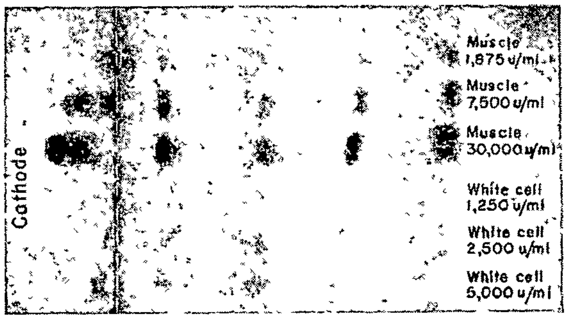

Fig 1 Photograph of a starch gel in phosphate–citric acid buffer *p*H 7 0, 0 01 *M*, stained histochemically for LDH activity (ref 5) Human leucocytes and muscle prepared as previously described (ref 5) were diluted prior to application to produce the units of LDH activity indicated Note that with increasing dilutions isozyme 5, the cathodally migrating band, changes electrophoretic mobility and disappears, whereas the anodally migrating isozymes are visualized at all dilutions Note also that the intensity of staining of the anodal bands decreases approximately in proportion to the dilution in LDH units of leucocyte and muscle extract

Human liver and muscle obtained at autopsy and leucocytes prepared by dextran sedimentation were disrupted by sonic oscillation, centrifuged, the supernatants assayed spectrophotometrically for LDH activity[5] and then applied in varying dilutions to starch gels prepared as previously described[5] in a phosphate–citric acid buffer *p*H 7·0, 0·01 *M*. After vertical starch-gel electrophoresis for 12 hr. the gels were sliced and stained histochemically for LDH activity[5]. The results show that isozyme 5, the cathodally migrating band, present in human liver, muscle and leucocytes, is intensely stained only at high total LDH activities (Fig. 1) and that at lower activities isozyme 5 may not be observed although the anodally migrating isozymes are visualized (Fig. 1). The dilutions were made with distilled water or with phosphate-citric acid buffer *p*H 7·0, 0·01 *M*. With increasing dilutions the mobility of isozyme 5 is regularly altered until it fails to migrate into the gel and probably remains at the origin as suggested by the increased staining observed at the origin in very dilute samples. Differential loss of LDH activity in isozyme 5 with dilution also occurred in borate starch gels at *p*H 8·9, 0·01 *M* or at *p*H 9·5, 0·01 *M*, but was not observed when either filter paper in barbital buffer *p*H 9·5, 0·053 *M* or a starch block in barbital buffer *p*H 8·6, $\mu = 0·01$ was used. With filter paper or starch as a supporting medium all LDH isozymes behaved identically on dilution. Therefore, the phenomenon in the starch gel of differential loss of activity in LDH isozyme 5 on dilution appears to be artefactual. Since the starch gel has been utilized by certain workers for diagnostic purposes[4], it should be emphasized that material low in LDH activity may be unsuitable for application to the gel because isozyme 5, frequently not observed or observed only in trace amounts at low total activities, may become very prominent at higher total activities.

Appearance of Fructose-1,6-Diphosphatase in Post-Natal Rat Liver

MANY liver enzymes are known to increase in activity after the birth of mammals[1–4], but the biological significance of such changes is often difficult to assess. Mitochondrial enzymes concerned with the metabolism of carbohydrate[4] and microsomal enzymes[1,2] show especially marked changes in the liver of early post-natal animals. In the rat, sheep, pig and guinea pig, glucose-6-phosphatase a microsomal enzyme, makes its first appearance at parturition[1]. This enzyme is an obligatory component of the system for the conversion of liver glycogen to blood glucose, and its rapid appearance at parturition reflects the changed circumstances of the new-born, in that the animal is now obliged to regulate its own blood glucose-levels.

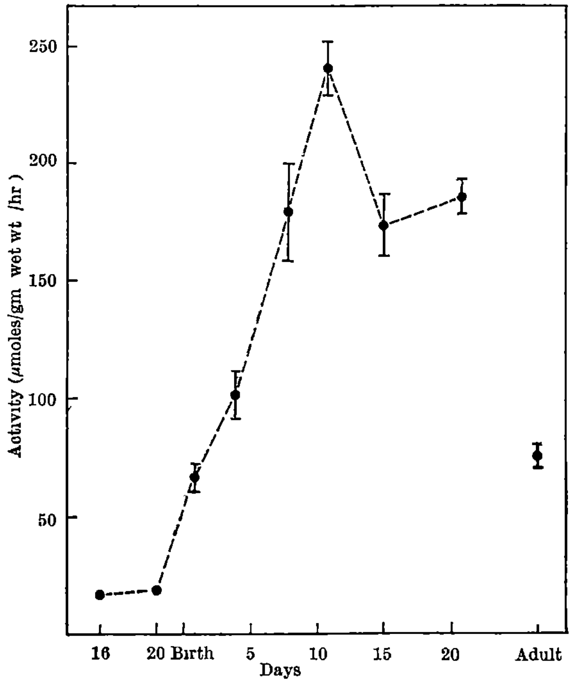

Fig. 1. Appearance of fructose-1,6-diphosphatase in post-natal rat liver. Enzyme determinations in liver homogenates by the method of Pogell and McGilvery. Temperature of assays, 30°. Each point represents the mean of determinations on 4–7 animals. The vertical bars represent ± 1 *S.E.*

This communication describes the appearance of fructose-1,6-diphosphatase in the post-natal rat liver and the changes which occur in its activity during subsequent growth of the animal.

Young of the Wistar albino strain of *Rattus norwegicus* were killed by decapitation. The livers were removed and homogenized in borate buffer *p*H 9·3 in chilled coaxial homogenizers. Fructose-1,6-diphosphatase was assayed in these homogenates at 30° C. by the method of Pogell and McGilvery[5]. Pregnant rats were killed by a blow on the head. The embryos were removed immediately and the livers treated in the same way as the post-natal livers. The stage of pregnancy was determined by the time after the appearance of a vaginal plug.

The activity of fructose-1,6-diphosphatase throughout the period studied is shown in Fig. 1. The assay method also detects non-specific alkaline phosphatase, and although the activity of this enzyme is low compared with fructose-1,6-diphosphatase in the adult rat liver[6], it is a characteristic enzyme of embryonic liver[7]. The apparent activity of fructose-1,6-diphosphatase present in the fœtal liver may therefore be due to alkaline phosphatase, but with present assay procedures the activities of these two enzymes cannot be distinguished in homogenates. Notwithstanding this fact, the rate of hydrolysis of fructose-1,6-diphosphatase by the liver increases sixteen-fold during the first 11 days after birth, and it should be noted that during this period glycogen is resynthesized in the post-natal liver[8]. Fructose-1,6-diphosphatase is an obligatory enzyme in the synthesis of glycogen from glycerol, lactate or amino-acids, and the liver of the rat thus acquires this ability only near the time of birth of the animal. On this evidence it is suggested that the large glycogen deposits formed in the fœtal liver prior to parturition[8] are synthesized from hexose units obtained from the maternal circulation. This contention is further supported by a report that hexokinase, which is required for hexose phosphorylation, has a high activity in fœtal livers[9]. In the embryonic chicken liver, on the other hand, a very high activity of fructose-1,6-diphosphatase occurs as early as 10 days[10,11] and this organ is thus capable of the synthesis of glycogen from varied metabolic sources during the later embryonic development of the animal.

Effects of Insulin on Turnover of Carbon-14 in HeLa Cells

AN *in vitro* assay which could be adapted to a routine determination of some physiological effect of insulin would be useful in a search for new compounds having insulin-like activity. These preliminary investigations were designed to determine whether insulin would influence the turnover of carbon-14 labelled HeLa cells.

HeLa cells were labelled with carbon-14 by growing them in tubes in Eagle's medium containing L-methionine-methyl-^{14}C (6.55 μc./μmole). The glass-attached labelled cells were washed with 'Lactalplus' medium[1] containing 10 per cent (v/v) calf serum, incubated for 4–6 hr. in a fresh portion of this medium, rewashed with medium and finally incubated at 37° in fresh medium with and without insulin (1 I.U. per ml.). (A clinical preparation (Iletin^R, Lilly) was used in these experiments. The results have since been confirmed with crystalline insulin (California Corporation for Biochemical Research).)

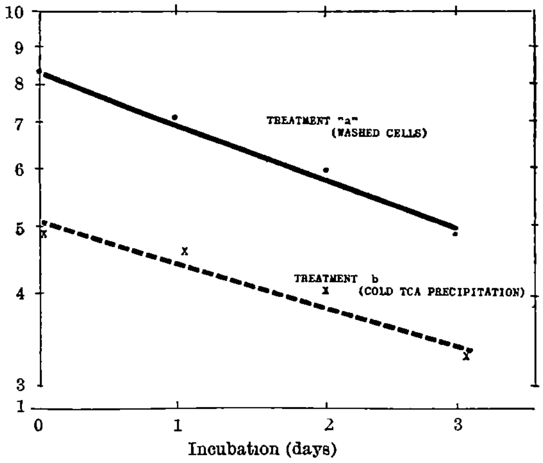

Fig. 1. Turnover of carbon-14 labelled HeLa cells

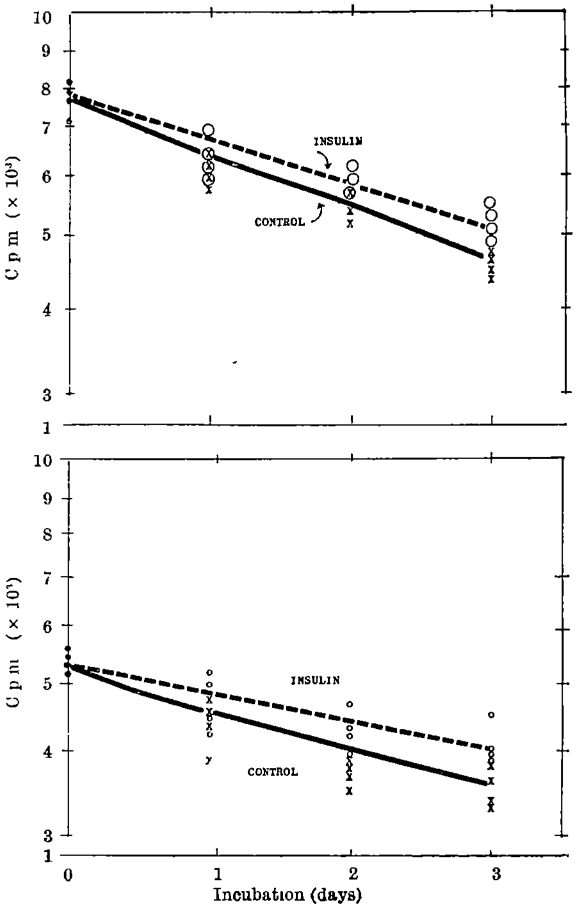

Fig. 2. Effect of insulin on the turnover of carbon-14 in labelled HeLa cells. *a* (above), treatment *a* (washed cells); *b* (below), treatment *b* (cold trichloroacetic acid precipitation)

At various time intervals the cells were washed with warm balanced salt solution and then treated as follows: (*a*) no treatment; (*b*) treated with 5 per cent cold trichloroacetic acid and then extracted with ethanol and ether. Cells were prepared for counting by dissolving them in a solution of 2 per cent Difco '1: 250' trypsin in 0.2 per cent sodium carbonate. Aliquots of the dissolved cells were dried in nickel-plated planchets and counted for a total of 6,400 events. Corrections were made for self-absorption. As measured by treatment (*a*) approximately 50 per cent of the added label was incorporated into the cells.

In Fig. 1 the turnover of carbon-14 can be seen to occur linearly over the three-day period. From the slope of these curves a turnover-rate of about 0.65 per cent per hour was calculated. This value is somewhat lower than the 1 per cent per hour reported by Eagle[2] for HeLa cells, and is slightly higher than that reported by Jordan *et al.*[3] for Walker 256 carcinoma.

A lower rate of turnover was observed for cells treated with insulin (Fig. 2*a* and *b*). In order to assess the consistency of these results, experiments were carried out and the data were treated statistically. Decay curves were plotted by the method of least squares and were found to correspond to the following equations:

Insulin added, treatment (*a*) $y = 3.88 - 0.041x$
Insulin added, treatment (*b*) $y = 3.71 - 0.041x$
Control treatment (*a*) $y = 3.88 - 0.074x$
Control treatment (*b*) $y = 3.71 - 0.060x$

With both treatments the difference in slopes between insulin-treated and control cultures was significant at the level of 5 per cent, showing that insulin retarded the rate of turnover of carbon-14

We thank Dr. W Kwolek for his help in the statistical treatment of the data

Effect of 6-Mercaptopurine on Carbohydrate Metabolism of Human Cancer Cells

In an investigation directed toward the evaluation of the relative effects of various chemotherapeutic chemicals or drugs on the carbohydrate metabolism of intact human cancer cells[1], an unpredicted and unusual disappearance of glucose was noted when cells were incubated with 6-mercaptopurine This effect was discernible under a variety of test conditions, incubation time varied from 1 to 3 hr , cell concentrations varied from 60 × 10^6 to 230 × 10^6, chemical concentration varied from 5 to 50 μgm /10^6 cells It was also discernible in all human cell types investigated, acute and chronic lymphatic leukæmia, acute and chronic myelogenous leukæmia, and in ascites cells from patients with carcinoma of the ovaries It is also readily demonstrated with tumour cell suspension obtained from a transplantable (in Sprague–Dawley rats) chloromyeloid leukæmia[2] In all, this effect has been found without exception in some 30 separate examinations of human cancer cells

In Table 1 are summarized the results of a typical experiment which demonstrates this unusual effect The cells were obtained from a patient with sub-acute lymphatic leukæmia The glucose utilized is the difference between the glucose at zero time and the glucose in the flask at the end of the experiment as determined by the glucose oxidase test[3] The glucose dissimilated is the sum of glucose equivalents used in respiration and glucose equivalents of lactic acid produced, the latter was determined by a chemical method[4] The excess of glucose dissimilated over the control value is due entirely to the stimulation of aerobic lactic acid production by the chemicals, except for nitrogen mustard which produced inhibition of lactic acid production The quantitative effects caused by changes in respiration are almost negligible

Table 1 Balance of Glucose Utilization of Human Leukæmic Leucocytes in Homologous Plasma

Condition	Chemical concentration (μgm /10^6 cells)	Glucose utilized* (mgm)	Glucose dissimilated† (mgm)	Differences (mgm)
Control	0	0 20	0 22	0 02
Diazouracil	22	0 57	0 51	0 06
8-Azaguanine	21 6	0 66	0 75	0 09
6-Mercaptopurine	21 9	*2 56*	0 46	*2 10*
Nitrogen mustard	21 8	0 20	0 16	0 04
Triethylene thiophosphoramide	10 9	*1 21*	0 71	*0 50*
Vinleucoblastine	3 3 ,	0 60	0 59	0 01

* Glucose in flask at zero time minus glucose in flask at end of experiment

† Sum of glucose equivalents used in respiration and glucose equivalents of lactic acid produced

The broader aspects of these chemical effects will be published elsewhere[5]

In the last column can be seen the unusual effect produced by 6-mercaptopurine This amount of glucose represents more than 50 per cent of the glucose initially present The effect of triethylene thiophosphoramide is worthy of note However, we have not observed this effect in all our work as we have with the 6-mercaptopurine

It has been reported[6] that 6-mercaptopurine causes an increased deposition of glycogen in the cells of Ehrlich ascites tumour obtained from mice given intraperitoneal injections at 100 mgm /kgm for 4 days followed by intraperitoneal glucose injections This group[7] also report a concomitant inhibition of lactic dehydrogenase, under their experimental conditions

However, under the conditions of our experiments, short term and *in vitro*, lactic dehydrogenase inhibition is not evidenced based on the stimulation of aerobic lactic acid production

It is possible that the immediate effect is on the hexokinase reaction with subsequent disposition of the glucose-6-phosphate dependent on intracellular enzymatic conditions. The quantitative localization of this 'missing' glucose is under investigation in human and animal cancer tissues[8]

Not to be overlooked is the fact that the specific stimulation of glucose uptake by 6-mercaptopurine offers a new approach to the control of diabetics

Effect of Pyridine Nucleotides on the 1-^{14}C-Glucose Utilization of Normal Human Red Blood Cells

A number of investigators have shown that disphosphopyridine nucleotide (DPN) and triphosphopyridine nucleotide (TPN) enhance the metabolism of glucose in liver preparations via the Embden–Meyerhof and pentose-phosphate (hexosemonophosphate) pathways, respectively[1-3] We have found that TPN and reduced triphosphopyridine nucleotide (TPNH) stimulate the 1-^{14}C-glucose metabolism of normal human red blood cells as measured by the increased production of $^{14}CO_2$ with increasing amounts of the pyridine nucleotides Since normal human red blood cells contain an Embden–Meyerhof pathway but cannot oxidize pyruvate, the only source of carbon dioxide is from the decarboxylation of carbon-1 in the pentose-phosphate pathway Therefore, $^{14}CO_2$ production is a measure of the amount of 1-^{14}C-glucose metabolized via the pentose-phosphate pathway

Blood was obtained by venipuncture from normal fasting subjects, placed in a flask containing heparin, the plasma removed by centrifugation at 2,500 r p m for 10 min , and the cells washed three times in Krebs–Ringer-phosphate buffer, *p*H 7 3 The buffy coat and top layer of the packed red blood cells were discarded One-half ml of packed red blood cells weighing 0 5 gm was placed into a 25 ml Erlenmeyer flask equipped with a centre well, containing 2 ml of Krebs–Ringer-phosphate buffer with 22,200 c p m of 1-^{14}C-glucose (0 03 μgm) and incubated for 1 hr at 37° C in an oxygen atmosphere in a metabolic shaker at 45 cycles per min At the end of incubation 1 ml of 1 *M* hyamine base was injected into the centre well and 0 3 ml of 0 4 *N* sulphuric acid was injected into the red cell suspension The flask was incubated for 1 hr to allow for complete trapping of carbon dioxide The hyamine was then transferred to a vial containing 15 ml of scintillation fluid (2,5-diphenyloxazole) and counted in a Packard liquid scintillation counter[4] DPN, reduced DPN (DPNH), TPN, and TPNH (obtained from Sigma Chemical Co , St Louis, Missouri) were added in varying amounts (0 1, 1 0, and 2 0 m*M*) to the appropriate flasks

The typical response of normal human red blood cells to the various pyridine nucleotides is shown in Fig 1 Both TPN and TPNH stimulated the metabolism of 1-^{14}C-glucose as measured by the increased production of $^{14}CO_2$ The greatest increase was seen at levels of 2 0 m*M* DPN and DPNH were only mildly stimulatory

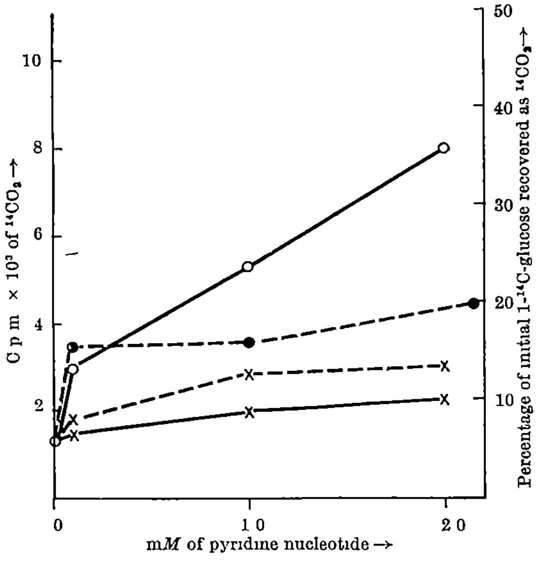

Fig 1 Effect of pyridine nucleotides on the 1-^{14}C-glucose metabolism of human red blood cells Normal human red blood cells, 0 5 gm., added to 2 0 ml of Krebs–Ringer-phosphate buffer, *p*H 7 3, containing 22,200 c p m of 1-^{14}C-glucose, and incubated for 1 hr at 37° C in an oxygen atmosphere There were 100 white blood cells per mm^3 in the red blood cell suspension O, TPN added, ●, TPNH added, x——x, DPN added, x - - - x, DPNH added

By providing the proper coenzyme (TPN) in greatly excess amounts for the enzymes of the pentose-phosphate pathway (glucose-6-phosphate dehydrogenase and 6-phosphogluconic acid dehydrogenase) the glucose is increasingly metabolized via the pentose-phosphate pathway as reflected by an increase in the $^{14}CO_2$ production The TPNH could become stimulatory by being converted to TPN by reacting with DPN in a transhydrogenase reaction[5] as follows

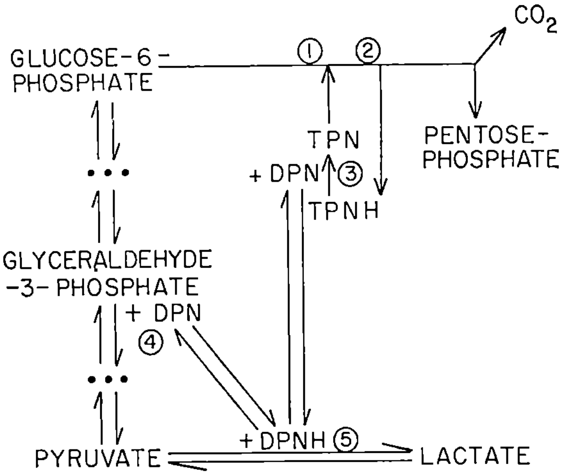

Fig 2 Schematic diagram depicting the interrelationships between TPN, TPNH, DPN and DPNH in the red blood cell The enzymes involved are (1) glucose-6-phosphate dehydrogenase, (2) 6-phosphogluconic acid dehydrogenase, (3) transhydrogenase, (4) glyceraldehyde-3-phosphate dehydrogenase, (5) lactic acid dehydrogenase

$$\mathrm{TPNH+DPN = TPN+DPNH}$$

The DPN is regenerated with the formation of lactate from pyruvate and is available again to react with TPNH

$$\mathrm{DPNH+pyruvate = DPN+lactate}$$

Only slight stimulation occurred with DPN and DPNH alone In each case both could eventually react with endogenous TPNH, but since the amount of endogenous TPNH is necessarily limited only a slight degree of stimulation would be expected Fig 2 depicts the sequence of events in a simplified fashion.

Kinetics of Synthesis of Fibroin in the Posterior Division of the Silk-gland of the Silkworm, *Bombyx mori*, L.

The synthesis of fibroin and secretion in the posterior division of silk-gland can be divided into three phases (1) absorption of amino-acids, (2) synthesis of fibroin, (3) secretion of fibroin We have tried to show that such a complex reaction is an enzyme system, by analysing the phenomenon of the incorporation of glycine labelled with carbon-14 into fibroin *in vitro* A piece of the posterior division of silk-gland, 200 mgm wet weight, 1–2 cm long, was removed from the larva of the silkworm, *Bombyx mori*,

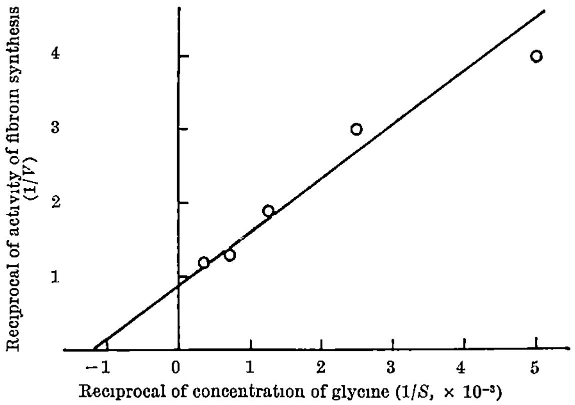

Fig 1 Relation between concentration of glycine (S) and the activity of synthesis of fibroin (V)

during the middle period of the fifth instar, and incubated in a medium consisting of 0 5 ml of saline solution (sodium chloride, 2 0, potassium chloride, 0 2, calcium chloride, 0 08, magnesium chloride, 0 04 per cent), 0 2 ml of 0 2 M phosphate buffer (pH 7 4), 5 μmoles of α-ketoglutaric acid, 210 μgm of glycine, 140 μgm of L-alanine, 75 μgm of L-serine, 70 μgm of L-tyrosine, 0 025 μc of ^{14}C-glycine (4 1 mc /mM) and filled with distilled water to 2 0 ml at 31 7° C, and mildly shaken for 1 hr After the incubation, fibroin in the gland cavity was separated from gland cells by the trichloroacetic acid method[1]

The relation between the concentration of glycine in the medium and the activity of synthesis of fibroin is shown by calculating from the value of ^{14}C-glycine incorporation into fibroin at respective concentration of glycine varying from 30 to 500 μgm / 2 ml (Fig 1) This result showed that the reaction of synthesis of fibroin in the posterior division of silk-gland nearly followed the Michaelis–Menten law, and the Michaelis constant K_{Mg} of the reaction concerning glycine was 6 2 × 10^{-4} M Moreover, it was made clear that the activity of fibroin synthesis varied with the concentrations of tyrosine between 0 and 10 μgm /2 ml, by calculating the value of ^{14}C-glycine incorporation into fibroin with co-existence of tyrosine at above concentrations In this case, the reaction nearly followed the Michaelis–Menten law as the case of glycine and the Michaelis constant K_{Mt}, so far as tyrosine was concerned, was 1 4 × 10^{-5} M

The ratio of the Michaelis constant of glycine-enzyme complex to that of tyrosine-enzyme complex in the reaction of fibroin synthesis may be 7 5 1, representing the constructive molar ratio of these two amino-acids in fibroin[2] However, the ratio of K_{Mg} to K_{Mt} presented from the foregoing experiments was 44 3 1, which did not agree with the expected ratio Therefore, K_{Mg} and K_{Mt} seem to be apparent values It was assumed that the true concentration of the substrate, such as glycine or tyrosine, for the reaction of fibroin synthesis was the sum of the concentration of the substrate which was added to the reaction mixture before the incubation and that of the substrate which existed in the gland cells The concentrations of the substrates existing in the gland cells were calculated as 7 0 × 10^{-5} M of glycine and 1 2 × 10^{-5} M of tyrosine, by comparison of the rate of ^{14}C-glycine incorporation into fibroin after pre-incubation under the condition of glycine-deficiency and presence of glycine The actual Michaelis constants concerning glycine and tyrosine were 1 0 × 10^{-3} and 1 3 × 10^{-4} M, respectively

Table 1 EFFECT OF CO-EXISTENCE OF ALANINE, SERINE AND TYROSINE ON THE INCORPORATION OF ^{14}C-GLYCINE INTO FIBROIN OF THE POSTERIOR DIVISION OF SILK-GLAND *in vitro*

Amino-acids present	Relative activity Exp 1	Exp 2	Exp 3	Average
Glycine	100*	100*	100*	100
Glycine + alanine	106	113	—	110
Glycine + alanine + serine	64	61	—	63
Glycine + alanine + serine + tyrosine	316	437	—	377
Glycine + tyrosine	—	301	300	301
Glycine + alanine + tyrosine	—	516	326	421

* Activities were 441 in experiment 1, 88 in experiment 2 and 63 c p m /mgm fibroin in experiment 3

The effects of the co-existence of amino-acids other than glycine on the incorporation of ^{14}C-glycine into fibroin were as follows alanine did not show any remarkable effect, serine retarded the reaction but tyrosine was apparently effective in acceleration (Table 1) Such an effect of tyrosine emerged from the fact that this amino-acid was essential for the reaction of the composition of the amino-acids in fibroin, since there were no effects of the related compounds of tyrosine, that is, phenylalanine, tyramine, phenol, p-cresol, DL-fluorophenylalanine and tryptophan, on the reaction of incorporation of ^{14}C-glycine into fibroin Moreover, it was shown that glycyl-tyrosine accelerated the incorporation of ^{14}C-glycine into fibroin through decomposition of the peptide by dipeptidase in the gland cells, while glycylglycine showed no effect on the reaction

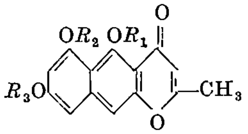
Fonsecin, a Naphthopyrone Pigment from a Mutant of *Aspergillus fonsecaeus*

IN 1953 Raper and Fennell[1] described an ultraviolet mutant of *Aspergillus fonsecaeus* (N R R L 67), which was characterized by a rich deposit of yellow pigment in the vesicles and primary sterigmata We became interested in this material as a possible precursor of the brown and black pigments of the parent strain and, accordingly, isolated the crude pigment by ethyl acetate extraction of the dried mycelial mat Fractional precipitation and recrystallization from ethyl acetate–petroleum ether mixtures gave a pure substance in the form of bright yellow irregular prisms (m p 198° decomposition) to which the name fonsecin was assigned λ_{max} (ethanol) 233, 275, 321, 332, and 400 mμ (ε, 26,400, 31,400, 7,300, 8,025, and 8,775, respectively) (Found C, 62 3, 62 1, H, 4 94, 4 79, OCH_3, 11 4, CH_3, 6 2 $C_{15}H_{12}O_5$ - H_2O requires C, 62 06, H, 4 82, 1 OCH_3, 10 7, 1 CH_3, 5 2)

Fonsecin is isomeric with rubrofusarin, a red pigment first isolated by Ashley, Hobbs and Raistrick[2] from *Fusarium culmorum* and *Fusarium graminearum* Like these investigators, as well as Mull and Nord[3], we first concluded on the basis of general properties that fonsecin was a dihydroxymethoxy-methylxanthone; recently, however, Dreyer[4], Stout, Dreyer and Jensen[5], and Tanaka and Tamura[6] have established that rubrofusarin is a naphtho-γ-pyrone and is represented by structure I Using this new work as a guide, we have been able to show that fonsecin has structure II



I $R_1 = R_2 = H, R_3 = CH_3$
II $R_1 = R_3 = H, R_2 = CH_3$
III $R_1 = R_2 = R_3 = H$
IV $R_1 = H, R_2 = R_3 = CH_3$
V $R_1 = R_3 = CH_3, R_2 = H$
VI $R_1 = R_2 = R_3 = CH_3$

When fonsecin was demethylated with hydriodic acid, nor-rubrofusarin (III) was obtained (analysis, identical ultra-violet and infra-red curves, m p and mixed melting point with authentic nor-rubrofusarin obtained from rubrofusarin from two different sources, supplied by Drs H Raistrick and J H Birkinshaw and by Dr H G Stout)

On methylation with diazomethane for a short time, fonsecin gives a monomethyl ether (IV) of m p 176° Rubrofusarin monomethyl ether (V) is reported[2,4] to have a m p of 203°–204°, which is the same as that reported by Lund, Robertson and Whalley[7] for asperxanthone, a yellow pigment isolated from *Aspergillus niger* A direct comparison of these two compounds apparently has not been made

Prolonged treatment of fonsecin with diazomethane gives a product (VI) identical in all respects with dimethyl rubrofusarin

When fonsecin monomethyl ether (IV) was oxidized with potassium permanganate[8], 3,5-dimethoxyphthalic acid was detectable by paper chromatography, this acid could not be found when rubrofusarin monomethyl ether (V) was oxidized under the same conditions These findings confirm previous observations[4]

Our yields of fonsecin (4 5 per cent of the dried mycelium) are much higher than those reported by Ashley *et al* [2] for rubrofusarin and by Lund *et al* [7] for asperxanthone Our work makes these natural naphtho-γ-pyrones more readily available now for study

Amino-acids in Corn-steep

LACTIC acid fermentation during the steeping of corn influences the biological value of corn-steep for penicillin fermentation[1–4] Until now no attention has been paid to the changes in the amino-acid content of corn-steep during lactic acid fermentation after the completion of the steeping process

For the quantitative determination of some amino-acids we have used the method of descending electrophoresis according to Mikeš[5] and Bode's evaluation method[6] The methods of cultivation of the strain of *Penicillium chrysogenum NG* on a rotary shaker and the analytical methods used have been described[4]

The fermented samples were prepared in the following way 20 litres of the oldest steeping liquor were withdrawn into a glass flask from the end of the counter-current steeping battery of a corn starch factory After thorough homogenization, 5 litres were withdrawn from the sample and concentrated *in vacuo* in a glass distillation apparatus to contain about 60 per cent dry matter The rest of the steeping liquor was kept at a temperature of 50° C , where it was subject to spontaneous fermentation At 24-hr intervals samples of the fermenting steeping liquor were collected for concentrating *in vacuo* Samples of concentrated corn-steep prepared in this way on a laboratory scale were tested biologically and analysed chemically

Under our experimental conditions, no substantial changes in the amino-acid content were observed in the course of the supplementary fermentation of corn-steep Noticeable differences in the content of aspartic acid were observed only in those batches where this amino-acid was already present prior to the process of fermentation In some of the batches the content of aspartic acid increased during fermentation (Fig 1), in others the content decreased (Fig 2). In batches where this amino-acid was absent prior to fermentation, aspartic acid did not emerge in the course of fermentation It is evident that the increase or

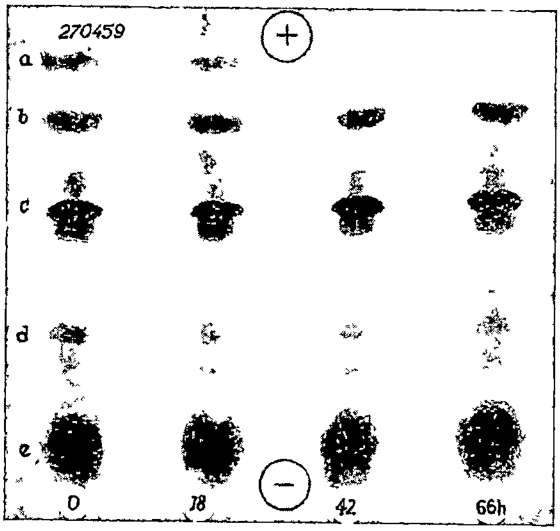

Fig 2 Electrophoretogram of amino-acids of corn-steep *a*, Aspartic acid, *b*, glutamic acid, *c*, neutral amino-acids, *d*, γ-aminobutyric acid, *e*, basic amino-acids

decrease of the content of aspartic acid is caused by a specific microflora

In Table 1 the results of amino-acid assays of some batches of corn-steep and the results of biological tests are presented The yields of penicillin on media prepared with corn-steeps without the supplementary fermentation are considered as 100 per cent The presented results of amino-acid assays are means of results of 15 assays and the biological tests are means of 2–4 assays

The chemical composition of these batches is presented in Table 2 After a 24-hr fermentation the yield of the antibiotic did not decrease in any of the assayed samples, on the contrary, a tendency to increase can be observed From the technological point of view it is important that after a 24-hr fermentation a decrease of foaming of fermented corn-steeps is observed

A Quantitative Cytochemical Technique for Measurement of Glycogen

THERE seems to be a need for a quantitative cytochemical technique for assessment of glycogen within intact cellular structures In histochemical detection of glycogen, only the fraction of total cellular glycogen soluble in trichloroacetic acid takes part in the staining reaction[1] To overcome this difficulty, an attempt has been made to establish the present technique for measuring the absolute dry mass of glycogen of a cell Danielli[2] recorded that after fixation of the tissue in absolute alcohol mainly protein, nucleic acid and carbohydrate remain in the cellular material

A small piece of liver from a normal adult albino rat was quickly fixed in chilled absolute alcohol inside a refrigerator, sectioned at 5μ thickness and mounted on glass slides without application of water and care taken not to overheat in order to prevent the formation of diffusion artefacts, as described before[3] Paraffins were removed from the unstained sections by treatment with xylol, dehydrated in absolute alcohol and some hepatic cells of the same microscopic field of a section were measured in double distilled glycerine before and after digestion in malt diastase solution at 1/1,000,000 under a Baker interference microscope (× 100 objective, numerical aperture 1 30, × 8 binocular eyepieces, mercury green filter) At this higher dilution malt diastase shows only pure glycogenase action[4] without any ribonuclease action Table 1 shows phase difference (in degrees) proportional to dry mass of glycogen per unit area within normal rat hepatic cells

Table 1

Organelles	Average phase difference (300 cells)		Average phase difference proportional to dryness of glycogen per unit area
	Pre-digestion	Post-digestion	
Cytoplasm	44 ± 16	16 ± 4	28
Heterochromatins	41 ± 3	36 ± 4	5
Nucleoli	53 ± 5	49 ± 3	4

The results exhibited in Table 1 show a considerable change in phase difference proportional to dry mass of glycogen per unit area within the hepatic cell cytoplasm of rats Phase changes are insignificant in the nuclei and nucleoli of these cells The present quantitative cytochemical technique, which is quite new, may be utilized also with other tissue fixatives for studying altered cellular functions where glycogen plays an important part This method will also be useful for measuring interferometrically the dry mass of protein in cells where considerable amounts of carbohydrate are present

PHYSIOLOGY

Diffusion Coefficient of Oxyhæmoglobin

In work described elsewhere[1] we showed how to understand the steady-state transport of oxygen through hæmoglobin solution by the application of Fick's law of mass transport The oxygen flux was shown to depend not only on the pressure difference across the diffusion cell but also on the absolute partial pressures of oxygen at the cell boundaries This behaviour is a direct consequence of the non-linear relation between oxyhæmoglobin concentration and oxygen partial pressure We pointed out, for example, that if the hæmoglobin is saturated with oxygen at both ends of the diffusion path it cannot contribute to the transport of oxygen and all the oxygen transport must therefore take place through the plasma

Hemmingsen[2] recently reported a series of experiments which he interprets as showing that although the hæmoglobin is oxygen saturated at both ends of the diffusion path it still contributes to oxygen transport His conclusions are, however, largely incorrect and the experiments prove instead to be an ingenious way of determining the diffusion coefficient for oxyhæmoglobin

Hemmingsen measured the transport of oxygen-18 through a hæmoglobin solution under conditions where the total oxygen pressure was identical at both ends of the diffusion path and maintained large enough to ensure that the hæmoglobin was in the oxygenated form A difference was established, however, in the partial pressures of ^{18}O at the diffusion cell boundaries which caused a transport of ^{18}O across the cell In comparing results for identical experiments with hæmoglobin, methæmoglobin, and water, Hemmingsen found the ^{18}O flux through the hæmoglobin to be about 2 6 times that through methæmoglobin or water

Fick's law is again quite applicable to understanding these experimental results It must be stressed, however, that the law applies only to the ^{18}O, since it is only the flux of this component of the system which has been measured Now although the total pressures of oxygen are maintained equal at each end of the diffusion path, the partial pressures of ^{18}O are not Similarly, though the concentrations of oxyhæmoglobin are the same at each cell boundary, the concentrations of the ^{18}O-hæmoglobin are not equal This is an important point because it is true whether or not all the hæmoglobin is in the oxygenated form In fact a simple equilibrium argument shows that the fractional amount of ^{18}O-oxyhæmoglobin is just equal to the fractional partial pressure of dissolved ^{18}O One can easily picture exactly what must happen in the diffusion cell The concentration gradient of dissolved ^{18}O causes an ^{18}O flux through the plasma while the gradient in ^{18}O-oxyhæmoglobin causes an additional flux of the ^{18}O-oxyhæmoglobin There must also be a flux of ^{16}O-hæmoglobin in the opposite direction to preserve a mass balance on the hæmoglobin We can now use our previous results to write a mathematical expression for the ^{18}O flux

$$J(^{18}O) = \frac{D_A k(P_i - P_f)}{x_f} + \frac{D_E\{f(kP_i) - f(kP_f)\}}{x_f} \qquad (1)$$

where P_i and P_f are the initial and final partial pressures of ^{18}O respectively, k is a Henry's law constant, D_A and D_E are the diffusion coefficient of ^{18}O through plasma and the diffusion coefficient of ^{18}O-oxyhæmoglobin respectively, $f(kP_i)$ is the initial concentration of ^{18}O containing hæmoglobin and $f(kP_f)$ the final concentration, and x_f is the length of the diffusion path

The first term in equation (1) is the oxygen flux through the plasma, the second is an additional flux due to the presence of a gradient in the oxyhæmoglobin concentration In Hemmingsen's experiments on water or methæmoglobin the entire flux is described by the first term of equation (1) In the experiments on hæmoglobin the second term is also important and accounts for the enhanced ^{18}O flux through this solution Using a value of 20–21 vol per cent for the oxygen capacity of the hæmoglobin solution, the data from Fig 2 in ref 2, and applying equation (1), we obtain $1\ 9 \times 10^{-7}$ cm ^{2}/sec for the diffusion coefficient of oxyhæmoglobin, D_E We should point out that one must be very careful in using the numbers in Hemmingsen's Fig 2, since he has not reported the ^{18}O flux but has scaled that flux up by the experimental $^{16}O/^{18}O$ ratio This is a spurious correction and must be removed to obtain the data The previous experiments of Scholander and Hemmingsen[3] wherein the hæmoglobin was oxygen saturated at one end of the path and kept at zero oxygen partial pressure at the other end also give a value of $1\ 9 \times 10^{-7}$ cm ^{2}/sec for D_E This value was chosen by us in our treatment of the steady-state oxygen transport in whole blood[4] and leads to an adequate description of the experimental data on whole blood obtained by Scholander[5]

The ^{18}O experiments might profitably be done as a function of hæmoglobin concentration to determine the concentration dependence of D_E As it stands they merely show once again that Fick's law is applicable to any component of a system providing the equilibrium with the other components is fast compared with diffusion-rates

Effect of an Anæsthetic on the Heart and Respiration of Teleost Fish

The properties of Sandoz '*M.S.* 222' compound, a meta-amino-benzoic acid ethyl ester in the form of a soluble salt, as a general anæsthetic[1,2] have led to its widespread use in studies of fish physiology. The general effects of this, and other anæsthetics on fish, have been examined by McFarland[3], but, in the course of experiments on some aspects of the respiratory and circulatory physiology of teleosts, it became clear that '*M.S.* 222' caused changes of considerable significance not hitherto described.

In these experiments the electrocardiogram, respiratory rate, and respiratory amplitude were recorded in tench (*Tinca tinca*, L.) held in a tank of 1,750 ml. capacity. Handling the fish caused a considerable rise in the heart-rate, often to three times the value found in a fish that had remained inactive and undisturbed in the tank for periods of more than 1 hr. The usual range of heart-rate in an undisturbed tench was found to be 15–30 beats/min. When the heart-rate had reached this resting value, a known concentration of '*M.S.* 222' was passed through the tank for periods up to 90 min. in duration. Six concentrations of the anæsthetic were used, 25–200 mgm./l., and the experiments were carried out on 15 fish weighing 38–144 gm.

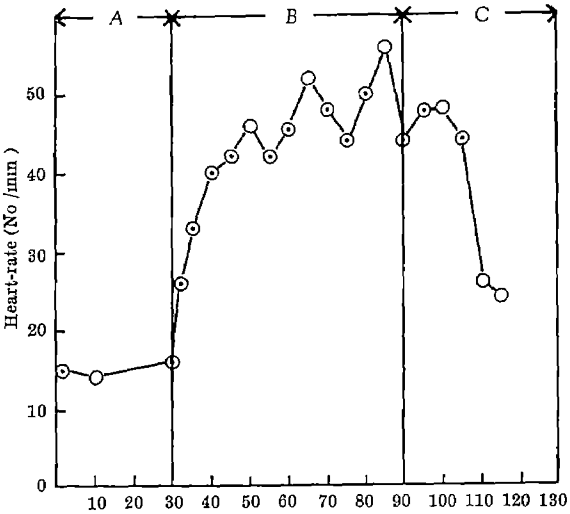

Fig. 1. Effect of '*M.S.* 222' on the heart-rate of a 57-gm. tench (temperature, 17° C.). *A*, Freshwater; *B*, '*M.S.* 222' 33 mgm./l.; *C*, freshwater

The effect of '*M.S.* 222' was to produce an increase in heart-rate (Fig. 1), the increase being more marked at higher concentrations. The respiratory-rate and amplitude were also increased, though in a somewhat variable way as the relationship between these two parameters of the breathing movement is complex. '*M.S.* 222' probably acts on the heart via the parasympathetic nervous system (there being no sympathetic innervation) since the direct effect of the substance on the isolated and perfused hearts of tench, trout and roach was to decrease the frequency of beat. This conclusion was substantiated when it was found that '*M.S.* 222' in the ventilation stream of a tench in which the tenth vagi had been sectioned bilaterally resulted in a decrease in the animal's heart-rate.

The increase in heart-rate caused by '*M.S.* 222' in the intact animal was paralleled by a simultaneous increase in respiratory rate and, though there was no strict correlation between the heart beat and any part of the respiratory cycle, it is suggested that some connexion exists between cardiac and respiratory control systems within the brain. In concentrations of 100–200 mgm./l. '*M.S.* 222' respiratory collapse was common, the breathing becoming irregular and ultimately stopping. Simultaneously the heart-beat would also become irregular and the frequency would fall. Recovery in the breathing was always accompanied by a similar recovery in the regularity and frequency of the heart beat.

Effects of Mammalian Growth Hormone on *Cottus scorpius* Blood

It is now well established that the teleost pituitary contains a growth-promoting hormone, the evidence coming from injection of fish pituitary preparations and from the effects of hypophysectomy[1]. Although growth effects have been studied, the metabolic responses of either fish or mammalian somatotrophin in teleosts, such as possible diabetogenic action, have not been investigated. Both the nitrogen retention and diabetogenic effects of somatotrophin in mammals are well known and it has now been shown during work on hypophysis-pancreas relations in teleost fish that mammalian growth hormone affects blood glucose, protein and urea in *Cottus scorpius*.

Armour 'Somar *A*' was injected intraperitoneally into twelve *Cottus scorpius* weighing 300–500 gm. at a 1 mgm./kgm. dose-level every third day for fifteen days. Blood was obtained from the ductus *Cuvieri* running subcutaneously immediately beneath the operculum and blood sugar determined spectrophotometrically by a glucose oxidase method ('Blutzucker Farb-Test', Biochemica Boehringer). The blood glucose, determined every third day for ten days prior to growth hormone, was 6.6 ± *S.E.* 0.34 mgm./100 ml. blood. There was no rise in blood sugar for the first three days after injection of 'Somar *A*', but within six days the blood glucose-level had risen to 12.6 ± *S.E.* 1.11 mgm./100 ml. This marked elevation of blood glucose was maintained for the duration of the injections. This effect is in contrast to fish growth hormone injections, which exert no metabolic effect in mammals (nitrogen retention, cardiac glycogen)[2] and to experiments which indicate that hypophysectomy of *Cottus scorpius* does not result in any lowering of blood glucose-levels over a period of a month[3].

After fifteen days, blood samples of the growth hormone treated fish were taken and the plasma total protein, urea and amino-acid nitrogen determined by biuret, urease-nesslerization and β-naphthoquinone-4-sulphonate methods respectively. The total plasma protein of the treated fish was lowered, being 24.5 mgm. ± *S.E.* 2.45/ml. compared with an untreated fish value of 34.1 mgm. ± *S.E.* 1.79/ml. The plasma urea was also reduced to 65.8 μgm. ± *S.E.* 5.32/ml. plasma compared with untreated fish of 109.0 μgm. ± *S.E.* 14.5/ml. plasma. The nitrogen retention effect of mammalian growth hormone on fish is thus demonstrated, both results being significant at the 5 per cent levels. The plasma and amino-acid values were not, however, significantly different, individual valuations showing wide variation. A similar wide scatter of the amino-acid values have been found also in this laboratory in the blood and muscle of trout and goldfish.

It has been postulated that fish growth hormone is antigenic towards mammals but that mammalian preparations are not antigenic towards fish[4], and these observations, showing as they do metabolic responses by a fish to mammalian growth hormone, help to support this view.

At the termination of this growth hormone investigation the adenohypophysis was examined using a variety of histochemical methods in order to determine any effect of exogenous growth hormone treatment on specific cells which might then be designated somatotrophs. No effects were observed and thus the identification of the teleost somatotroph remains still unsolved.

HÆMATOLOGY

Serum Globulin Polymorphism in Pellagra

In recent work on the serum iron and total iron-binding capacity of groups of healthy and diseased Africans, we found the total iron-binding capacity of pellagra patients to be approximately 60 per cent of healthy controls[1]. Zone electrophoresis on filter paper in an earlier work[2] did not show that the concentration of the β-globulins in pellagra was any lower than healthy controls and this suggested that there may be a relationship between transferrin polymorphism and incidence of this disease, in view of the findings of Gibbett *et al.*[3] that the faster-migrating transferrins take up more iron.

21 sera from frank pellagra patients attending Harare and Mpilo Central Hospitals were compared with 25 samples drawn from African blood bank donors by the Smithies vertical starch-gel electrophoresis method[4]. $^{59}FeCl_3$ and hæmoglobin were added to the sera and autoradiographs prepared with one half of the gel on Kodak 'No Screen' X-ray film[3]. The other half was stained with *o*-dianisidine-hydrogen peroxide reagent[5] to establish haptoglobin types and finally counter-stained with naphthalene black. This opportunity was taken to establish the haptoglobin types, as no figures were available for Rhodesian Africans.

Table 1. Haptoglobins and Transferrins in Africans suffering from Pellagra compared with Healthy Controls

	No. of samples	Hp^{0-0}		Hp^{1-1}		Hp^{2-1}		Hp^{2-2}		TfCC		TfCD_1	
Pellagra		No.	Per cent	No.	Per cent	No.	Per cent	No.	Per cent	No.	Per cent	No.	Per cent
	21	2	9·5	6	28·6	11	52·4	2	9·5	18	85·7	3	14·3
Control	25	1	4	8	32	13	52	3	12	22	88	3	12

The results obtained are shown in Table 1, and there is no significant difference between the two groups for any of the phenotypes listed. The respective haptoglobin gene frequencies for pellagra and controls sera are as follows: Hp^0 0·095 and 0·04; Hp^1 0·55 and 0·58 and Hp^2 0·36 and 0·38. This suggests that the presence of a slower moving TfD does not predispose an individual to pellagra and the reason for the low serum total iron binding capacity in this condition remains obscure.

The frequency of Hp^2 in the Rhodesian African is much lower than that for a number of different population groups quoted by Harris[6], although higher than that for the West African Fulani[7], who have a very much higher frequency of Hp^0.

I thank Dr. Elizabeth Robson for supplying a reference sample of TfCD_1 serum; Dr. B. J. Baldachin and Mr. N. Gregory of Mpilo Central Hospital; and Dr. M. Gelfand and Mr. A. Seymour of Harare Central Hospital for arranging the blood samples.

Analogies and Differences between Human and Horse Hæmoglobin

In a previous paper[1] I reported two similar and two different histidine-containing peptides isolated from the high-basic fraction of the tryptic hydrolysate of human and horse hæmoglobin. This communication deals with some peptides isolated from the middle basic fractions of the tryptic hydrolysate of human and horse hæmoglobin.

About 1 gm. of the neutral and middle basic group of tryptic digest peptides of human and horse hæmoglobin was fractionated by ion-exchange column chromatography[2]. The individual peptides were obtained from fractions collected after purification of the peptides by high-voltage paper electrophoresis[3] using pyridine–acetate–buffer system *p*H 6·5 and *p*H 3·5 (ref. 4). Each peptide isolated from tryptic hydrolysate of horse hæmoglobin was compared with that isolated from the tryptic digest of human hæmoglobin[2]. Some individual peptides were split by enzymes or partial acid hydrolysis. The peptides Nos. 5, 6 and 7 were partially hydrolysed with 6 *N* hydrochloric acid at 105° for a period of 20–30 min.[5]. The products of partial acid hydrolysis were fractionated by high-voltage paper ionophoresis using pyridine–acetate buffer *p*H 3·5 (ref. 4). Peptide No. 10 was digested with chymotrypsin to yield two fragments. Both fragments were, after ionophoretic separation, degraded by Edman's method of paper strip modification[6]. The estimation of the N-terminal amino-acid of certain peptides was carried out by Fraenkel-Conrat and Harris paper strip technique[6]. For analysis of amino-acids the high-voltage ionophoresis[3] (2·5 per cent formic acid, 4,000 V./cm. for a period of 40 min.[7]) and paper chromatography in the *n*-butanol–acetic acid–water (4 : 1 : 5) as solvent system was used. Peptides summarized here represent those with identical electrophoretic, chromatographic pattern and other similar characteristics as, for example, both terminal amino-acid and amino-acid composition.

By comparison of these results with the recently published total structure, and chains, of human hæmoglobin[8–10] it is possible to indicate these places in the chains of human hæmoglobin, which are identical with those of horse hæmoglobin. It seems that most of the aforementioned peptides are identical in both hæmoglobins (Table 1). The different peptide No. 6 occupies the same place in the chains of horse hæmoglobin as peptide No. 5 in human hæmoglobin[11]. Peptides No. 7 and No. 13 do not occur as a product of tryptic digestion in any chains of human hæmoglobin[8–10].

Table 1

ANATOMY

Tetracyclines in Human Dentine

WITH the development of new techniques during the past few years, much information has been obtained on the nature of the dentinal tubules and the mode of calcification of the matrix[1].

With the observation that tetracycline drugs are incorporated in tissues which are calcifying at the time of its administration[2], another means of studying these phenomena is now available. The tetracycline is bound in the calcifying zone of the dentine and with ultra-violet light fluoresces bright yellow.

In the present investigation, several deciduous teeth from two children who had received numerous large doses of tetracycline drugs during the first few months of life have been studied. The teeth were yellow in colour, with hypoplastic enamel, most of which had worn off the occlusal surfaces, exposing the dentine.

A longitudinal section was cut from one of these teeth and the areas which fluoresced determined macroscopically or under low power. The tooth was then reorientated on the cutting machine and further sections cut to show the dentinal tubules in cross-section[3].

The preparations were examined with transmitted and ultra-violet light and micro-radiographs were prepared; the appearance under these three conditions was examined.

Longitudinal sections viewed with transmitted light appeared normal except that in some areas a greater number of interglobular spaces was seen than is usually observed in such sections. With ultra-violet light, numerous distinct yellow fluorescent bands were seen, running approximately parallel to the dentino-enamel junction.

In the fluorescent bands it was observed that the outline of the 'calcospherites' was marked by a fluorescent ring. Under high power, within and beyond these areas numerous tubules were seen in which the peritubular zones fluoresced as bright yellow rings around a central dark spot (Figs. 1 and 2). At the peripheral surface of a band, the fluorescence was confined entirely to the peritubular zone and was not detected in the matrix. Microradiographs of these

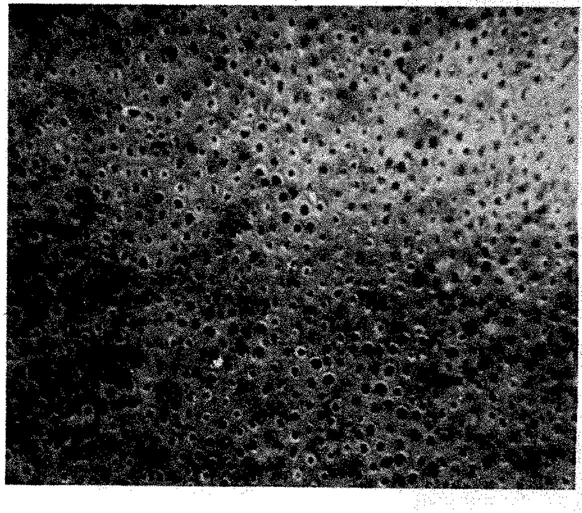

Fig. 1. Photomicrograph (× 500) of transversely cut dentinal tubules, showing well-defined peritubular zones

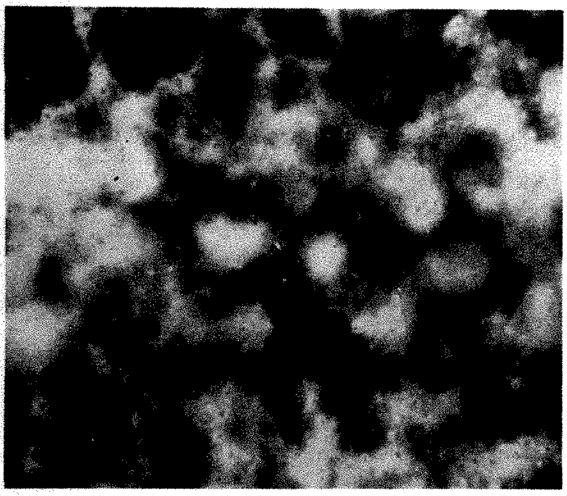

Fig. 2. Photomicrograph (× 500) of the same area as in Fig. 1, showing fluorescence with ultra-violet light. Note fluorescent circular and semi-circular areas in the matrix, and also fluorescence in isolated peritubular zones

areas showed a typical hypermineralized peritubular structure.

Since tetracycline is incorporated in tissue that is calcifying at the time of administration, the distribution of fluorescence in the matrix indicates that calcification occurs in a globular fashion. Furthermore, as the tubules with fluorescent peritubular zones are further from the pulp than the fluorescent matrix, this indicates that the laying down of the hypermineralized peritubular zone occurs at a later stage in dentine development than the mineralization of the matrix. This work tends to confirm earlier observations that the peritubular translucent zone is a manifestation of maturation of the dentine after the mineralization of the dentine matrix proper.

Morphological Changes in Red and Pale Muscles following Tenotomy

In recent experiments one of us[1] has shown that in rabbits the cutting of hind limb tendons produces changes in the pattern of electromyograph activity in a red muscle—soleus—at a time when no change in electromyograph activity can be observed in pale muscles. In conscious rabbits continuous electromyograph activity was recorded from the normal soleus, no matter whether the animal was standing, sitting, or jumping. After tenotomy no electromyograph activity could be recorded when the animal was sitting or standing. Only when the position of the animal was suddenly changed were short bursts of action potentials observed.

We have now carried out experiments to determine some of the structural changes accompanying these functional alterations. After cutting all the tendons around the ankle joint, the animals were killed at varying intervals after the operation, and cross-sections of the soleus and peroneus longus muscles were examined. It is known[2,3] that muscle fibres are only slightly reduced in size three months after tenotomy. In the experiments recorded here we were able to confirm this in the pale peroneus longus, whereas in the red soleus at a similar time after tenotomy most of the fibres have undergone complete degeneration, and those that remain are of very small calibre lying among a mass of fatty and fibrous tissue (Figs. 1 and 2). The degenerative changes in soleus are well advanced by the end of 2–3 weeks (Fig. 3).

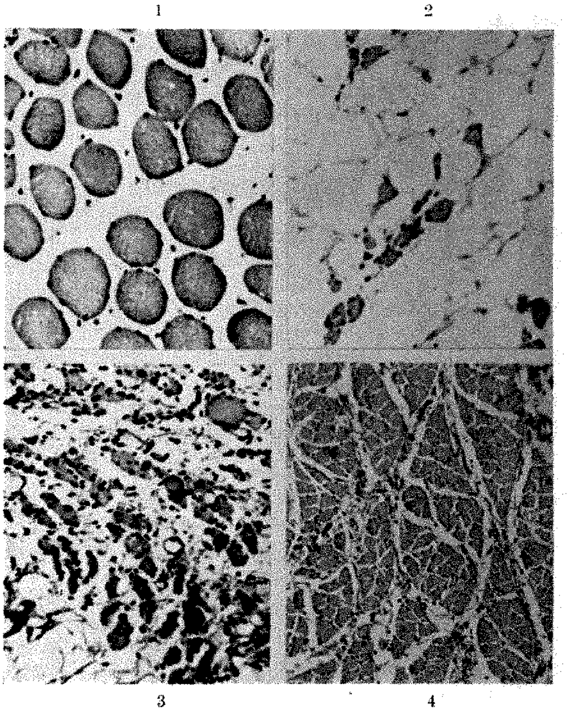

Fig. 1. Normal soleus

Fig. 2. Soleus three months after tenotomy

Fig. 3. Soleus three weeks after tenotomy

Fig. 4. Soleus three weeks after tenotomy and spinal cord section. Apart from the atrophy due to cord section, there are no other degenerative changes

(All stained by Van Gieson. × *c.* 100)

This cannot be explained by suggesting that mechanical stretch is more important for maintaining the structural integrity of red muscles than of pale, as we have also found that when the spinal cord is sectioned at the same time as tendon section the degenerative changes in soleus are negligible (Fig. 4). The finding that much of the degenerative change in the tenotomized soleus can be prevented by simultaneous section of the spinal cord suggests that impulses from supraspinal structures are responsible for the dramatic changes seen in soleus following tenotomy.

RADIOBIOLOGY

Differential Autoradiography of Tritium and Another β-Emitter by a Double Stripping Film Technique

CERTAIN investigations on cellular biochemistry may require examination of the simultaneous incorporation of two metabolites, or of the incorporation of the same metabolite at different times, by the same group of cells. These investigations may be carried out by administering metabolites labelled with two different isotopes—tritium and any other β-emitter—and then distinguishing their distributions on the same autoradiograph, by processing the respective photographic 'grains' to different colours.

In principle the desired result might be achieved by the use of a two-layer emulsion with incorporated colour couplers, the layer adjacent to the histological sample being sufficiently thick to prevent the penetration of the second layer by tritium β-particles. However, this method is likely to lack sufficient resolution and operating flexibility. An alternative method is to superimpose two autoradiographs and to colour the silver 'grains' in one or both emulsion layers by a dye-coupling technique. Coating uniformity and rigid control of coating thickness in the first emulsion layer are essential with this procedure. Initially attempts were made to coat samples by dipping in liquid emulsion, but the irregular surface of the samples (single cells or clumps of cells) interfered with the draining of the emulsion and caused non-uniform coating. It was, therefore, finally decided to use a thin layer of autoradiographic stripping emulsion without any gelatin supporting layer.

The practicability of such a procedure was demonstrated with HeLa cells grown as mono-layers on glass coverslips. The cells were exposed for a short period to tritiated thymidine, then transferred to fresh medium and, after a suitable interval of time, for a second short period to medium containing thymidine labelled with carbon-14. This procedure was designed to provide unlabelled cells, as well as cells labelled with tritium alone, with carbon-14 alone and with both isotopes, on the same coverslip. The specific activities were adjusted so that the time required to produce an autoradiograph of the tritiated compound was about one-tenth that needed for the carbon-14. The cells were histologically fixed with methanol and were stained by the Feulgen technique.

After thorough washing the cells were coated with a uniform layer of autoradiographic emulsion by the stripping-film technique. This was obtained from an experimental coating made without a gelatin supporting layer and having an overall dry thickness before stripping of $3 \cdot 4$–$4 \cdot 0 \mu$. The processed and dried emulsion was $2 \cdot 1$–$2 \cdot 5 \mu$ thick—sufficient to prevent penetration of tritium β-particles. The fragility of this emulsion necessitated some modification of the normal handling technique. An exposure of 24 hr. sufficed to record the tritium distribution, and the emulsion was then processed to give blue dye-coupled 'grains', by bleaching the developed and fixed image and redeveloping in a colour developer. As a result of the lower specific activity of the carbon-14 present, this autoradiograph was produced predominantly by the tritium.

The first autoradiograph was next coated with a thin ($0 \cdot 1 \mu$) layer of celloidin[1] to insulate it chemically from a second stripping emulsion, a Kodak *AR* 10 plate, applied over it. The second autoradiograph, which was produced exclusively by the carbon-14, was processed in the usual way after ten days exposure, to give black grains.

The first emulsion layer contained a well-defined tritium autoradiograph consisting of 'grains' of dye, whereas in the second, *AR* 10 emulsion, there was some loss of resolution due to the separation produced by the first layer. However, despite this loss of resolution, the autoradiograph was sufficiently well defined to distinguish cells containing carbon-14 from other cells. On examination with an oil immersion objective, the two images could be separated by differential focusing. Fig. 1 shows the degree of discrimination observed between cells labelled with one or other isotope, or with both. With

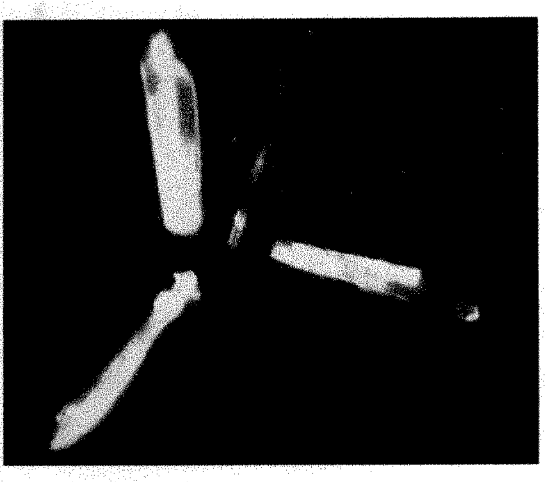

Fig. 2. Crystals from ethanol of the 'brain' hormone. (× c. 17)

obtained from the colourless, active solution in the process of cooling to $-18°$ C.

Using one of the afore-mentioned three parts as material, recrystallization was repeated with acetone and ethanol. 4 mgm. of a crystal was obtained from 3,539 mgm. of crude but active extract of the 'brain' hormone after these treatments (Fig. 2). The melting point of the crystal was 142°–143° C. Both ultra-violet and infra-red spectra were examined.

Thirty-seven days old 'dauer-pupæ' (artificially diapausing, 'brainless' pupæ) of *Bombyx mori* were prepared for use in the bioassay. When 0·02 µgm. of the crystal which was dissolved in 0·01 ml. of ethanol was injected into each 'dauer-pupæ' of *Bombyx mori*, five injected animals emerged respectively as moths on the 22nd (♀), 24th (♂), 28th (♀), 29th (♀) and 35th (♂) day following injection. However, no moth emerged from 38 control animals which were either not injected or mock injected with 0·01 ml. of ethanol without the crystal, for 100 days following pupation.

These results show that the crystal is the most important factor of the active principle of the 'brain' hormone.

We thank Prof. S. Hara, Tokyo College of Pharmacy, Tokyo, for giving us laboratory facilities, and also Y. Ishitoya, H. Akai and Miss K. Tani, Sericultural Experiment Station, Tokyo, for help with the extirpation of pupal brains.

A Change of Phototaxis and a Tropotactic Response by Larvæ of the Mustard Beetle

De Ruiter and van der Horn[1] have reported on changes in phototaxis during the larval life of *Smerinthus ocellata* L. and mentioned the problem of functional significance. Preliminary work by me on the olfactory responses of the larvæ of the mustard beetle, *Phaedon cochleariae* Fab., were hampered for a time by complete reversals of results obtained in earlier replicate olfactometer tests. The cause proved to be a response to light, and experiments similar to those of de Ruiter and van der Horn gave results comparable with those obtained by these authors, with larvæ generally positively phototactic at the beginning of an instar and negatively phototactic at the end. Observations of larval behaviour in the rearing cages showed that larvæ about to moult moved to the darker areas of the food-plant, mainly the underside of the leaf, so that the negative phototaxis shown by the larvæ is probably a response which gives protection during moulting.

After selection for equal aged larvæ in the olfactometer tests an additional response, this time to touch, was observed. In the experimental procedure two larvæ were used at a time, one at each side of a test airstream which occupied the centre of the chamber and contained the odour. A score of 0 or 1 was given, depending on whether the larvæ moved into, or away from, the test air-stream. It was found that a strong bias could be given to the results, for, when the larvæ were transferred to the chamber with a moist camel hair brush, they tended to move away from the side on which they were picked up by the brush. To overcome this, pairs of the 200 larvæ used were transferred in individual tests with the brush alternately on the opposite side of the body.

MICROBIOLOGY

A General Structure for Cell Walls of Gram-Negative Bacteria

The cell walls of a number of Gram-negative bacteria have been shown to contain a mucopeptide component similar in composition to that which forms a major fraction of the cell walls of Gram-positive bacteria[1]. We have recently analysed the cell walls of an *Escherichia coli* mutant 26–26 requiring lysine for growth. A mucopeptide was isolated from cell walls by the procedure described by Mandelstam[2] which contained glucosamine, muramic acid, alanine, glutamic acid, diaminopimelic acid, serine, lysine and aspartic acid as major components. An ethanol-insoluble fraction from trichloroacetic acid extracts of cell-wall preparations contained on hydrolysis all the amino-acids found in the mucopeptide and also ribitol, phosphate and glucose. These results suggest that the cell wall of this organism contains the characteristic mucopeptide and in addition a ribitol teichoic acid[3].

E. coli 26–26, grown in a minimal medium supplemented with sub-optimal amounts of lysine, accumulated inside the cell various precursors of these cell-wall components including uridine nucleotide mucopeptides. It also released into the growth medium uridine and cytidine nucleotides, diaminopimelic acid and lipomucoprotein[4].

The mucopeptide component represents the rigid layer described by Weidel, Frank and Martin[5] in *E. coli B*. They concluded that the cell wall consists of three layers of which the innermost is the rigid mucopeptide and the middle lipopolysaccharide with lipoprotein forming the outermost layer. The uridine nucleotide mucopeptides accumulated by *E. coli*

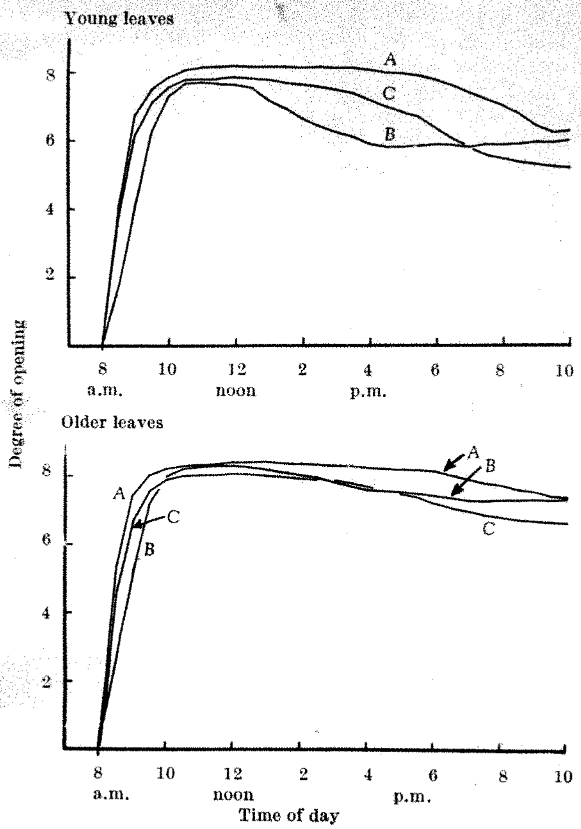

Fig. 1. Stomatal behaviour in illumination of 15,000 lux from 8 a.m. to 10 p.m. Each curve is based on observations on four leaves of different plants. Treatments prior to 8 a.m.: *A*, 8 hr. 15 lux + 8 hr. darkness; *B*, 8 hr. darkness + 8 hr. 15 lux; *C*, 16 hr. darkness. Ordinate scale: arbitrary units of total pressure minus pressure across the leaf, in a resistance porometer, that is, increasing values indicate opening

there was no response to the light in terms of stomatal opening at the time when it was given. It is clear from these and the previous results[1,2] that the 'normal' light responses of stomata, that is, day-time opening in high-intensity light, can to some extent be modified according to the nature of the immediate pretreatment. This leads to the belief that there are two kinds of response to light; first, there is the 'high-intensity' response which operates through changes in carbon dioxide level brought about by photosynthesis[4]; secondly, there is a 'low-intensity' response which is recognizable in after-effects—the opening controlled by carbon dioxide can apparently be modified by a preceding 'low-intensity' treatment; this is probably due to light-induced changes in an endogenous rhythm.

In many species the rhythms of stomatal aperture in light are more pronounced than in *X. pennsylvanicum* (some unpublished experiments have shown that it does not exhibit a true persistent rhythm), and the closure during the first cycle is considerably greater, cf. soybean 'Hernon'[3]. In these the effects described may prove to be of greater importance.

Changes in the pattern of stomatal behaviour involving early 'afternoon closure' could perhaps result in differences in the degree of transpiration and so affect water economy. It might be possible to exert some control over transpiration by suitable manipulation of low-intensity light treatments given at night.

I thank Prof. O. V. S. Heath for very valuable discussion. This work is supported by a grant from the Agricultural Research Council.

ENTOMOLOGY

Crystallization of the 'Brain' Hormone of an Insect

The extraction of the 'brain' hormone from the dissected pupal 'brain' in the silkworm, *Bombyx mori*, was carried out by Kobayashi and Kirimura[1]. Since then about 500,000 'brains' dissected out free of corpora cardiaca and corpora allata of pupæ have been used as material in the purification of the hormone.

We have succeeded in isolating and crystallizing the 'brain' hormone by several treatments of a fraction which is separated by the counter-current distribution from a crude but active extract of the 'brain' hormone as follows.

Crude 'brain' hormone extract was prepared from 220,000 'brains' dissected from *Bombyx* pupæ by the method as shown in Fig. 1.

Several active fractions were separated by means of the counter-current distribution, using the same solvent system as the method of Cole *et al.*[2]. Colourless, active solution was separated from one of the active fractions with petroleum ether (b.p. 40°–60° C.). Three kinds of non-purified parts were separated by organic solvents from the precipitate which was

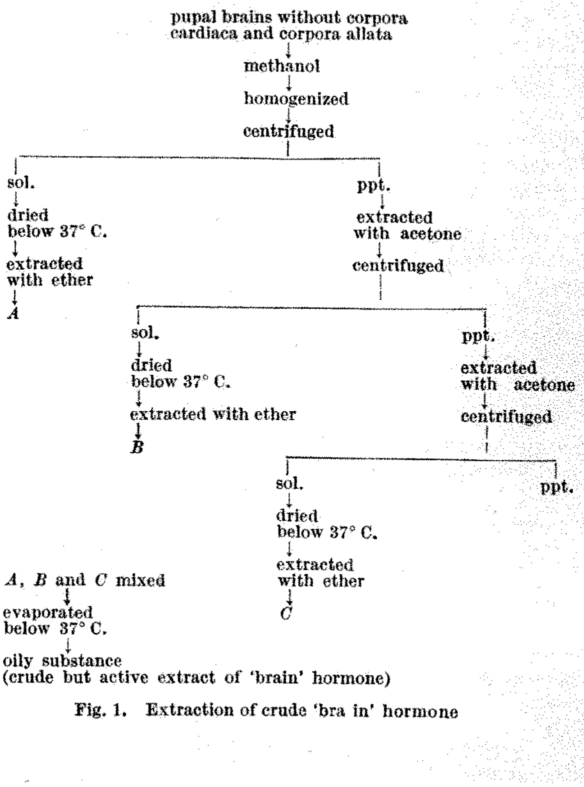

Fig. 1. Extraction of crude 'bra in' hormone

close to 30,000 lb./in.^{2} at the ultimate stress. Although little is known about the mechanical properties of apatite, this is surely more than it could bear in bulk.

In two-phase materials such as fibreglass[5,6] there are fibres having a high modulus of elasticity and a high ultimate tensile strength embedded in a matrix having a low modulus of elasticity and, usually, a low strength. This produces a material with a stiffness intermediate between those of the two components, and with a strength higher than either of the two components. The increased strength is attained because any cracks forming in the stiff fibres, which would normally spread right through the whole structure and cause it to fail, run into the flabby matrix, which will not transmit the crack, but will merely deform.

At first sight, bone appears to be built on a plan contrary to that adopted for man-made two-phase materials: the fibrous collagen is strong, but has a low value for E, and the apatite matrix is weak, but has a high value for E. However, the essential feature of bone from the mechanical point of view is that the apatite does not occur in bulk, with fibres of collagen running through it, but that it is instead in the form of very small crystals. These crystals are of the order of size 500 Å. by 40 Å. (ref. 7), and they can be considered to be very short fibres embedded in a collagenous matrix. This being so, the chances of any particular crystal being large enough to contain a dangerous Griffith crack are small. What cracks there are will spread only under the influence of very high stresses. If they do spread they will immediately run out of the apatite crystals into the collagen, which will deform under their influence, but will not rupture. It is probable, therefore, that the apatite in bone is very strong in tension.

This arrangement requires that the apatite and the collagen should be bound fairly firmly together. At the moment it is not certain what forces are binding the two components. It is possible that it may be simple hydrogen bonding or, though less likely, the small amount of mucopolysaccharide in bone may be acting as a cement.

If this scheme is correct, the great advantage of bone over most of the other heavily calcified skeletal materials found in the animal kingdom is apparent. In other groups the calcifying material is usually in the form of large crystals of calcium carbonate, and so dangerous Griffith cracks can easily form in them. This tendency is carried to an extreme in some echinoderms, in which the crystals may have dimensions of several centimetres, although in this group the crystals have a porous structure that may help to interrupt cracks. Bone combines high strength, particularly tensile strength, with a high modulus of elasticity. The superiority of bone over most other skeletal materials is probably one of the main foundations of the success of the vertebrates.

Stomatal Sensitivity to Low-Intensity Illumination in *Xanthium pennsylvanicum*

EVIDENCE was found in previous work with *X. pennsylvanicum*[1,2] that an endogenous rhythm which influenced the behaviour of the stomata occurred in darkness. The rhythm was shown to be highly sensitive to light and, at 27° C., 10 lux given instead of darkness with sufficient to delay its progress[1].

A recent experiment has demonstrated a somewhat different effect of low-intensity illumination. *Xanthium* plants grown to the eight-leaf stage in the glasshouse in 16-hr. days, consisting of 8 hr. daylight + 8 hr. of low-intensity supplementary light, were placed in controlled condition cabinets (temp. 27° C.) and after an 8-hr. day of high-intensity light were subjected to one of the following treatments: *A*, 8 hr. of 15 lux + 8 hr. of darkness; *B*, 8 hr. of darkness + 8 hr. of 15 lux; *C*, 16 hr. of darkness; these were followed by a period of high intensity light (15,000 lux) during which measurements of stomatal opening were made using an automatically recording porometer[3]. Illumination was from incandescent lamps with a screen of 1 cm. of water, and the intensity was reduced to 15 lux by means of white paper. For each treatment the measurements were replicated on two leaves (5th and 6th) on each of four plants.

There were significant effects of the treatments on the course of stomatal behaviour during the subsequent period of high light. These effects differed according to the age of leaf and consequently the curves of stomatal behaviour in younger and older leaves are presented separately (Fig. 1). It will be seen that in the younger leaves after treatment *B* the stomata began to close early in the afternoon and by 4 p.m. the degree of opening, on the scale used[3], was less than 75 per cent of that in leaves that had received treatment *A* (significant at $P < 0{\cdot}001$). After 4 p.m., however, there was no further closure in *B*, but in *A* the stomata began to close and continued until about 9.30 p.m. After treatment *C* the 'afternoon closure' occurred at a time more or less mid-way between that in the other treatments. A further difference was in the rates of opening after the high light was switched on at 8 a.m.: that in *B* was significantly slower than in *A* and *C*.

In older leaves the effects were less marked; opening after full illumination at 8 a.m. was again significantly slower in *B* than in *A* and *C* but differences in levels of aperture at 4 p.m. were not.

A possible explanation of these effects is that in *A* and *B* a 'light rhythm' commenced when illumination was given after the 8 hr. period of darkness, namely, in 15,000 lux at 8 a.m. in treatment *A*, and 8 hr. earlier, at the beginning of the period of 15 lux, in treatment *B*. Thus the rhythm was out of phase in the two. The fact that the behaviour in *C* differed from both *A* and *B* may have been because the 'dark rhythm', in which the phase is determined mainly by the time of onset of darkness[2], had proceeded for 16 hr. and at 8 a.m. had already reached the 'night opening' stage during which the guard cells had presumably passed into a condition similar to that brought about by light. They would have been in this condition for about 4 hr.[2] prior to 8 a.m., which would explain the finding that the closure in *C* occurred at a time mid-way between *A* and *B*.

These observations are interesting because they provide additional evidence of stomatal sensitivity to low-intensity light. This sensitivity has been detected as after-effects; so far as could be measured brood the eggs to a varying degree, to the single known viviparous species.

This communication records the brooding habit for one additional species, adds some details to the process in another and lists all the occurrences which I have been able to trace in the literature, in the hope that more attention will be given to this aspect of the biology of the Amphineura and that additional cases may be brought to notice.

While examining specimens of *Ischnochiton constanti* (Vélain) collected by the *William Scoresby* off Gough Island in 40–60 fathoms, it was noted that one specimen had a clump of eggs fixed to the branchial groove on each side. The use of the above name for this species, now known from St. Paul and Amsterdam, southern South Africa and Tristan da Cunha and Gough Islands, has been discussed elsewhere[2]. A specimen of *Sypharochiton nigrovirens* (Blainville) from Saldahna Bay, South Africa, collected during the *Discovery* Investigations in the southern hemisphere, proved to have fully developed young clustered under the girdle edge, some 33 on the left side and 22 on the right.

In most species of the Amphineura which have been investigated, eggs and sperm are shed into the surrounding sea water where fertilization and subsequent development occur. There has been some confusion as regards the method of reproduction in the European *Trachydermon cinereus* L., apparently because the details of the process may differ in individuals. From Thorson's[3] summary of the position it now appears that, in this species, eggs and sperm may be released freely into the water, or the fertilized eggs may be extruded in groups which adhere to the substrate, or the fertilized eggs may be retained between the mantle and the gills until they develop into embryos. Thorson believes that the varied method of egg deposition is of slight significance since the embryos all hatch at the same stage in all cases, but in view of the sequence outlined here, this case may perhaps demonstrate how a more persistent brooding habit could develop.

Several species in widely different families have now been recorded as retaining the fertilized eggs within the branchial groove. In some cases the method of subsequent development has not been recorded and it is therefore possible that the developing young may also be brooded by the adult in some of these species.

The brooding of eggs within the branchial groove has been recorded in the following species: *Middendorffia capreanum* (Scacchi) (= *Chiton polii* Philippi)[4], *Ischnochiton imitator* (Smith)[5], *Lepidochitona raymondi* (Pilsbry)[6], *Trachydermon cinereus* L.[3], *Heterozona subviridis* (Iredale and May)[7], *Ischnochiton constanti* (Vélain)[1], *Chiton barnesi* Gray[5], *Nuttalina thomasi* (Pilsbry)[6].

In some cases it has been observed that the eggs and young are retained in the branchial groove until the young have eight well-developed valves. This is true for: *Sypharochiton nigrovirens* (Blainville)[1,8,9], *Hemiarthrum setulosum* Dall[10,11]. Plate[5] has given an account of reproduction in the only known viviparous member of the group, *Callistochiton viviparus* Plate.

The species listed here as demonstrating some stage in the development of viviparity are distributed in four families, the Hanleyidae (*Hemiarthrum*), Ischnochitonidae (*Ischnochiton*, *Heterozona*, *Trachydermon*, and *Lepidochitonida*), the Chitonidae (*Chiton* and *Sypharochiton*) and the Callistoplacidae (*Callistochiton*, *Middendorffia* and *Nuttalina*). It would therefore appear to be a habit which is widely spread systematically in the Amphineura. There is also a wide geographical range for the known occurrences, embracing Europe, the Mediterranean, western North America, southern South America, South Africa, the Subantarctic Islands and southern Australia. It will probably be found to be much more common when the method of reproduction is known for more species. That the habit is no necessary barrier to dispersal is shown by *Hemiarthrum*, which has achieved very wide distribution in the Southern Hemisphere.

Strength of Bone

SURPRISINGLY little attention has been paid to the way in which collagen and apatite, the major components of bone, combine to produce the mechanical properties shown by bone. These properties are not, in fact, what might be expected if the properties of collagen and apatite are the same in bone as they are when considered separately, in bulk.

Ceramic materials are characteristically very much stronger in compression than in tension. Thus heavy-duty electrical porcelain has a compressive strength of about 100,000 lb./in.^{2}, but a tensile strength of only 5,000–8,000 lb./in.^{2} (ref. 1). The reason for this[2] is that minute Griffith cracks in the material cause intense stress concentrations, and so will tend to spread under the influence of tensile stresses, which tend to open up the cracks, but not under the influence of compressive stresses, which will tend to force the sides of the crack together. It is most likely, therefore, that the ceramic component of bone, apatite, would have a low tensile strength in bulk. Collagen, on the other hand, can in certain circumstances have a very high tensile strength, about 80,000 lb./in.^{2} (ref. 3). Collagen has a low modulus of elasticity, E (the modulus of elasticity) being about 200,000 lb./in.^{2}. The value for E for bone is about $2 \cdot 5 \times 10^6$ lb./in.^{2} (ref. 4), which is more than ten times the value for collagen. Therefore apatite must have an elastic modulus that is higher still. Collagen and apatite combine to produce a third material, bone, with a tensile strength of about 15,000 lb./in.^{2}. The compressive strength of bone is about 25,000 lb./in.^{2}.

In an ordinary compound bar, if the two components have the same volume and one has a modulus of elasticity ten times that of the other, then the forces acting on the bar as a whole will be distributed in the ratio 10 : 1 between the components, with the component with a higher value for E bearing the greater part of the force. Therefore, at an ultimate tensile stress of 15,000 lb./in.^{2}, the component with the higher value for E will be bearing a tensile load of 27,300 lb./in.^{2}. If bone is considered to be a compound bar, the apatite should be bearing a load in tension round herrings raises interesting problems concerning the origin of the Dussumieriidae and their relationship to the Clupeidae. The Dussumieriidae can be split into two sub-families (accepting the round herrings as a whole as a distinct family), the more primitive Dussumieriinae and the more clupeid-like Spratelloidinae. From the evidence of pelvic scutes, the latter sub-family could now usefully be divided into two tribes, those with modified and those with unmodified pelvic scutes, for in the latter group, comprising the southern African forms and *S. malabaricus*, the species all share several further characters distinguishing them from *Spratelloides* and *Jenkinsia* (notably the rather advanced pelvics, the lack of a second supra-maxilla, possession of a toothed premaxilla, and a rather different postero-ventral outline to the gill-opening). But except for the first of these differences, the remainder suggest affinities as much with the Dussumieriinae, and especially *Etrumeus*, as with the Clupeidae. It may be that the southern African species are derived from forms which lay close to the original separation of the clupeids and the dussumieriids.

A systematic account of the round herrings is in preparation.

Effect of Abrasion on the Cuticular Scale Pattern of some Mammalian Fibres

The observation that halo-hairs from lambs 2–4 months old showed a waved, crenate cuticular scale pattern not previously described in sheep, and not shown by halo-hairs taken at birth, suggested that the scale pattern had been drastically changed by weathering. Halo-hairs which had developed the crenated scale pattern stained much more readily with methylene blue than did those with smooth scale margins, indicating that gross scale damage may be a factor in the greater affinity for dyes shown by weathered wool.

Fibres from a number of species were treated by rubbing with abrasives (sand paper, jewellers' rouge) and the following alterations were brought about: halo-hairs taken at birth developed the pattern seen in those taken from older lambs; the pattern of the basal region of human hairs (irregular waved mosaic, smooth margins) was converted to a good approximation to the pattern typical of the distal region (wave with ripple to crenate margins); the smooth-margined regular mosaic or diamond petal pattern of the basal part of rat monotrichs and of kolinsky guard hairs was converted to, or towards, a waved, near, crenate pattern. In working on fibres with abrasives it appeared that possibly the lateral edges of the scale wore away first and became invisible, creating a waved pattern, and then the distal margins chipped and wore down, so that the pattern changed towards "near, crenate".

Examination of numerous other fibres and photomicrographs[1,2] confirmed that in all fibres which showed the waved crenate type of pattern this tends to occur distally, the basal or root end almost invariably showing smooth margins and mosaic or petal patterns. Faint traces of the original lateral divisions between scales can often be discerned in the more distal parts. Scale margins of fine wool fibres near the tip in weathered fleeces have been found to show chipping similar to that which produces crenate patterns on coarser fibres, and the scale pattern of sheep face hairs is often waved, near, crenate, except close to the root.

Kassenbeck[3] attributes differences in scale pattern to biomechanical forces within the follicle, and correlates crenate and mosaic scale patterns with ortho- and para-cortex respectively. The facts reported here are not incompatible with his theory that forces within the follicle determine such differences as those between mosaic and petal patterns, but is at variance with his explanation of waved crenate pattern types. If the latter are, as now seems probable, due to external friction acting on the fibre above the skin surface it seems unlikely that they can be associated only with orthocortex as Kassenbeck suggests. Hausman[4] considered that the change in form of the cuticular scales along the length of mammalian fibres is due to greater external friction towards the tips, but did not suggest that crenations and similar irregularities of the scale margins can be produced by wear.

It is concluded from these observations that probably all mammalian fibres have smooth-margined cuticular scales when they emerge from the follicle, and very likely that the patterns are always some form of mosaic or petal; all rippled and crenate, waved patterns being derived from the original patterns by wear. The smooth scale margins of wool and adult kemp of sheep are believed to be due to protection within the fleece. These conclusions are of significance for fibre identification and also in connexion with dyeing and other commercial processing of mammalian fibres; they give further justification for the customary use of the proximal parts of fibres for electron microscopy and chemical tests, and suggest that comparative work on distal regions and on fibres known to have suffered abrasion would be valuable.

Stages in the Development of Viviparity in the Amphineura

The Amphineura are usually considered to demonstrate many primitive features among the Mollusca. It is therefore surprising that more attention has not been given to a study of methods of reproduction in the group. Reference to the reproduction of various species is scattered through the literature; but there have been few attempts since Simroth[1] to give a general account for the group. The sexes are separate, and it is usually stated that fertilization is external, although one truly viviparous species has been long recognized and is usually quoted. It does not appear to be generally recognized that a complete series can be traced within the group from species in which fertilization is external through those which the high-power dry objective, owing to the greater depth of focus, cells containing tritium alone, carbon-14 alone, and both isotopes together are readily distinguished from one another and differential counts can be rapidly carried out.

It was found that even thinner, unsupported emulsions can be handled by the stripping film technique; these would cause less loss of resolution in the second emulsion but are more likely to be penetrated by tritium β-particles. Full details of the above technique and its experimental applications will be published elsewhere.

BIOLOGY

Abdominal Scutes in the Round Herrings (Dussumieriidae)

The Dussumieriidae are usually distinguished from the Clupeidae or true herrings at familial (or subfamilial) level by their lack of abdominal scutes, although one or two modified pelvic scutes have been described (for example in *Etrumeus*[1]). There have been records of fully scuted round herrings; but these all prove erroneous on closer examination. Thus Fowler[2] questioned the inclusion in *Spratelloides* of *S. madagascariensis* Sauvage because the original figure[3] shows the ventral profile with unmistakable scutes. But Bertin[4], in re-describing this species, is emphatic: "Cette carène n'existe pas". Smith[5], evidently accepting Sauvage's figure rather than Bertin's description, made *S. madagascariensis* the genotype of *Pellonulops* Smith, which he described as having 19–20 scutes (that is, both before and behind the pelvic fins). I have now examined one of the two syntypes of *S. madagascariensis*, and there are in fact no abdominal scutes other than the single pelvic scute found in all Dussumieriidae. The "hard, sharp keel on the thoracic region in front of the pectorals" in *Gilchristella aestuarius* (Gilchrist) mentioned by Barnard[6] is not due to scutes, but is formed of the lower edges of the two cleithra meeting in the mid-line; in some specimens it is quite pronounced.

In revising the round herrings, I have found a useful division can be made according to the form of the pelvic scute. In the first, or modified, type there is a W-shaped scute immediately anterior to the pelvic fins, the arms of the W extending laterally round the base of the fin rays. This type is described and figured by Chapman[1] and is shown in Fig. 1. It is found in *Etrumeus*, *Dussumieria*, *Spratelloides* (except *S. malabaricus*—see below) and in *Jenkinsia*. In *Etrumeus*, but apparently not the other genera, there is also a second, oval scute lying immediately behind the pelvic fin base.

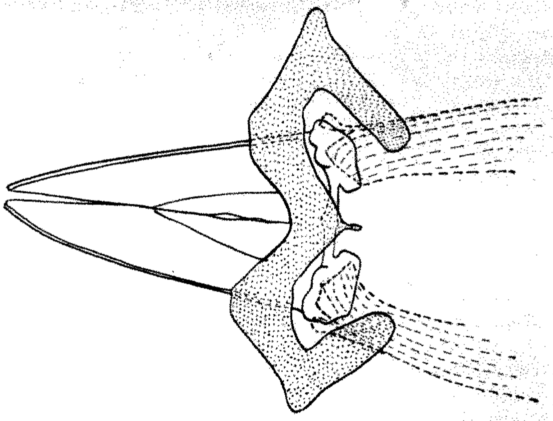

Fig. 1. Ventral view of the modified pelvic scute (stippled) in *Spratelloides delicatulus*. Pelvic fin-rays indicated by broken lines

The second type of pelvic scute, here termed the unmodified type, closely resembles the normal clupeid scute. The base lies immediately anterior to the pelvic fins, but laterally there is a vertical ascending process which is flat and pointed at its tip (Fig. 2). The unmodified type is found in the South African and Madagascar species, *Spratellomorpha bianalis* (Bertin), *Gilchristella aestuarius* and *G. madagascariensis*, and also occurs in *Spratelloides malabaricus* Day of India. The unmodified pelvic scute of *S. bianalis* was figured and mentioned by Bertin[4], but he described it as "l'écaille qui précède cette nageoire"; the scales in fact overlie the scute.

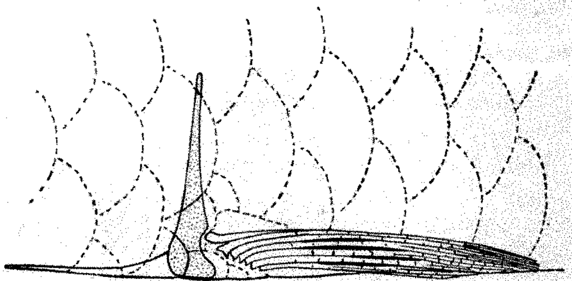

Fig. 2. Left lateral view of the unmodified pelvic scute (stippled) in *Spratelloides malabaricus*. Scales indicated by broken lines

Hitherto, confirmed records of scutes in the Dussumieriidae have been confined to a single pelvic scute, with one case of a second pelvic scute behind this fin. But in two specimens of *G. aestuarius* in this Museum, both from Durban (B.M.Reg. No. 1915.7.6.3 and 1919.9.12.3), there are 6 or 7 unmodified scutes lying in series from just behind the pectoral fins to about four-fifths the distance to the pelvic base (Fig. 3). These scutes, like the unmodified pelvic scutes, have thin, pointed ascending arms and are not keeled but rounded ventrally. Their presence is not easily detected until the specimen has been allowed to dry out somewhat.

If these two specimens are not merely chance mutations, then the presence of true scutes in the

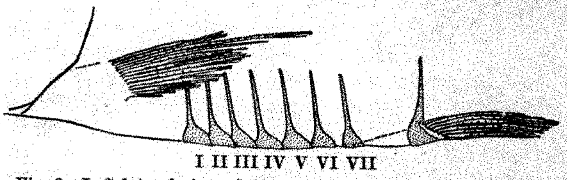

Fig. 3. Left lateral view of the unmodified pelvic and abdominal scutes (stippled and numbered I–VII) in *Gilchristella aestuarius*

26–26 are most likely to be precursors of the rigid layer and we believe the lipomucoprotein found in the growth medium to be fragments of the two outer layers

The Gram-positive bacterial cell wall is clearly visible in electron micrographs as an outer layer distinct from the cytoplasmic membrane It has always been more difficult to distinguish between the cell walls and cytoplasmic membranes of the Gram-negative bacteria

We should like to suggest that our findings and those of Weidel are compatible with the hypothesis that the surface layers of these organisms consist of two 'unit' membranes with a rigid layer in between This is analogous to the double membranes formed by the folding back of the 'unit' membranes to form myelin sheaths in nerve fibres[6] Each membrane would have the 'unit' membrane structure of protein–lipid–lipid–polysaccharide This would allow for a 'cytoplasmic membrane' of this structure, surrounded by a 'rigid wall' composed of mucopeptide and probably teichoic acid, and an 'outer membrane' with the membrane layers reversed to give polysaccharide–lipid–lipid–protein

This structure is consistent with the layers to be seen in electron micrographs of *E coli* by Kellenberger and Ryter[7] and more recently by Murray[8] It is suggested that the rigid layer could be linked to either the inner or outer membrane, giving either but not both membranes the appearance of rigidity

Recently, Brown, Drummond and North[9] have shown that two distinct membranes can be seen in electron micrographs of whole cells and spheroplasts of the marine pseudomonad N C M B 845 We would therefore suggest that a double membrane surface structure may be characteristic of all Gram-negative bacteria

Transmissible Drug-resistance Factors and Formation of Multiple Resistance

IN earlier reports several types of drug (chloramphenicol, *Cm*, tetracycline, *Tc*; streptomycin, *Sm*, sulphanilamide, *Da*) resistant *Escherichia coli* and *Shigella* were described[1-3] It was also found that seven types of drug resistance are transmitted by cell-to-cell contact[4]

According to the facts that these types of drug resistance are infectively transmitted and eliminated spontaneously or by treatment with acriflavin[5], the presence of transmissible drug-resistance factor (*R*) has been assumed

We are concerned in this communication with the linkage of *R* (*Tc*) and *R* (*Cm Sm Sa*) and formation of *R* (*Cm Tc Sm Sa*) factor *E coli K*–12 substrain *PA*200 F^- auxotroph resistant to (1) tetracycline, and (2) chloramphenicol, tetracycline, streptomycin and sulphanilamide, and *Shigella flexneri* 3*a* 86 resistant to (1) chloramphenicol, streptomycin and sulphanilamide, and (2) chloramphenicol, tetracycline, streptomycin and sulphanilamide were used All the strains used were able to transmit their drug resistance by mixed cultivation

E coli K–12 strain F^+ prototroph were used as the recipient of the drug resistance by mixed cultivation The temperate phage *P1kc* which adapted to *E coli K*–12 F^+ prototroph was used in the transduction of *R* factor

The cells were collected after over-night culture in Difco brain-heart infusion broth at 37° C One ml of this culture was inoculated into 9 ml brain-heart infusion broth at 37° C in Monod's shaker for 3 hr When the growth reached the middle of logarithmic phase, 1 ml of the donor cell culture was inoculated mixing in 9 ml of the recipient cultures at 37° C in a Monod's shaker The ratio of the donor to recipient of the drug resistance was approximately 1 10 The total number of cells in mixed cultivation was c 10^9/ml , and the increase in number of bacteria was not observed during the incubation of mixing culture (Fig 1)

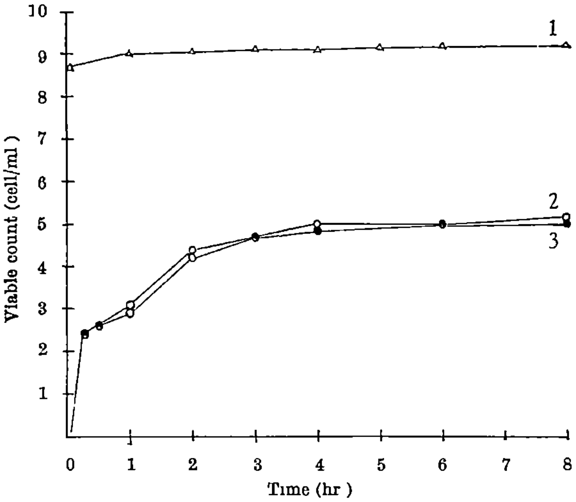

Fig 1 The time course of the transmission of tetracycline resistance and formation of multiple resistance *E coli K*-12 *PA* 200 F^- *R* (*Tc*) and *E coli K*-12 F^+ prototroph *R* (*Cm Sm Sa*) were mixed at time 0 At different intervals of time samples were plated on *ALGa* agar containing tetracycline or chloramphenicol and tetracycline to select the recipient *E coli K*-12 F^+ prototroph, which acquired tetracycline resistance 1, Total number/ml of cells in mixed cultivation, 2, number of cell/ml of *E coli K*-12 F^+ prototroph on *ALGa* agar containing 25 μgm tetracycline, 3, number of cell/ml of *E coli K*-12 F^+ prototroph on *ALGa* agar containing both 25 μgm /ml of chloramphenicol and tetracycline

At desired intervals, an aliquot of the sample was withdrawn, diluted with buffered saline (*p*H 7 2) and streaked on selective media to obtain the recipient cells which acquired drug resistance by mixed cultivation

Medium *ALGa* agar containing drugs was used for the selection of *E coli* from the mixed culture, while *AGGa* agar containing drugs was used for the selection of *Shigella flexneri* 3*a* The *AGGa* agar consists of 1 l of medium *A* agar (ref 6), 5 gm of glucose and 10 gm of sodium glutamate The *ALGa* agar has the same composition with the exception of 5 gm of lactose instead of glucose

The transmission frequency of drug resistance was calculated by dividing the number of recipient cells per ml which acquired drug resistance by the number of donor cells per ml input

For the transduction of the drug-resistance factor *R*, the method described by Lennox[7] was adopted, and for the selection of the transductants which acquired drug resistance, the heart infusion agar plates containing chloramphenicol (25 mcgm /ml), tetracycline (25 mcgm /ml) and streptomycin (25 mcgm /ml), respectively, and synthetic agar plate containing sulphanilamide (100 mcgm /ml) were used

The time course of the transmission of tetracycline resistance to *E coli K*–12 F^+ prototroph *R* (*Cm Sm Sa*) is shown in Fig 1 The transmission frequency of tetracycline resistance to *Sh flexneri* 3*a* 86 *R* (*Cm Sm Sa*) after 4 hr incubation was 10^{-4} [2]

A single colony of the recipient *Sh flexneri* 3*a* 86 which acquired tetracycline resistance and became resistant to four drugs (R_4), namely chloramphenicol, tetracycline, streptomycin and sulphanilamide, was purified by three successive single colony isolations from plates containing both chloramphenicol and tetracycline, followed by three successive inoculations in brain-heart infusion broth

The brain-heart infusion cultures were streaked on normal agar plate The drug resistance of 875 single colonies thus obtained was determined, and all were proved to be resistant to four drugs By the acridine treatment, resistance to four drugs was eliminated and no segregated loss was found

The resistance of *Sh flexneri* 3*a* R_4 to four drugs (chloramphenicol, tetracycline, streptomycin and sulphanilamide), obtained from the mixed cultivation of *Sh flexneri* 3*a* R_3 (chloramphenicol, streptomycin and sulphanilamide) with *E coli K*–12 R_1 (tetracycline), was also transmitted by mixed cultivation and made the recipient cells resistant to the four drugs

The recipient cells showed no segregation of resistance to the four drugs regardless of the difference of selective media The transmission frequency of resistance to the four drugs thus obtained was identical to that of the *Shigella* strain resistant to four drugs obtained from the fæces of humans by mixed cultivation with *E coli K*–12 F^+ prototroph, and no segregated transmission was found in retransmission of resistance to the four drugs thus formed by agitation with blender treatment

The resistance to four drugs which was produced by mixed cultivation of *Shigella* with *E coli* was transmitted to *K*–12 F^+ prototroph The multiple resistance of *K*–12 prototroph thus obtained was transduced by the phage *PIkc* to *K*–12 F^+ prototroph

From these results it would seem possible that R_1 (*Tc*) and R_3(*Cm Sm Sa*) factors become linked when the *R* (*Tc*) factor is infectively transmitted to the cells containing *R* (*Cm Sm Sa*) factor and the cells become resistant to the four drugs

GENETICS

A Body Colour Mutation in the German Cockroach

For many years various cockroach species have been used extensively as experimental animals, particularly in physiological investigations and, more recently, in studies on insecticide resistance Generally speaking, however, there is little known concerning the genetics of cockroaches For some time we have carried out a search for heritable traits in the German cockroach, *Blattella germanica* (L), along a somewhat similar line to that conducted in the mosquito, *Aedes aegypti*, by Craig and VandeHey[1,2] An autosomal recessive, balloon-wing[3], and a tergal abnormality[4] have already been described The genetics of an orange-body colour mutation (*or*) is presented here, as well as the results of tests for linkage of this trait with balloon-wing (*ba*) Crosses with a DDT-resistant strain were also made, but the results are presented elsewhere[5]

Phenotypic expression of the orange-body mutation appears to resemble most closely that of brown body (*bwb*) in *Musca domestica*[6] and yellow in *Drosophila melanogaster*[7] It occurred spontaneously and was first detected in a laboratory strain from Orlando, Florida It was later noted to occur with varying frequency in a number of other laboratory strains, some originating from widely separated geographical localities in the United States *Or* nymphs were separated from these strains and a pure-breeding colony was established. Crosses were then made with wild-type and balloon-wing individuals for genetical study The sexes were separated as nymphs by the method described by Ross and Cochran[8], and matings were made soon after the insects matured

The *or* mutants are easily distinguished from wild-type cockroaches in all post-embryonic stages, although the difference in colour is most striking in nymphs The mutant nymphs are a bright, orange-brown colour Wild nymphs appear black to the naked eye, except for a small, yellowish area on the thorax *Or* adults are lighter and more of an orange-brown colour than wild-type adults They are most readily distinguished by brown, rather than black, longitudinal bands on the pronotum Both *or* and wild-type females have a darker body colour than the corresponding males Hybrids are indistinguishable from wild-type in body colour

In the crosses with wild-type cockroaches, it was found that *or* acts as a simple recessive The results are summarized in Table 1 There was no significant difference between the reciprocal crosses and no significant deviation from a 1 1 sex ratio Consequently, neither reciprocal crosses nor sexes are listed separately Statistical deviations from the expected 1 1 ratio for *or* × hybrid (Table 1, III) and 3 1 ratio for hybrid × hybrid (Table 1, IV) were well within the expected range of variation ($\chi^2_1 = 0\ 31$, $P > 0\ 50$, and $\chi^2_1 = 0\ 44$, $P > 0\ 50$, respectively)

Table 1 Results of Various Crosses involving Orange-Body and Wild-Type German Cockroaches

	Mating	No of crosses	No of wild-type of offspring	No of *or** offspring
I	*or* × *or*	13	0	400
II	*or* × wild	7	255	0
III	*or* × hybrid	10	189	200
IV	hybrid × hybrid	20	441	156
V	hybrid × wild	6	227	0

* *or*, Orange body colour

In the F_2 from a single cross between *or* and wild-type, the results were so peculiar as to warrant special attention There were 337 wild-type and 7 *or* progeny, an approximate ratio of 48 1 instead of the expected 3 1 In an attempt to investigate this occurrence, a series of 56 crosses (largely backcrosses with *or*) covering 4 generations were made The deficiency of *or* offspring proved to be heritable Evidence was obtained that the deficiency is expressed only when the male parent is the carrier A ratio of 28 1 was common in these crosses The female parent also transmits the deficiency, which is then expressed again through the male offspring

The results of these crosses do not allow a satisfactory explanation of the deficiency of *or*, but its occurrence may indicate the presence of a factor(s) epistatic to *or*, or an instability in the *or* locus The frequent appearance of these peculiar ratios would, of course, detract from the value of *or* as a genetic marker Thus far, however, the occurrence is limited to the offspring from a single mating of an *or* female × a wild-type male It appears, therefore, that if care is used this orange-body mutation will be a useful marker

A series of crosses between *or* and *ba* roaches were made to test for linkage In the F_1 all offspring were wild type in appearance, as would be expected since both traits are recessive When the F_1 hybrids were mated, the resulting F_2 did not deviate significantly from a theoretical 9 3 3 1 ratio The results are as follows 524 wild-type wing and body colour 167 wild-type wing, *or* 179 wild-type colour, *ba* 55 *or, ba* The χ^2 goodness of fit test gave a $\chi^2_3 = 0\ 62$, $P > 0\ 80$ These results indicate that *ba* and *or* are independent factors A true-breeding colony of balloon-wing, orange body colour cockroaches has been established from the F_2 individuals showing these traits

VIROLOGY

An Equine Respiratory Virus with Enterovirus Properties

A VIRUS was isolated in monkey kidney tissue cultures from the fæces of 13 of 290 horses held in the stables of the Wellcome Research Laboratories One of these strains was selected for investigation Rabbit hyperimmune serum prepared against it and possessing a neutralizing titre of 1/4,000 neutralized all 12 remaining isolates to the same titre

The virus grew readily in kidney cultures from several monkey species and rather less readily in dog kidney and *HEp*-2 tissues Titres of 6 5 to 7 5 $\log_{10}$ TCD_{50}/1 ml of tissue culture fluid were attained The cytopathic effect was indistinguishable from that of poliovirus, no inclusion bodies were found The virus was resistant to ether, chloroform and fluorocarbon ($C_2Cl_3F_3$) Ultracentrifugation, and electron microscopy of phosphotungstate negatively contrasted concentrates indicated a particle diameter of 30 mμ, there was a similarity to poliovirus in the general shape No detectable drop in titre resulted from 12 months storage in a serum-free medium at − 20° C One week at 22° C caused the titre to fall from 7 5 to 6 8 $\log_{10}$ $TCID_{50}$/0 5 ml No hæmagglutination or hæmadsorption by infected tissue occurred at 4° C room temperature or 37° C , using erythrocytes from rhesus or cynomolgus monkeys, and from man, cat, dog, horse, ox, rat, ferret, guinea pig or chick

No neutralization of 100 $TCID_{50}$ of any of the *ECHO* viruses 1–28 nor of Coe virus by a rabbit antiserum having a titre of 1/800 against the equine virus was demonstrable No relationship with polioviruses I, II, and III was detected by cross-neutralization tests Intracerebral or subcutaneous inoculation of suckling mice produced no pathological effect Virus could not be isolated in tissue culture from brain or muscle of mice inoculated 13 days previously These results suggest that the virus is not a member of the Coxsackie group

It has been demonstrated[1] that the virus is common among horses and reproduces in experimentally infected horses in the tissues of the pharynx, causing a mucoid or mucopurulent reaction, accompanied by a nasal discharge A viræmia, lasting 4–5 days and often accompanied by pyrexia, regularly occurred No evidence was found for reproduction in the tissues of the gut The virus was found in the fæces of infected animals in only small quantities and probably originated from the pharyngeal region

High antibody titres (1/512–1/1,024) to the virus were present in the sera of 3 of 12 stable workers, indicating that the virus is able to infect man None of 59 non-stable workers or 100 young Swiss military recruits possessed antibody Attempts to infect 5 cynomolgus monkeys by means of a stomach tube were unsuccessful, as indicated by a lack of antibody development However, each of 5 young adult cynomolgus monkeys, including one from the previous experiment, were found to have developed antibody titres of 1/1,024 or greater one month following intranasal administration of the virus These animals showed no respiratory symptoms Two older monkeys developed slight mucoid discharge from the nostrils, accompanied by nasal râles, on the third day following intranasal inoculation, lasting 3 days

The properties of this virus are apparently rather similar to those of Coe virus (Coxsackie *A*21) and the rhino-viruses of man In contrast to the common cold viruses, however, the equine virus is able to grow equally well at the general body temperature of its host, the horse, as at the somewhat lower temperature of the upper respiratory tract Temperature therefore cannot account for the seeming inability of the virus to reproduce in the gut

The physical properties of this agent and its behaviour in tissue culture indicate that it is a member of the enterovirus group, despite the localization of its reproduction to the respiratory region rather than the gut The naming of this virus is not easy, as 'equine respiratory enterovirus' is apparently self-contradictory, although the 'enteron' does include the pharynx This difficulty emphasizes the need for reconsidering the classification and nomenclature of the small ether-resistant viruses and the adoption of a system which will embrace the non-human enteroviruses and the 'respiratory enteroviruses'

I thank Dr A P Waterson of the School of Pathology, University of Cambridge, for carrying out the electron microscopy

Apple Virus Inactivation by Heat Therapy and Tip Propagation

THE presence of many viruses latent in apple varieties and rootstocks has been shown by the use of indicator plants such as Virginia Crab, Spy 227, and *Malus platycarpa* Three of these viruses which on *M platycarpa* produce symptoms of line pattern (= chlorotic leaf spot), dwarfing and scaly bark have been shown to be widely distributed No virus-free source was found of many of the apple varieties and rootstocks grown commercially in England

Experiments were therefore started in 1958 to try to inactivate these viruses by heat therapy, a method which had proved successful in similar work with some strawberry and raspberry viruses

A cabinet was used in which the air temperature was controlled at 37° ± 2° C and young apple trees were grown at this temperature for 10, 15, and 20 days Buds from the extension shoots, produced while the trees were in the cabinet, were afterwards retested on *M platycarpa*, using the double-budding method of virus indexing The results shown in Table 1 suggested that the viruses in the deep-seated tissues were not inactivated by any of these treatments, for although some initial improvement was seen, this was not maintained and systemic reinfection was rapid At the end of the test year the virus content of the treated plants was the same as that of the controls

Table 1

	Heat treatment (days)	No of clones treated	No of clones virus-inactivated
No tip propagation	10	12	—
	15	9	—
	20	7	—
Tip propagation	20	22	7
	23	25	10
	30	9	4

A method of isolating the growing tip from the heat-treated plant as soon as possible after treatment was therefore developed The extreme tip (1 cm) of the young shoot was wedge-grafted into a young apple seedling of the same diameter The tiny graft was held in position by self-adhesive crepe bandage and enclosed in a small polythene bag Propagation is possible in this way at any time of the year but most success was achieved with grafts made in the spring, when about 90 per cent grew

The results after heat treatment and tip propagation are also shown in Table 1

It can be seen that the introduction of tip propagation after heat treatment proved successful in more than one-third of all the clones treated Success is not related to the duration of the heat treatment, since it appears possible to produce healthy clones after 20 days, yet some still carry infection after 30 days

The important factor seems to be the growing-away from the virus rather than the complete inactivation of all the virus present It is therefore necessary to produce very rapid growth under conditions unfavourable to virus multiplication and to isolate the young tip as soon as possible after treatment Tips from control plants not heat-treated were still infected when re-tested

Some of the apparently healthy clones may become re-infected from deep-seated virus at a later date It is also possible that the virus concentration had been reduced to such a level that no symptoms appeared on the indicator plants Since a fairly long period (1½ years) has elapsed, however, since heat treatment, neither of these possibilities seems likely, nevertheless periodic tests will be necessary to confirm freedom from infection

As a clone can be rapidly built up from one individual by vegetative propagation, the heat treatment and tip propagation need be successful in only one individual of each variety and rootstock The clonal descendants from such an individual should remain free from these viruses indefinitely, if contact with infected material is avoided, since there is, as yet, no evidence to indicate their spread in the orchard by other means

Use of Goose Cells in Hæmagglutination Tests with Louping ill Virus Antigen

PORTERFIELD[1] recommended the use of goose red blood cells for hæmagglutination and hæmagglutination inhibition (H A I) tests with arborvirus antigens Such tests are susceptible to non-specific inhibition by lipids present in normal animal serum[2,3] These non-specific inhibitors are widely distributed[4], but little is known of their nature or mode of action

Porterfield and Rowe[5] investigated a number of purified phospholipid fractions of human red cells and found that the inhibiting activity against several Group *B* arborvirus antigens was associated with certain choline-containing phospholipids related to lecithin Lecithin itself extracted from hen's eggs was a powerful inhibitor, but they were unwilling to accept the explanation that lecithin itself was the active component, in view of the fact that one fraction without activity in hæmagglutination inhibition was the richest in lecithin by chemical tests, and egg lecithin had only 0 5 per cent of the activity of other fractions

In the course of carrying out hæmagglutination inhibition tests on sheep serum[6] with a louping ill virus (Group *B*) antigen we noted that the goose cells used in the tests became inagglutinable when egg laying commenced in April 1961, and remained so during the egg-laying period, agglutinability returning some time after egg laying had ceased The goose cells from this bird again became inagglutinable on October 5, 1961, when egg laying again occurred At the same time non-specific inhibitor, normally present in goose and gander serum, was no longer detectable in the goose (Table 1) These inagglutin-

* Egg-laying period

able goose cells were subjected to various treatments in attempts to reverse the inagglutinability Short-term time-temperature exposures in borate saline to varying pH (5 75–8 7), salt concentration (0 5–2 per cent), trypsin, lecithinase (*Cl welchii* type *A* toxin), and incubation with gander serum failed to render the cells agglutinable Lecithinase added to goose serum induced a marked opalescence in these samples of goose serum devoid of demonstrable non-specific inhibitor, but did not reveal the presence of a lecithin masked inhibitor Gander cells which were always agglutinable could be rendered inagglutinable by exposure to lipid extracted from goose serum or goose egg yolk, and could not be restored to agglutinability by washing with saline Non-specific inhibitor reappeared in the serum simultaneously with the cessation of egg laying, but the red cells remained inagglutinable for a further 39 days

PSYCHOLOGY

Eyelid Reflex Response to Stretch

AMONG the evidence of consciousness in the human subject, the position of the upper eyelid fulfils a significant role, and varies with the degree of attention[1] It is of interest, therefore, to understand the mechanisms causing eyelid movement and particularly the relationship of local automatic reflexes to this function Consciousness generally also invokes much ocular work both of movement and of visual function, but it has been found that the muscles controlling the position of the eye do not appear to possess simple stretch reflexes[2], nor does proprioceptive information appear to reach a conscious level[3]

Nevertheless, stretch reflexes are possessed particularly by those muscles subserving an anti-gravity function The upper eyelid may be considered to fall into this category

We have examined the response of the upper eyelid to sudden displacements applied extrinsically, and found a reflex contraction in opposition to displacement, which forms part of a more complex response Our method was to record the position of the upper eyelid by means of a transducer device[4], the lever of which was adherent to the upper eyelid Displacements of a given amount were produced by an electromagnet acting on a piece of ferrite attached to the lever, which was otherwise free to move In order to make good mechanical attachment with the eyelid, a curved piece of 'Perspex' was stuck firmly to a large area of the lower margin of the eyelid including the eyelashes By means of such a connexion the force could thus be distributed evenly over most of the eyelid The movement of the contralateral eyelid was simultaneously recorded

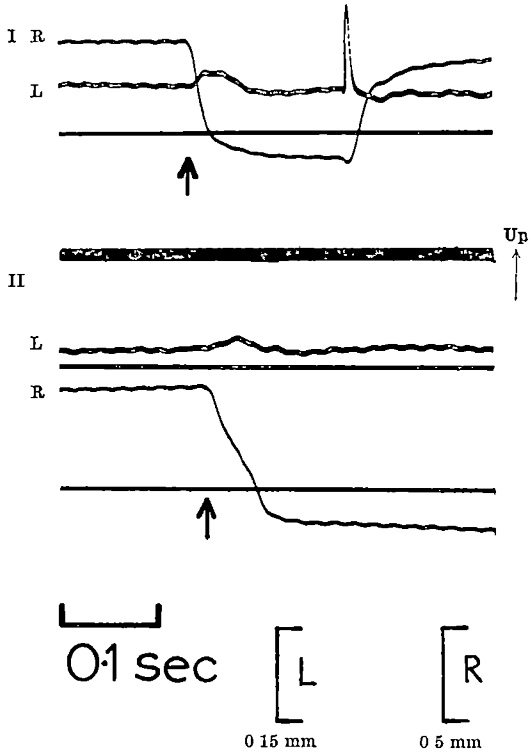

Fig 1 Two records (I and II), each showing simultaneous movement of left and right upper eyelids Downward displacement applied to right eyelid at arrow

We found that the movement of the eyelid to which a downward force had been applied always showed a clear hesitation and delay on the falling slope of the record (Fig 1) The delay in fall thus introduced varied in duration from 70 to 100 msec This check in the downward movement must have been produced by contraction of the levator palpebræ superioris Further evidence for this response was obtained from the other eyelid, which in the human subject shows a high degree of linkage and synchronism[4] The record showed a small contraction to occur during the time of active contraction of the displaced eyelid While a degree of uncertainty exists as to the point of onset of active contraction in the displaced eyelid, it appears that the contraction in the contralateral lid was synchronous with or preceded the displaced lid The relative values of movements were such that a downward sustained displacement of 1 mm evoked a raising of the contralateral lid of 0 1 mm The complete responses of the lids in fact form part of a complex pattern of alternating excitation and inhibition

The stretch response of the upper eyelid may form part of the intrinsic pattern of function of anti-gravity muscles during consciousness It may be considered advantageous during the wakeful state to limit the amount of control referred to the conscious level, by the provision of local controls (stretch reflexes) We may regard the eyelid stretch reflex to be in this category, and to provide some degree of control of position at a low level, while only relatively important decisions are referred to higher brain levels for conscious consideration

Perception of Topographical Information (with Reference to Road Signs)

AN experimental study has compared six layouts of advance road direction signs This communication is concerned with three of these, at present displayed in Great Britain, the Continent and the United States On the first two designs, a road intersection is represented by a diagram on the display, road numbers and place-names are enclosed in rectangular boxes on the British layout, without boxes on the Continental design On the American display the destinations are listed and short arrows at the side indicate direction The distance legibility is greatest for the American type, then the Continental, and the British signs are least legible when signs are compared on back-boards of equal area[1] The order appeared to be determined by the size of lettering The present experiments tested the effect of the difference in the displays on accuracy and speed of interpretation

Signs describing a route with junctions of different complexity were drawn in each of the layouts Subjects sat 9 ft from a screen and off-set 1 4 ft to the right A projection tachistoscope displayed the signs, with black on white contrast, 1/10th to scale for intervals ranging from 0 5 to 2 sec This gave some similitude to the visual angle at which drivers view signs Subjects responded to the signs either by drawing the direction necessary to attain a previously designated destination, or by moving a control stick Throughout the experiment they performed a compensatory tracking task as a substitute for driving, with the tracking display set normal to the subject Performance was measured by (*a*) response-time between the presentation of the sign and the subject's response with the control stick, (*b*) errors of drawn directional movement, (*c*) indirect effects of the sign layouts on an error score on the tracking task In separate experiments, signs in three layouts, selected from all those tested, were compared The sign layouts were presented in a counter-balanced order and a subject followed the route three times

In a subsidiary experiment, signs were briefly exposed to subjects who were required to draw a diagram of the junction represented immediately afterwards, and indicate the direction necessary to reach a destination The diagrams were scored for accuracy

Table 1 SCORES ON RESPONSE MEASURES TO DIRECTION SIGNS IN THREE LAYOUTS

Response measures	Layout British	Layout Continental	Layout American	No of signs per layout	No of subjects per cell
Mean log response time	2 2132	2 1291	2 1365	6	18
Errors of directional movement	43	26	17	9	27
Errors of reproduction	36	39	70	12	12

The tracking task scores showed no difference between layouts Table 1 shows the results of the other measures, significance was tested by analysis of variance

There were more errors of directional movement and a longer response time to the British layout Caution is required in interpreting the latter result as response time was partially determined by interaction effects between the British layout and the others with which it was compared Errors of reproduction were greatest on the American layout, although on all layout errors were more numerous on complex signs On the American layout four-fifths of the attempts at reproducing the complex signs were unsuccessful

These results showed that it was possible to scan and select a direction from a Continental or American sign with almost equal facility, but on the latter layout the numerous errors of reproduction on the complex signs demonstrated that the topographical displays convey an erroneous message about the layout of the crossroads the observer will meet However, before simple junctions, the American list layout may be optimal as it permits larger lettering It was concluded that before simple junctions there are advantages in displaying the Continental or American layouts, before complex junctions, the Continental design with a diagram of the approaching junction is desirable

Part of the problem of designing topographical displays is to emphasize significant details to aid visual resolution, but cognitive processes of interpretation are also important The individual, in route finding, has to locate his own geographical position and to have the intention of proceeding to another known position In doing so, he has the aid of symbolic representations in the form of topographical displays The individual has to match the symbolic representation with the geographical layout, either directly or from memory of the representation, which requires the selective use of environmental cues Bartlett[2] has described the ideational content of direction finding from road signs, placing emphasis on the general anticipatory function of the symbols The present results suggest that not only may the symbols be changed to aid discrimination, but the form of the layout may reduce conceptual work Emphasis on discriminability and the presentation of optimum configuration or 'Gestalten' can present different design problems which are not always easy to reconcile

The work was carried out in collaboration with the Road Research Laboratory I thank Mr J W Whitfield for directing the work

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned

Assistant Lecturers (2) in Pharmacy—The Registrar, The University, Manchester 13 (August 8)

Biochemist, for research on nucleic acids in normal and abnormal embryonic cells—The Secretary, University College, Gower Street, London, W C 1 (August 10)

Lecturer or Assistant Lecturer in the Department of Veterinary Pathology, Royal (Dick) School of Veterinary Studies—The Secretary, The University, Edinburgh (August 10)

Lecturer (preferably with special interests in fluid dynamics or numerical analysis) in Applied Mathematics in St Salvator's College—The Secretary, The University, College Gate, St Andrews, Fife (August 11)

Assistant Lecturer or Research Demonstrator in Physics—The Secretary, Queen Elizabeth College (University of London), Campden Hill Road, London, W 8 (August 13)

Lecturer in Computer Science—The Secretary, Birkbeck College (University of London), Malet Street, London, W C 1 (August 13)

Research Curator in Geology—The Professor of Geology, Sedimentary Research Laboratory, The University, Whiteknights Park, Reading (August 13)

Lecturer (Biochemist) in the Department of Medicine at the Western Infirmary—The Secretary of University Court, The University, Glasgow (August 18)

Research Assistants (2) (with an honours degree in zoology), one to work on the aspects of respiratory physiology of vertebrates, and the other to study the ecology and systematics of mammals inhabiting small islands—The Secretary and Registrar, The University, Southampton (August 18)

Administrative Assistant (with appropriate scientific qualifications and at least a working knowledge of French), to be primarily concerned with the work of the British National Committees on Space Research and Co-operation in Geophysics—The Executive Secretary, The Royal Society, Burlington House, Piccadilly, London W 1 (August 20)

Demonstrator in Biology—The Registrar, The University, Keele, Staffs (August 21)

Lecturer or Assistant Lecturer (with a degree in veterinary medicine or physiology) in the Department of Physiology—The Secretary, Royal Veterinary College, Royal College Street, London, N W 1 (August 25)

Senior Lecturer or Lecturer in Mathematics at Newcastle University College, University of New South Wales—The Agent-General for New South Wales, 56/57 Strand, London, W C 2, and Appointments Section, University of New South Wales, Box 1, Post Office, Kensington, N S W , Australia (August 30)

Lecturer in Zoology at Victoria University of Wellington, New Zealand—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 (New Zealand and London, August 31)

Senior Lecturer (with a degree in the social sciences and experience in education) in Sociology of Education—The Secretary, University of London Institute of Education, Malet Street, London, W C 1 (August 31)

Demonstrator in Biology—The Registrar, The University, Keele, Staffordshire (September 1)

Head (honours graduate, preferably under 40, with suitable practical experience) of the Meat Section, to take charge of a division engaged in research related to the manufacturing aspects of meat and other animal products—The Secretary, The British Food Manufacturing Industries Research Association, Randalls Road, Leatherhead, Surrey (September 1)

Senior Lecturer in Hæmatology in the Department of Pathology, University College, Ibadan, Nigeria—The Secretary, Senate Committee on Colleges Overseas in Special Relation, Senate House, University of London, London, W C 1 (September 3)

Research Student in Geography—The Registrar, The University, Hull (September 7)

Senior Lecturer or Lecturer (preferably with an interest in either insect physiology or insects of medical importance) in Zoology at the Australian National University—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 (Australia and London, September 10)

Lecturer (with an honours degree in zoology) in Zoology at the University of Canterbury, New Zealand—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 (New Zealand and London September 15)

Reader in Cell Structure in the Department of Agriculture, Waite Agricultural Research Institute, University of Adelaide—The Registrar, University of Adelaide, Adelaide, South Australia (September 15)

Lecturers (3) in Civil Engineering at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 (Australia and London, September 17)

Senior Lecturer or Lecturer in Inorganic Chemistry tenable at either the Pietermaritzburg or the Durban centre of the University of Natal, South Africa—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 (South Africa and London, September 21)

Lecturer (with a degree in biochemistry, organic chemistry, physiology or pharmacology) in Biochemistry—The Secretary and Registrar, The University, Southampton (September 22)

University Demonstrator in Biochemistry—Dr J W Millen, Secretary of the Appointments Committee of the Faculty of Biology "B", Department of Anatomy, Downing Street, Cambridge (October 1)

Chair of Education—The Secretary and Registrar, The University, Southampton (October 27)

Chair of Psychology, Chair of Botany, Chair of Physiological Chemistry, Chair of Geophysics, Dean of the Faculty of Medicine, Senior Lecturer or Lecturer in Chemical Engineering at the University of the Witwatersrand, Johannesburg, South Africa—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1

Head (honours graduate in mathematics, with experience in the application of statistics to the planning and interpretation of biological experiments and to the general statistical problems arising in agricultural research, particularly with animals) of the Statistics Section—The Secretary, National Institute for Research in Dairying (University of Reading), Shinfield, Reading, quoting Ref 62/5

Hospital Physicist (with a B Sc first- or second-class honours in physics) at the Ahmet Andicen Cancer Hospital, Ankara, to take charge of the Radio Isotope Department—The Director of Recruitment, Department of Technical Co-operation, 3 Sanctuary Buildings, Great Smith Street, London, S W 1, quoting Ref RC 205/151/03

Lecturer (with a degree or diploma in technology in mathematics, physics or electrical engineering, practical experience in the appropriate field, and a special interest in electrical engineering) in Mathematics—The Secretary and Registrar, Bristol College of Science and Technology, Ashley Down, Bristol 7, quoting Ref CST 62/46

Postdoctoral Fellow, for research with Dr H C Clark, on the chemistry or organometallic compounds containing fluorine—Prof. C A McDowell, Department of Chemistry, University of British Columbia, Vancouver, B C , Canada

Senior Scientific Officer and a Scientific Officer (with at least a good honours degree or equivalent) in the Scientific Branch of the Public Health Department, for a wide variety of interesting work on research, development and scientific control—Medical Officer of Health (D 1/c/1759/7), London County Council, County Hall, London, S E 1

Tutorial Research Student in Botany—The Principal, Royal Holloway College (University of London), Englefield Green, Surrey

Variety of Sampling Systems Adds to Versatility of
F&M GAS CHROMATOGRAPHY EQUIPMENT

F & M offers a complete line of sampling accessories to permit the analysis of many different materials For gaseous samples, the Model GV-11 Gas Sampling Valve provides a convenient method of introducing reproducible samples into the chromatograph

The Model SI-4 Solid Sample Injector allows the chromatographic analysis of any solid that will vaporize when heated The Model SI-4 can be used to characterize polymers, follow chemical reactions and do kinetic studies It is also useful for introducing hard to handle liquid samples

A complete line of Hamilton Microliter Syringes is available for injecting precise liquid samples

Among the gas chromatography instruments available from F & M Scientific are the Model 500 with a thermal conductivity detector which features temperature programmed operation from ambient to 500°C The Model 1609 Flame Ionization Attachment extends the range of the Model 500 to this sensitive detection system

European customers are now being served by our European Subsidiary, F & M Scientific Europa, N V For additional information on gas chromatographs and sampling accessories contact International Department, F & M Scientific, Avondale, Pa , Phone 215 COlony 8-2281.

£500 A YEAR TAX FREE FOR YOUR FAMILY

The Equitable offers you a special plan to protect your family's future at the lowest possible cost Should you die within a period of 20 years your dependants will receive £500 a year tax free for the balance of the period

You only pay premiums for 15 years and if you are 29 now the cost is as little as £18 5 0 a year—about 7/- a week The premiums for larger benefits are in proportion

The Equitable offers attractive terms because it has no shareholders to take any part of the profits and pays no commission for the introduction of business.

APPOINTMENTS VACANT

KENT COUNTY COUNCIL
KENT EDUCATION COMMITTEE
NORTH-WEST KENT COLLEGE OF TECHNOLOGY
SCIENCE DEPARTMENT

1 Full-time Assistant Lecturer (Grade B) required for January (or sooner) to teach Chemistry to "A" and "O" level G C E standard and subsidiary physics or biology or mathematics General degree suitable Industrial experience an advantage

2 Full-time Assistant Lecturer (Grade B) required for January (or sooner) to teach Biology to "O" level G C E and zoology and botany to "A" level Ability to teach an ancillary subject an added advantage

Salary for both appointments on scale £770 to £1,350 per annum

Further particulars and application forms obtainable from the Principal at the College, Miskin Road, Dartford, Kent

NATIONAL INSTITUTE FOR RESEARCH IN DAIRYING
(UNIVERSITY OF READING)

Applications are invited for the post of Scientific Officer (male) in the Feeding and Metabolism Department, to carry out research on the nutrition and management of dairy cattle and in particular calves Applicants must have an honours degree in agriculture or agricultural chemistry and preference will be given to applicants with postgraduate training in research methods, who have had experience of experimental work with young cattle

Applications, enclosing the names of three referees, should be made to the Secretary, N I R D, Shinfield, Reading, before August 20, 1962 Quoting ref 62/10

UNIVERSITY COLLEGE OF NORTH WALES
BANGOR
MARINE SCIENCE LABORATORIES

Applications are invited for a post of Research Assistant to join a team studying the occurrence and isolation of physiologically active substances in marine invertebrates The post is most suitable for a zoologist who wishes to obtain experience of biochemical techniques and will provide some scope for original work The post is for a period of three years at a salary of £600 with F S S U benefits

Applications, with the names and addresses of two referees, should be sent to the Registrar University College of North Wales, Bangor, to reach him by September 1, 1962

COMMONWEALTH AGRICULTURAL Bureaux Applications are invited for the post of Scientific Information Officer at the Commonwealth Bureau of Plant Breeding and Genetics, Cambridge Work includes the abstracting and reviewing of biological literature Applicants should possess a biological degree, the ability to write correct English and preferably some knowledge of foreign languages Salary, £738 to £1,872 Starting salary according to age, qualifications and experience Increments up to two years granted for completed years of compulsory National Service and two further increments after two years' satisfactory service for applicants aged 32 or under at date of appointment Provision for superannuation —Applications, stating age, qualifications and other particulars and names of referees (work and character), should be submitted by September 8, 1962 to the Director of the Bureau, School of Agriculture, Cambridge

---

AUSTRALIA
COMMONWEALTH SCIENTIFIC AND INDUSTRIAL RESEARCH ORGANIZATION
SCIENTIFIC COMPUTING RESEARCH LABORATORY
SENIOR RESEARCH OFFICER
or
PRINCIPAL RESEARCH OFFICER

The Commonwealth Scientific and Industrial Research Organization is planning to establish a scientific computing network consisting of a number of small computers, placed in various locations, to operate in association with a powerfully equipped central computing research laboratory which will be located in Canberra, A C T The network will serve the expanding computing requirements of the Organization and other Commonwealth Departments, Agencies, and research bodies, including universities

The Organization is already seeking an Officer-in-Charge for the Laboratory and it plans also to recruit a few other key staff It is not likely that the computing centre will be in full operation in less than about two years, but it is desired to proceed with the appointment of a small number of highly qualified people Pending the availability of the computing centre, any such officers appointed will be able to become familiar with the scientific interests of the various Divisions of C S I R O and will be able to study methods whereby a wide range of physical and biological research programmes can be handled most effectively by the large computer which will be installed

It is possible that one appointee might spend a year or two in Melbourne, Victoria, largely with the Chemical Research Laboratories , another might be attached initially to the National Standards Laboratory in Sydney, N S W , while another might take up duty initially with one of the biological research groups

Salary Dependent upon qualifications and experience within the ranges

£A 2,426 to £A 2,751 per annum or £A 3,011 to £A 3,531 per annum

Fares paid for the appointee and his dependent family Further details of conditions supplied on application to

Mr P F Butler, Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W C 2,
to whom applications (quoting Appointment No 900/2) should be addressed by September 15, 1962

BDH

Junior Biochemist
for
CHEMICAL RESEARCH DEPARTMENT

for interesting work on such topics as steroid and drug metabolism, proteins/polypeptides, etc

Applications, with full details to

Personnel Manager, Ref HAC/VP,
THE BRITISH DRUG HOUSES LTD ,
Graham Street, London, N 1

UNIVERSITY OF KEELE

Applications are invited for the post of Demonstrator in Biology Remuneration £700 per annum The appointment which is tenable from September 1, 1962, is for one year in the first instance

Applications should reach the Registrar, the University, Keele, Staffs, from whom further particulars and application forms may be obtained, not later than August 21, 1962

McMASTER UNIVERSITY
DEPARTMENT OF CHEMISTRY

Applications are invited for a Post-doctoral Fellowship in Physical-Organic Chemistry for work on kinetic isotope effect studies in relation to reaction mechanism The annual stipend for full-time research is $4,000 for a single and $5 000 for a married Fellow With light teaching duties the stipend may reach $6,000 Travel allowance is provided

Applications should be sent to Professor A N Bourns, McMaster University, Hamilton, Ontario, Canada

UNIVERSITY OF OTAGO
DUNEDIN, NEW ZEALAND
LECTURER IN ANTHROPOLOGY

Applications are invited for this position is intended that the successful applicant wi specialize in Social Anthropology Salary, £1,2 by £75 to £1,700 per annum

Further particulars are available from the Se retary, Association of Universities of the Britis Commonwealth (Branch Office), Marlboroug House, Pall Mall, London, S W 1, or from th Registrar, University of Otago, Dunedin A plications close in London and New Zealand September 15, 1962

UNIVERSITY OF OTTAWA
OTTAWA, CANADA

Positions of Research Assistant and Assista or Associate Professor in Pharmacology wit training in Pharmacology, Physiology or Biochem istry Salary $5,500 and $9,500 respectively

Applications to Professor M F Murnaghan above address

DU PONT
REG U S PAT OFF

NEOPRENE
SYNTHETIC RUBBER

Due to planned expansion and the development of an Isocyanate plant on the site, we require the following appropriately qualified technical personnel

Permanent Positions

Free Life Insurance

Contributory Pension Plan

RESEARCH CHEMISTS

Preferred qualification Ph D degree Experience in research and plant trouble shooting would be advantageous, but not an essential requirement

CHEMISTS

2–6 years chemical plant experience Graduates preferred.

The Plant is in Northern Ireland about five miles from the City of Londonderry and is on the banks of Lough Foyle It is ideally situated for those who would enjoy a combination of town and country life and who have interests in sports

House purchase facilities available

Removal expenses paid

Opportunities for Advancement

If you have the appropriate qualifications write for an application form, state age and give brief details of experience to

The Personal Assistant to the Managing Director,

DU PONT COMPANY (UNITED KINGDOM) LTD., 76 JERMYN ST., LONDON, S.W.1

AUSTRALIAN NATIONAL UNIVERSITY
INSTITUTE OF ADVANCED STUDIES
JOHN CURTIN SCHOOL OF MEDICAL RESEARCH
RESEARCH FELLOWSHIP

Applications are invited from Organic Chemists with experience in the synthesis of pyrimidines and pteridines, and the measurement of their ionization constants and spectra The successful applicant will work at the outset with Dr D J Brown on the chemistry of such heterocyclic substances The salary range for Research Fellows is £A 1,656 to £A 2,450 per annum, and appointment is made for three years, with possible extension to the maximum of five years Superannuation is on the F S S U pattern Reasonable travel expenses are paid and assistance with housing is provided

Further particulars should be obtained from the Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 Applications close in Australia and London on August 31, 1962

UNIVERSITY OF MANCHESTER

Applications are invited for the post of Assistant Lecturer in the Department of Metallurgy of the Faculty of Science, in the field of Physical Metallurgy Candidates should be graduates in physical metallurgy or solid state physics, preferably with interest or research experience in the field of deformation studies or magnetic properties An extensive research programme in the field of internal friction has been pursued in the Department for many years, and development of interest in magnetic properties is considered desirable Duties to commence October 1, 1962, or as soon as possible thereafter Salary scale £900 to £1,050 per annum, with membership of the F S S U and children's allowance scheme

Applications should be sent not later than August 31, 1962, to the Registrar, the University, Manchester 13, from whom further particulars and forms of application may be obtained

---

UNIVERSITY OF CAPE TOWN
LECTURER IN ZOOLOGY

Applications are invited for the post of Lecturer in Zoology tenable from January 1, 1963 Experience in invertebrate teaching to B Sc honours level is highly desirable Good facilities for marine biological research are available The appointment will be made on the salary scale R 2,680 by R 120 to R 3,520 (£1,340 by £60 to £1,760) per annum in accordance with qualifications and experience

Two copies of the application and testimonials should reach the Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 (from whom memoranda giving the general conditions of service including transport expenses on appointment and information on the work of the department may be obtained) not later than September 30, 1962 An additional copy should be sent direct by airmail to the Registrar, University of Cape Town, Private Bag, Rondebosch, Cape Town, South Africa, by the same date

Applicants should state their age, qualifications, experience, research work and publications and give the names of two referees whom the University may consult

The University reserves the right to appoint a person other than one of the applicants or else to make no appointment

---

UNIVERSITY OF SOUTHAMPTON

Applications are invited for Research Fellowship in field of Biological Free Radical Study from recent or prospective Ph D graduates or persons with equivalent research experience in biochemistry, physiology, biophysics or allied subjects The appointment is renewable annually for a period of three years Salary £800 per annum, plus F S S U, commencing October 1, 1962, or earlier by arrangement Opportunity for limited participation in the teaching of the department if desired

Applications, with full details of research experience and publications together with the names of three referees should be sent to the Secretary and Registrar, the University, Southampton, not later than August 25, 1962

GOVERNMENT OF WESTERN CAMEROON
LAND UTILIZATION OFFICER

To advise on land utilization generally To work out future boundaries between grazing and farming land in the Bamenda area, which is at present being surveyed by a team from F A O To train a Cameroonian to take over the work Candidates, between 25 to 50, must have a degree in agriculture/botany/geography or geology with at least two years experience in land utilization work, preferably in Africa A knowledge of written and spoken French would be an advantage Appointment on contract for one tour of 12 to 24 months Salary £2,184 per annum, plus a gratuity of £37 10s per quarter payable at the successful completion of the contract Free passages Accommodation available at a rental of 8½ per cent of salary Free medical and dental facilities Generous home leave

Apply, stating full name and giving brief particulars of qualifications and experience, to Director of Recruitment, Department of Technical Co-operation, Great Smith Street, London S W 1 Quote RC 213/23/01/C1

WESTERN REGIONAL HOSPITAL BOARD
DEPUTY REGIONAL PHYSICIST

Applications are invited for the post of Deputy Regional Physicist The person appointed will be responsible to the Regional Physicist for the day-to-day conduct of an active laboratory with a staff of 65, including 40 science graduates Candidates should have high academic qualifications in physics, with experience in one or more of the following fields (a) Research and teaching in a University Department, (b) responsibility for the work of a scientific team in an industrial establishment, a government laboratory or a hospital, (c) application of scientific methods and ideas to problems arising in clinical research Salary scale £2,250 to £2,600 with superannuation benefits Six weeks' annual leave

Applications should be sent before August 20, 1962, to the Secretary, Western Regional Hospital Board, 351 Sauchiehall Street, Glasgow, C 2

DCL

RESEARCH CHEMISTS

The Distillers Company Limited is a major producer of organic chemicals and plastics for industry Its activities in these rapidly expanding fields have created several openings as under for Research Chemists at the Research Department, Epsom, Surrey, where the Company's fundamental and longer term research is undertaken

Petroleum Chemicals (Ref 269N)

Physical-organic chemists are required to undertake research work on the development of chemicals from petroleum

Plastics (Ref 270N)

Physical chemists are wanted for research work in the field of polymers involving the study of polymerisation techniques and the measurement of the molecular weights of high polymers

Reaction Kinetics (Ref 275N)

A vacancy exists for a physical chemist to join a team carrying out fundamental research in physical chemistry mainly concerned with the mechanisms of organic chemical reactions He will study either heterogeneous catalysis or liquid phase oxidation of hydrocarbons

Gas Chromatography (Ref 271N)

A research chemist is wanted to examine the uses of gas chromatography particularly in connection with analytical problems arising from laboratory research work and full scale production of petroleum chemicals and plastics The work will involve theoretical aspects including thermodynamics A research qualification is not essential for this post

Candidates, aged preferably not over 35, must hold a good honours degree in chemistry or an equivalent qualification, and a research degree is desirable Applications are invited from men returning from research fellowships abroad, from others with industrial experience as well as from those who have completed, or will shortly complete, their postgraduate degrees

These positions can be starting points of rewarding careers either in the Research Department itself or elsewhere in the Company Assistance can be given to married men towards house purchase and removal expenses

Please write, quoting the appropriate Reference No, to

STAFF MANAGER,
THE DISTILLERS COMPANY LIMITED,
21–22 BOLTON STREET, LONDON, W1

The Cementation Company

is seeking

A PHYSICIST

with an M Sc, or Ph D degree whose main field of interest would be concerned with the molecular properties leading to strength of solids and the strength and mobility of composite solid fluid systems We look for a man of originality who is prepared to turn his interests to the more subtle aspects of a wide variety of subjects

A PHYSICIST OR APPLIED PHYSICIST

to work on problems concerned with the application of physics and instrumental techniques to fluid processes involving flow, mixing, filtration and separation

Applicants should have a degree in Physics or be Graduates of the Institute of Physics

These are responsible posts in the Physics section of the Company's new Research Laboratories situated in pleasant country south of Rickmansworth.

Write with details of career to Head of Research

Research Laboratories, Maple Cross, Rickmansworth, Herts

DSIR

Laboratory of the Government Chemist London, requires Scientific Officer/Senior Scientific Officer for work on qualitative and quantitative analyses of wide variety of organic and inorganic materials, development of new analytical methods and improvement of equipment Encouragement will be given to publication of original work The officer will work in division dealing also with gas-liquid chromatography, infra-red absorption, ultra-violet and visible emission and atomic absorption spectroscopy, thus affording wide ancillary interests Qualifications First- or second-class honours degree in chemistry Sound knowledge of physical methods of chemical analysis particularly in field of X-ray diffraction and X-ray fluorescence analysis essential Salaries Senior Scientific Officer (minimum age 26 and at least three years' postgraduate experience), £1,456 to £1,785, Scientific Officer, £823 to £1,331

Application forms from Government Chemist, 13 Clement's Inn Passage, Strand, London, W C 2

UNIVERSITY OF EDINBURGH

DEPARTMENT OF CHEMISTRY LECTURESHIP

Applications are invited for the post of Lecturer in Theoretical Chemistry in the above Department Salary scale £1,150 by £50 to £1,350 bar £1,400 by £50 to £1,500 by £75 to £1,950 per annum, with placement according to qualifications and experience, and with superannuation benefit and family allowance where applicable The successful candidate will be expected to take up duty on October 1, 1962

Further particulars may be obtained from the undersigned, with whom applications (six copies), giving the names of two referees, should be lodged not later than August 13, 1962

CHARLES H STEWART,
Secretary to the University.

UNIVERSITY OF GLASGOW

LECTURER (BIOCHEMIST) IN DEPARTMENT OF MEDICINE AT WESTERN INFIRMARY

Applications are invited for the post of Lecturer (Biochemist) in the Department of Medicine at the Western Infirmary Salary scale £1,150 by £100 to £1,950 per annum for those medically qualified, £1,150 by £50 to £1,500 by £75 to £1,950 per annum for those not medically qualified Initial salary according to experience and qualifications F S S U and family allowance benefits

Applications (eight copies), should be lodged, not later than August 18, 1962, with the undersigned, from whom further particulars may be obtained

ROBT T HUTCHESON,
Secretary of University Court.

THE NATIONAL PHYSICAL LABORATORY (D S I R), Teddington, Middlesex, requires Scientific Officers/Senior Scientific Officers and Assistant Experimental Officers/Experimental Officers for a small research group Developing Components and Circuits for Advanced Digital Computers Duties (1) Research and development on cryotrons, their detailed operation, their structure, and the method of making and connecting them (2) Developing the circuit design of new components in digital computer applications, with emphasis on the cryotron, involving the study of layout and interconnections and instrumentation assistance to the making and testing of components (3) (For Scientific Officers/Senior Scientific Officers) Logical design requiring knowledge of current digital computers to study the effects of the advent of new components and their circuits In particular, logical problems arising from interconnections will be studied As the project develops this part will be expanded, and will include studies of automatic design, layout, and manufacturing techniques Qualifications (a) Scientific Officer or Senior Scientific Officer first- or second-class honours degree or equivalent, with at least three years' postgraduate experience for Senior Scientific Officer (b) Assistant Experimental Officer/Experimental Officer Higher National Certificate or equivalent in subjects including electronics Salary scales Scientific Officer, £808 to £1,321 Senior Scientific Officer, £1,446 to £1,780, Assistant Experimental Officer £706 (age 22) to £873 (age 26 or over) to £1,067, Experimental Officer, £1,175 to £1,439 Application form from the Director at above address, quoting 74 VY for Scientific Officer/Senior Scientific Officer posts and 74 E B for Experimental Officer/Assistant Experimental Officer posts Closing date September 10, 1962

25.9.62 Pure Chemistry Library. SCIENCE COLLEGE 92, Upper Circular Road. CALCUTTA.

GOVERNMENT ORGANIZATION OF SCIENCE IN BRITAIN

THE rather rambling debate on science and industry in the House of Commons on July 12 covered many aspects, including the Zuckerman Report on the management and control of research and development, the Trend Committee on the Government organization for the promotion of scientific research in the civil field, the latest report of the Department of Scientific and Industrial Research, the report on industrial research in manufacturing industry issued by the Federation of British Industries, Prof. R. Aron's recent paper on the education of the citizen in industrial society in *Daedalus*, as well as that of Sir Eric Ashby in the same issue, all of which have been discussed recently in *Nature**.

In opening the debate, Mr. G. R. Mitchison sought to obtain more information on the activities of the Minister for Science and of his Parliamentary Secretary or at least some precise definition of the functions of the Ministry. If he scarcely succeeded in this, he drew from Sir Edward Boyle, then Financial Secretary to the Treasury, who concluded for the Government, the announcement that a grant of about £250,000 was being offered to the University of London by the Department of Scientific and Industrial Research to provide a low-power reactor for research and training. This would be a 100-kW *Consort* made by the General Electric Co., Ltd., and would be operated at Silwood Park by the Imperial College of Science and Technology primarily on behalf of the University. However, it would also be available for use by other research organizations in the London area. Early in the debate, Mr. D. Freeth had referred to the establishment by the Department of Scientific and Industrial Research, at the request of the Minister for Science, of the Committee under the chairmanship of Mr. G. B. R. Fielden to consider the present standing of mechanical engineering design and to recommend any changes which are likely to result in improved engineering design of British products, including, in particular, changes in education and training.

Sir Edward Boyle in this speech gave little fresh information about Government policy in general. Commenting on the importance of innovation in industry, he observed that this applied also to commerce, as well as to the Government's own administrative arrangements, though he stressed the value of the flexibility in existing arrangements. Regarding the universities, he merely referred to the research grants of the Department of Scientific and Industrial Research, to the expansion of the colleges of advanced technology, which would cost at least £160 million in five years time, and to the decisions which would have to be taken when the report of the Robbins Committee became available. He also said that the Government intended to do what it could to ensure that more opportunities of administrative work were available to scientists.

Sir Edward also referred to the report of the *ad hoc* Committee of the Royal Society on biological research and agreed with what Mr. Mitchison had remarked as to the exciting vistas in biology which seem to have been opened up. The Minister for Science had received a copy of the report and was seeking advice on it from the Advisory Council on Scientific Policy, the report was also receiving detailed consideration from the Research Councils which supported biological research. He did not, however, comment on the concrete suggestions which Mr. Austen Albu made later in the debate.

Mr. Albu, who directed attention to Prof. R. Aron's paper and deprecated excessive distinction between pure and applied science, had urged that the research associations should be more concerned with basic research and suggested that they needed a stable and more generous grant from the Government. Furthermore, they should be allowed to undertake sponsored research on the condition that the director of the association was satisfied that the proposed research fitted in with his general programme. He thought that the use of development contracts was of increasing importance, and that the Department of Scientific and Industrial Research should receive a block grant on the lines similar to the University Grants Committee and other Research Councils. He also suggested that the Minister for Science should be directly responsible for all major scientific expenditure, including that of the Atomic Energy Authority, the three existing Research Councils, the Nature Conservancy, and a new 'technological development council' which he proposed for identifying subjects for development and research contracts.

Such a council, Mr. Albu envisaged, should be comprised mostly of engineers with a good scientific background, this, he thought, might eliminate the frustration which at present arose under the present arrangements when projects were submitted individually to the Treasury. He also suggested a research council to deal with fundamental research in the universities and another research council for the social sciences. He would make the Minister for Science responsible for research development as well as some sections of the Board of Trade, and suggested also a joint committee of the Ministry for Science and the research departments of the Services and the Ministry of Aviation. In common with other speakers in the debate, he was concerned with the use of scientists as administrators and the training required with administrative or managerial posts. He advocated a permanent staff for the Minister at least of scientists and technologists working half-time or perhaps full-time for three or four years, but not more.

---

* See, for example, *Nature*, **193**, 710, **194**, 119, 1105, **195**, 1 (1962)

It is difficult to discuss seriously Mr Albu's proposals without further details, and Mr Albu himself said nothing to suggest what advantages they would offer over the existing set-up if those arrangements were effectively used—if, for example, the link between the Advisory Council on Scientific Policy and the Defence Research Policy Committee were effectively restored In view of the inquiry into the Government organization which is already in progress, it could scarcely have been expected that the Government spokesman would comment on such proposals, however, the debate should at least expedite the inquiry and perhaps induce the Minister to deal with the dilatoriness which has held up for more than a year the promised report on the support of university research by the Department of Scientific and Industrial Research Possibly the inquiry into the research associations could also be included in some constructive statement without excessive delay

Two other features of this debate call for comment First, as in the debate on the National Productivity Year in the House of Lords on the same day, the importance of the quality of industrial management was repeatedly stressed Mr W Stones and Mr J H Osborn suggested that the science of management was one of the most important disciplines to-day, the need for industrial managers to be appropriately qualified if effective use was to be made of either the results of research or Britain's trained manpower was repeatedly emphasized In this connexion, it may be noted that earlier in the day the then Minister of Education, Sir David Eccles, had been asked to establish a central library of publications on business and management education He had replied that he thought it would be better to develop the existing libraries of the British Institute of Management and other bodies which were already well stocked Sir David also referred to the libraries of the colleges of advanced technology, and welcomed the conference on business and management education which the British Institute of Management was planning early next year

While in the House of Commons speakers were concerned with management in respect of the utilization of scientific and technological advance, in the House of Lords the main emphasis was on the handling of British manpower resources and on the human problems of industry However, Lord Marks of Broughton pointed out that Britain could only be fully competitive if there was a concentrated effort at factory-level to exploit the wealth of new and efficient techniques which science and technology were making available Increased productive efficiency and the understanding of human relations must be regarded as a constant challenge which demanded continuous study, education and application Lord Crook, in opening the debate, had stressed the vital importance of the quality of management and the need for a forward-looking approach to all management problems The long-term effects of managerial decisions were too often ignored, and the policy of management in recruitment was of paramount importance

Lord Crook recognized that scientific and technological developments were such that firms must increasingly look to the universities and colleges of technology for recruitment of their future managers, and Lord Baillieu pointed out that apart from technical qualifications, certain qualities of mind and character were essential if the opportunities before us were to be attacked with understanding and responsibility and genuine leadership provided Lord Shackleton urged the need for a more critical approach to problems of management, suggesting in fact much the same approach as the Zuckerman Committee has applied to research and development in Government establishments and which the Trend Committee is now applying to the arrangements for civil research under Government auspices This was welcomed by Earl Waldegrave in replying for the Government, who entirely agreed that the most important factor in the success of the drive for natural efficiency was the solution of the human problems and misunderstandings which still arose The National Productivity Year, which opens in London in November, aims at removing these misunderstandings on both sides of industry

If this debate was a fitting counterpart to the debate in the House of Commons in directing attention to the human factors which must be handled wisely if full advantage is to be taken of scientific and technical advance in industry, a second feature of the debate in the Commons deserves notice Mr Mitchison had pointed out how easily questions of scientific policy involved political decisions, and reminded the House that the allocation of national resources as between biology and nuclear physics, for example, was really a political decision He rather confused the issue both in his reference to the Trend Committee and in that to the Advisory Council of Scientific Policy in this connexion, but the position was correctly stated by the Parliamentary Secretary for Science, Mr Denzil Freeth

Mr Freeth pointed out that the Advisory Council on Scientific Policy were the main advisers of the Minister for Science on general scientific policy They could represent, for example, the form which any space research activity by Britain should take and the size of that effort The decision, however, whether Britain should have a space research programme, the form it should take and its size, was a political decision which the Government alone could take Scientific advisers can only indicate what is required for any such effort to be effective and point out what are the implications of any particular effort

What matters is that the organization for giving scientific advice should ensure that it draws on the best available advisers, that it is representative and takes full account of all the conflicting factors The organization must be such as to command the confidence of the scientists and technologists themselves Above all, it must satisfy them that their time is not being wasted, and that their advice is presented effectively at the level at which political decisions are taken to those who are competent to evaluate the scientific and technical factors along with the other elements that must be taken into account in reaching a decision There are obligations here for the Government as well as the scientist—questions of communication—and it is entirely appropriate that the adequacy of the arrangements should be considered by such a body as the Trend Committee They are not as Mr Mitchison suggested, being asked to take political decisions, but rather to report on the adequacy of the arrangements for ensuring that the scientific and technical aspects of a problem are correctly presented to the Government as a basis for decision

What, of course, could be observed is that some such inquiry might well have been instituted much earlier and also that although the Zuckerman Report has been accepted as laying down a standard of practice, its recommendations appear to be put into practice very leisurely It is to be hoped that further delay will not result from the recent reconstruction of the Government, and since the Minister for Science and his Parliamentary Secretary have retained their offices, they should at least do their utmost to ensure that delay is kept to a minimum Moreover, there is a large field in which it would seem that the final responsibility rests with the Minister for Science and that he alone is to be held responsible for any delay or failure to correct recognized weaknesses The debate in the House of Commons at least affords a pointer to some prodding that he might institute forthwith

NUCLEAR POWER FOR INDUSTRIAL PURPOSES

Nuclear Power Today and Tomorrow

By Kenneth Jay Pp viii + 270 + 16 plates (London Methuen and Co , Ltd , 1961) 25s net

IT is just twenty years since Enrico Fermi's atomic pile went into action in Chicago and in that twenty years unprecedented effort, whether measured in money or in number and quality of scientific investigators, has been spent in the development of large-scale installations for producing from nuclear energy a supply of electrical power on the scale required by modern industry and modern domestic needs A large number of technical books have appeared in recent years dealing both with the general range and with particular aspects of the new subject of nuclear engineering Hitherto, however, there has been lacking a book, accessible to readers with no particular knowledge of nuclear matters or of engineering, which gives an accurate and authoritative account of what has been accomplished in the field as a whole and what may be reasonably anticipated This need is now supplied

The book before us makes clear, in the first place, the scientific foundations of the subject, in particular the reaction with appropriate nuclei of the neutron "This incredibly tiny, electrically uncharged, particle is in fact the key to the new age", as the author says He develops the theme with a skill and happy phraseology that makes the subject simple, explaining such matters as the difference between thermal and fast reactors, the types of nuclear fuel, uranium isotopes and plutonium, that can be used, and the different possible processes involving them Having pointed out that only nuclear fission, and not nuclear fusion, is in question in these industrial applications, he calls the type of nuclei which can be split "fissile fuel", in contrast to coal, which is fossil fuel

The all-important question of cost, especially capital cost, of nuclear power is considered in comparison with that of ordinary electrical power generation The subject is a complicated one, but the various factors which have to be borne in mind are set out with admirable clarity The author then proceeds to give a survey of the nuclear power programmes of the countries most active in the field, namely, the United Kingdom, the United States, the U S S R , Canada, France and Federal Germany The existence at Winfrith in Dorsetshire of an installation, supported by international collaboration, for developing a particular type of gas-cooled reactor will come as news to many

The general functions of moderators, coolants and pressure vessels having been described, the different classes of reactor systems, with their peculiar advantages and difficulties and the circumstances which determine them, are discussed in some detail—the gas-cooled graphite-moderated reactors, hydrogen-moderated systems, fast reactors, the sodium-graphite systems and liquid-fuelled reactors The way in which the essentials are selected bears witness to the width of the author's knowledge it requires much less understanding to give every detail than to set down just what is material The last chapter deals with general questions involved in developing a reactor, such matters as radiation damage to fuel and metals, safety and other outstanding problems being discussed

The diagrams representing in outline the various processes are excellently designed and executed, there are a number of photographic plates showing reactors as a whole and details of construction which bring home the nature of the installations, there is a glossary of technical terms in which the reader will find at once what is meant in the reactor world by for example, breeding An additional recommendation is that the price is very moderate The author is to be congratulated on outstanding success in a very difficult task, having provided an account of the complex subject which is at the same time comprehensive and comprehensible

E N DA C ANDRADE

BIOPHYSICS AND MOLECULAR BIOLOGY

Molecular Biophysics

By Richard B Setlow and Ernest C Pollard (Addison-Wesley Series in the Life Sciences) Pp xiii + 545 (London Pergamon Press, 1962) 84s net

BIOPHYSICS has been defined as the application of the concepts and techniques of physics to biological problems, often with the instinctive approach of a physicist who believes that thought, inspiration and experiment can pick out the essential elements underlying apparently complex phenomena and may often provide satisfyingly simple ways of accounting for them Molecular biology is concerned with the basic properties and interactions of biologically important molecules, studied by whatever approach—biophysical, biochemical, genetical—seems most opportune, and this large and ambitious book was designed by its authors to cover the approach from biophysics

The level of the test is intended to be suitable for advanced undergraduate or first-year graduate students in the United States, it has been written with an eye to the increasing number of biophysics courses now being given, and is in fact based on such a course at Yale University The book contains a large amount of valuable information summarized in one place, though it would perhaps be most useful as a collection of essays to serve as introductory background reading for topics on which one wanted information, rather than a text-book to define an area of study There are fifteen chapters, including (after some introductory discussion) ones dealing with physical methods of determining the sizes and shapes of molecules (36 pp), X-ray analysis (43 pp), intra- and inter-molecular forces (33 pp), absorption spectroscopy (50 pp), enzymes (28 pp), action spectra (39 pp), ionizing radiation (74 pp), microscopes (33 pp), isotopic tracers (31 pp), muscle nerve and eye studies (41 pp), collision and diffusion in cells (33 pp), very well chosen recommendations for further reading are given at the end of each chapter These are all important and interesting topics in biophysics, though their relative importance in present-day molecular biology could perhaps not readily be deduced from the amount of space devoted to each, nor from the degrees of emphasis given in the text A diligent student who mastered the contents of this book might still emerge without having formed, from knowledge of the past history of the subject, a good sense of judgment of how best to set to work on some actual problem

The construction of the book "presupposes some knowledge of mathematics, physics, chemistry and biology beyond the elementary level", and "since most students will not fit into this category" it has been "designed so that students strong in at least two of these fields will have no difficulty in getting through the material" Now it is not easy to see how these three statements can all be true simultaneously and, indeed, they are not The physicist-chemist will not make much sense of the discussion on genetic linkage (incompletely explained) on p 36, nor of that on the recon, the muton, and the cistron, which follows, all too soon, on p 37 The chemist-biologist may, I imagine, be equally at sea in the derivation of the 'random-walk' expression on p 81, in the formulation of the general expression for the amplitude of scattered X-rays on p 129, or in the statement of Poisson's equation $\nabla^2 V = \rho/\varepsilon$ on p 177 These are failings which it is difficult to avoid in a book of practical size In cases of the latter type, of which there are many, it would often, though not always, be possible for a diligent non-physicist to extract some useful formula, table or graph, but these are not separated from the more specialized discussions in any way, nor is any indication given where sections might be omitted without the general understanding of the topic being impaired, and so it is likely to be heavy going in places However, the discussion of the more physical topics is competently done, and most of the information is there The more biological discussions are marred by the assumption of quite considerable prior knowledge, and by an excessive reluctance to say what things are important and basic, so that often the search for the underlying simplicities is obscured There are also some statements (for example, "The nuclear membrane" (presumably of all cells) "is seen" (in thin sections in the electron-microscope) "to be made up of a series of threads running criss-cross, about 10,000 Å long by 500 Å wide") which appear to be in error.

Thus, while the book could not be given an unqualified recommendation as a solitary text for incipient molecular biologists, there is much in it which could be read with advantage by people at a somewhat later stage H E Huxley

EUROPEAN UNIVERSITIES

Universities of Europe

By Anthony Kerr Pp 235 (London Bowes and Bowes (Publishers), Ltd., 1962) 25s net

The Democratic Intellect

Scotland and her Universities in the Nineteenth Century By Dr George Elder Davie (Edinburgh University Publications History, Philosophy, and Economics, No 12) Pp xx + 352 + 8 plates (Edinburgh The University Press, 1961 Distributed by Thomas Nelson and Sons, Ltd , 1961) 50s net

Mr KERR'S attempt to describe briefly university organization, studies and life throughout Europe is certainly bold and it succeeds in answering reasonably for the general reader the question, "What is a university ?" To that extent his book is a useful contribution to the present-day discussion on university expansion in Britain and on the place of universities in the community to-day His concluding chapter directs attention to some of the problems on which decisions must be taken when the Robbins Committee reports and about which it is important that public opinion should be well informed In this chapter, Mr Kerr expresses some personal opinions as to desirable changes, but it is by no means clear as to whom his book is primarily addressed, and in that respect it is not altogether realistic

The first eight chapters deal successively with the northern countries (including Iceland), the Soviet Union, Central Europe, the Benelux Union, France, the Iberian Peninsula, Italy and the Balkans with a separate chapter—the British Isles Some forty pages devoted to the British scene, with its voluminous literature are scarcely in balance with twenty pages for Norway, Sweden, Finland, Denmark and Iceland combined, with twenty on Central Europe and a dozen on Belgium and Holland, on all of which, for British readers, literature is scanty More serious is the almost entire absence of references To append an admirable address of Sir Keith Murray on the 'University Grants Committee' does not compensate for the absence of any select bibliography of authoritative works on the British universities Moreover, universities of all institutions are not to be considered apart from their past, and even the most competent first-hand account of present conditions needs, as background, some reference to previous studies Rashdall and Flexner have not been superseded, and to write of Germany without reference to Flexner, F Lilge's *The Abuse of Learning*, or especially the report of the Commission on University Reform in Germany, seriously weakens the claims of the book to the attention of the very readers to whom it should most appeal Moreover, the paucity of the literature strengthens the claim for some reference to the comparisons between universities presented at the second educational conference of the Association of University Professors and Lecturers of the Allied Countries in Great Britain Likewise, the dozen pages dealing with the Soviet Union should at least have been supported by reference to Mr A G Korol's book

Mr Kerr's painstaking current observations scarcely lift the book above the level of competent journalism, and in this it contrasts sharply with Dr Davie's scholarly but slightly astringent study of Scotland and her universities in the nineteenth century There is no popular appeal in this book and its title is slightly misleading Nevertheless, its exposition of a phase of Scottish history illustrates the nature of some of the interactions between universities and the society in which they function, and points to dangers which arise when academic independence is either infringed or abused It is a book for the student rather than for the general reader, though it has obvious messages for the present-day debate—if they are not perhaps altogether those which Mr J Grimond had in mind when he commended the book recently to Mr H Brooke in the House of Commons

R Brightman

SOCIAL BEHAVIOUR AMONG ANIMALS

Animals as Social Beings

By Prof Adolf Portmann Translated from the German by Oliver Coburn Pp 247 + 32 plates (London Hutchinson and Co (Publishers), Ltd, 1961) 30*s* net

THIS book is a translation of Prof Portmann's *Das Tier als soziales Wesen* and is concerned to present the "basic phenomena of social life" in animals, and the implications for the life of the individual and the group, including, in some cases, human groups It draws largely on the work over the past twenty-five years of those students of animal behaviour known as ethologists The book apparently developed from some lectures delivered to a non-scientific audience with the purpose of describing some of the advances in animal behaviour study It does not claim to be either comprehensive or authoritative (the author's own research has not been in this field), and it is a popularization in the best sense it selects many interesting facts to illustrate chosen themes, often quoting extensively from the original papers of the workers concerned, rendering them in a very readable context

But one's reservations come more to the fore when seeing how these facts are related together in his treatment of the whole field Prof Portmann has read widely in the literature of the subject, but he has a point of view probably untypical of most of the ethologists whose work he quotes, which colours much of the later parts of the book For example, he dislikes the conventional view of natural selection as the major agent of evolution It is of course true that social behaviour raises special evolutionary problems, as Darwin was well aware, but Prof Portmann gives it a marginal role and seems too ready to resort to other, as usual unspecified, agencies, he writes, for example, of "primordial darkness, which can yet be imagined as fraught with creative existence"

Quite apart from this criticism of the general approach, the reader should be warned that the ethological theories of instinct, etc, outlined in parts of the book are in a stage of vigorous metamorphosis, from which they will probably emerge with a very different look

Finally, Prof Portmann has been ill-served by his translator The original must have been extremely difficult to deal with, and perhaps for this reason the English version misses out a certain amount, but there are too many absurdities, for example, the dying act of the male sea-horse (instead of the final act of its courtship), a hierarchy of nerves (instead of a nervous hierarchy), while bees are said to have hindquarters and birds to brush their feathers

J M Cullen

PROGRESS IN PHYSIOLOGY

Annual Review of Physiology

Vol 24 Edited by Victor E Hall, in association with Frederick A Fuhrman and Arthur C Giese Pp v + 604 (Palo Alto, Calif Annual Reviews, Inc, 1962 Published in co-operation with the American Physiological Society) 7 dollars

"THE *Annual Review of Physiology* has selected its contributors because they can write good reviews" The editors of this volume begin their preface on this confident note They have good reason to be pleased with their choice of Prof Wallace O Fenn to write the introductory chapter Under the heading "Born Fifty Years Too Soon" he compares research conditions in physiology as they were a few decades ago and as they are to-day Physiologists and other biologists will enjoy reading and re-reading Prof Fenn's lively reminiscences and penetrating comments, based on his long experience of research in the United States

The editors have restricted the number of topics reviewed in this volume to 16, and this has meant that reviewers have been free to write readable, critical assessments of their subjects, rather than being virtually confined to the recording of card indexes of references Thus, the longest article, on kidney, water and electrolytes (G Giebisch), extends to 64 pages As usual, there are chapters on heart, respiration, digestion, reproduction and peripheral circulation This year's volume also covers growth and differentiation, temperature, cutaneous sensibility, the adenohypophysis and adrenal cortex, and blood volume regulation There are chapters on somatic functions of the nervous system, excitation and synaptic transmission, and on the physiological bases of memory The final two chapters will interest not only physiologists but also biologists in general They deal with the comparative endocrinology of the invertebrates (W G Van der Kloot), and with the effects of latitude on physiological properties of animal populations (F J Vernberg) These two chapters are full of interesting observations and experiments To select just one example, it has been shown that the queen bee secretes an unsaturated 10-carbon acid, 9-oxo-2-decenoic acid, which acts as a 'social' hormone towards the worker bees, preventing them from building new queen cells When this acid is no longer released in the hive, the ovaries of the workers begin to develop, and these bees then start to build cells for new queens

The general high quality of the articles in this volume justifies the editors' claim that they select people who can write good reviews

D C Harrison

EMPIRICISM AND LOGIC IN THE DISCOVERY OF NEW DRUGS*

By Prof. C. A. KEELE

Department of Pharmacology, Middlesex Hospital Medical School, London

THE word 'empiricism' in relation to medicine is defined variously in the *Oxford Dictionary* as "Practice founded upon experiment and observation, ignorant and unscientific practice, quackery". The original Empirics were Alexandrian Greeks of the third century B.C. who held that treatment of disease should be based on experience alone. They were opposed to the Dogmatists who based their treatment on theories, such as the humoral theory of disease. The Dogmatists would have disapproved of an Empiric as "One who in matters of science relies solely on observation and experiment" and one can perhaps see their influence in the debasement of the word to "One who practises physic or surgery without scientific knowledge, a quack, a charlatan". However, I still think that there is a real need for a word to describe "Practice founded upon experiment and observation only" and I make no apology for using the word 'empiricism' in its original sense. For me it is not a smear word, and if anyone wants to say that certain practices are irrational, unscientific or fraudulent, well, why not use these very words and leave 'empiricism' to its earlier meaning of trial, experiment and experience? All scientific observations are empirical and I shall discuss one example to show how even without theoretical principles it is possible to discover a new drug of great practical importance. 'Logic' is defined as "the science or art of reasoning as applied to some particular department of knowledge or investigation". The word 'drug' means "an original, simple medicinal substance, organic or inorganic, used by itself or as an ingredient in medicine".

It is clearly important to make a distinction between the discovery or synthesis of a new chemical compound and its introduction as a drug for therapeutic purposes. To take some outstanding examples. The foxglove was identified and named *Digitalis* by Fuchsius in 1542, but its powerful diuretic properties were not recognized until 1775 and, meanwhile, it was used for various other purposes. Sulphanilamide was first synthesized by a Viennese chemist named Gelmo in 1908 (at a time when Ehrlich's great chemotherapeutic researches were in progress), but its powerful antibacterial properties were not revealed until 1935 when some French investigators showed that the original sulphonamide drug, prontosil rubrum, owed its activity in the body to its conversion to sulphanilamide. Thus, from 1908 until 1935 sulphanilamide was just an organic chemical compound, but in 1935 it became a drug as well. Other examples are the well-known substance DDT, which was first synthesized in 1873 but not used as an insecticide until the Second World War, and penicillin which, though recognized as an antibacterial agent in 1928 by Fleming, was not made available for therapeutic use until the work of Florey, Chain and their colleagues some twelve years later.

Although there may be dramatic moments in the discovery of new drugs, it is impossible to know at once that an observation made in the laboratory, or even in the clinic, will be generally valid in all circumstances. Some apparently important discoveries have just petered out either from failure to confirm early findings or because the new drug has had unsuspected toxic actions. As a pharmacologist, I am sometimes asked what I think about some preliminary report, perhaps in a newspaper, of a new drug for which startling claims have been made. The correct reply is, what I believe that great clinical scientist, Sir Thomas Lewis, used to say when he came across some new observation in the literature, "interesting if true", but I have yet to find anyone who is satisfied with this answer. The establishment of the therapeutic value of a new drug is an empirical process which has to allow for initial enthusiasm, reactive pessimism and final balanced judgment. This all takes time, and until the drug has passed through all the stages of demonstration of pharmacological action, preliminary trial in man, controlled clinical trial and general usage in practice for months or years it is impossible to say precisely what has been discovered, since discovery means finding out the drawbacks as well as the virtues of a drug.

It is commonly thought that from prehistoric times people have everywhere sampled the plants, animals and minerals of their environment for their possible use as food, and that in this process they have stumbled, quite by chance, on pharmacological as well as nutritive actions, and that as a result folklore about the action of crude drugs has accumulated over the centuries. Chauncey Leake[1] has described such empirically obtained and empirically applied knowledge of drugs as 'protopharmacology', but before we smile indulgently at this name we should perhaps remember that the properties of opium, cinchona bark, ipecacuanha, santonin, squills, belladonna, curare, coca, ergot, ephedrine, vegetable purgatives and alcohol were all discovered by protopharmacologists.

However, it may be that some of these drugs were discovered in a different way, and the famous medical historian Henry Sigerist[2] has pointed out that treatment of disease by primitive peoples is a strange mixture of empirico-rational, magical and religious elements. If, for example, disease is attributed to the intrusion of foreign objects or demons into the body, treatment will be based on very different assumptions from those which underlie twentieth-century Western medicine, though starting from primitive premises therapeutic practice appears quite logical. Now the most potent method of driving out spirits was exorcism, the expelling of demons through the magic power of the word, and even other methods of treatment were usually accompanied by incantations. In ancient Egypt (and in medieval England) incantations represented a perfectly legitimate form of therapy not only for disease of magico-religious origin but also for the treatment of conditions such as poisoning by scorpion stings or snake bites, burns of the skin and hæmorrhoids But incantations were transitory affairs, the magician spoke the magic words, some rites were performed, and all was over

---

* Substance of a lecture delivered on June 6 at the University of Oxford in the series "Science and Economics in Chemical Technology".

In some cases such a brief ceremony resulted in a cure, but most patients were probably not suddenly improved and felt a strong desire to prolong the influence of the magic force This was done by charging an object with the magic force, making it thus an amulet or talisman Amulets might be simple objects such as a band of fine linen over which the words were spoken or on which they were written, or costly jewellery such as beads of gold, and rings of amethyst In Egypt, as in all ancient civilizations, minerals, metals, plants, every object animate and inanimate, possessed magic virtues Another amulet consisted of evil-smelling herbs, of garlic, and of honey which is sweet for men but horrible to ghosts This was to be applied externally to protect a child against demons, but in other cases herbs, garlic and honey over which a spell had been spoken were consumed by the patient A prescription of drugs thus charged became an internal amulet that exerted its power from inside the body, though it was not the drug in itself that was effective but the words spoken over it made it so The art of medicine consisting in selecting the right drugs, preparing them in the magically correct way and speaking the appropriate words over them One such incantation on drinking a remedy went as follows

"Come remedy ! Come thou who expellest evil things in my stomach and in these my limbs ! The spell is powerful over the remedy Repeat it backwards ! Dost thou remember that Horus and Seth have been conducted to the big palace at Heliopolis when there was negotiated of Seth's testicles with Horus, and he shall get well like one who is on earth "

Sigerist[2] suggests that the majority of Egyptian drugs became part of the materia medica for magic reasons, but that a sound empirical knowledge grew up as well The inherent magical virtue of a drug might coincide with its pharmacological effect The virtue of castor oil taken internally whether magical or empirical was always a cathartic one The day must have come when drugs were prepared and given without incantation This was the moment when magic and medicine separated

Now, although most of the drugs used by ancient and primitive peoples have no significant pharmacological actions in our sense, it is probably a mistake to assume that such remedies were not beneficial Indeed, in the light of recent evidence on the powerful effects of placebos and the considerable influence which an enthusiastic doctor can exert on the effects of drug treatment it seems to me very likely that these 'irrational', 'unscientific' remedies were very effective Primitive people are highly suggestible, and it is not difficult to imagine that an incantation would enormously enhance the virtues of the feeblest of drugs I am sure that some of our primitive ancestors would have made better use of tranquillizers and psychic energizers than does the modern physician participating with Olympian detachment in a controlled clinical trial I have heard rumour of a contemporary medicine man who finds chlorpromazine a tremendous boost to his magical powers This might be the best way of evaluating such drugs !

It is of interest to consider why so few new drugs were discovered from the time of ancient Egypt right up to the nineteenth century The reasons are not far to seek The sources of new drugs were confined to herbs, minerals and animal sources, there was no knowledge of how drugs worked, there was no chemistry to help isolate active principles let alone to synthesize new chemical compounds, there were no fruitful theories of disease, there were difficulties in diagnosis, differences of opinion were settled not by experiment but by argument influenced by an undue respect for authority, and superstition and quackery abounded There were doctrines, if not theories, of disease, and drugs were administered according to the doctrine most generally accepted at any given time The most persistent was the doctrine of the humours which guided therapy from the Hippocratic era until the early years of this century, and was responsible for much purging, vomiting, sweating, blistering and the letting of seas of blood The doctrine appears to have produced no discoveries of new drugs, and its only contribution to human happiness appears to have been its introduction of some delightfully descriptive words like sanguine, choleric, melancholic and phlegmatic into the language

Some people disliked theories about medicine and preferred to rely on experience alone, but Poynter and K D Keele[3] have emphasized that neither theorists nor empirics knew how to answer the question Does a drug work ? This was because they were all subject to the very persuasive logical error that if *B* follows *A* then *B* is caused by *A*—*Post hoc ergo propter hoc* They could not conceive the possibility that if a patient with, say, an acute fever was treated with a drug and recovered, that recovery might have occurred without the drug at all Thus, whatever drug was used was given the credit for the cure Further, they did not seem to be aware of the placebo effect though unconsciously they made full use of it In this climate it is no wonder that in diseases in which the placebo effect could not be exerted their remedies were of little value

After considering the numerous reasons for lack of progress in therapeutics through the centuries, it is most refreshing to turn to the constructive work of a man who in the eighteenth century used the empirical method to make an outstanding and well-documented therapeutic discovery which I shall discuss at some length, because it shows what opportunities had always been there for the taking and what can be done by practice founded on experiment and observation in the absence of general principles.

I refer to the discovery of the actions of digitalis or the foxglove by the famous Birmingham physician, William Withering, who introduced the drug as a treatment for dropsy in 1775 Before Withering's time, digitalis had been variously used as an emetic, a purgative, an expectorant, as a treatment for epilepsy and scrophula (tuberculous ulceration of the skin) and to promote the healing of wounds For one or more of these purposes it had been introduced into the *Pharmacopœia of London* in 1721 but was later omitted

In his book *An Account of the Foxglove*, published in 1785[4], Withering first discusses the ways in which the medicinal properties of animal and vegetables might be found out He realizes that "the more obvious and sensible properties of plants, such as colour, taste and smell, have but little connexion with the diseases they are adapted to cure, so their peculiar qualities have no certain dependence upon their external configuration" He then points out that "we have hitherto made only a very small progress in the chemistry of animal and vegetable substances" and that "Their virtues must therefore be learnt either from observing their effects upon insects and quadrupeds, from analogy, deduced from the already known powers of some of their congenera, or from the empirical usages and experience of the populace.

"The first method has not yet been much attended to, and the second can only be perfected in proportion as we approach towards the discovery of a truly natural system, but the last, as far as it extends, lies within the reach of everyone who is open to information, regardless of the source from whence it springs.

"It was a circumstance of this kind which first fixed my attention on the Foxglove. In the year 1775 my opinion was asked concerning a family receipt for the cure of the dropsy. I was told that it had long been kept a secret by an old woman in Shropshire, who had sometimes made cures after the more regular practitioners had failed. I was informed also that the effects produced were violent vomiting and purging, for the diuretic effects seem to have been overlooked. This medicine was composed of twenty or more different herbs, but it was not very difficult for one conversant in these subjects, to perceive, that the active herb could be no other than the Foxglove."

I have always been intrigued with the apparent ease with which Withering selected the foxglove as the active herb among a mixture of twenty. How did he do it? Was this hindsight when he wrote about it ten years later, or was it indeed a choice based on knowledge or experience of the actions of all the components of the mixture? I think that the latter is probably the case, because Withering was not only a very able physician but also a most distinguished botanist who at this very time was completing his book on *The Botanical Arrangement of All the Vegetables Naturally Growing in Great Britain*. The preface to this book, which was published in 1776, contains much useful information about plants used as foods, and those poisonous to cattle swine, dogs, birds and even insects. As a medical man, he must also have known about the actions and uses of plants in the treatment of disease, so that Withering was extremely well equipped to exploit the clue which chance presented to him. Moreover, he was a natural clinical scientist and pharmacologist, and it is most interesting to watch his reactions to situations comparable with those that arise to-day in the therapeutic evaluation of new drugs.

Withering then undertook a preliminary, or as we should say a pilot, clinical trial, a difficult and crucial stage in the introduction of any new drug, in which ethical problems arise in selecting and treating patients with a new unproved drug that may perhaps be harmful to the patient. Withering solved this problem very simply by making his preliminary observations on the sick poor of Birmingham, of whom he saw between two and three thousand a year free of charge. He gave digitalis to a variety of cases and found it to be a powerful diuretic, though at first he used too large doses, arguing by analogy with squills (long known as a diuretic) that it should act best on the kidney when it excites nausea. He admitted that he had little time to devote to these patients and that two or three of them only, in which the medicine succeeded, did he find mentioned among his papers. Nevertheless, in his book *The Botanical Arrangement* he ventured to assert that the *Digitalis purpurea* "is certainly a very active medicine and merits more attention than modern practice bestows upon it". By 1776, however, he had not yet introduced it "into the more regular mode of prescription", which I take to mean that he had not yet used it on his private patients, but "a circumstance happened which accelerated that event. My truly valuable and respectable friend, Dr. Ash, informed me that Dr. Cawley, then principal of Brazen Nose College, Oxford, had been cured of a Hydrops Pectoris, by an empirical exhibition of the root of the Foxglove, after some of the first physicians of the age had declared they could do no more for him. I was now determined to pursue my former ideas more vigorously than before. . . ."

Withering had first to decide which part of the foxglove plant would produce the most satisfactory and reliable effects. He soon came to the conclusion that the leaf was best, and in his book he gives details as to when the leaves should be gathered and how they should be dried to form a powder of constant activity. He clearly appreciated the need for standardization of digitalis and the fact that his recommended dose of the powdered leaf is still accepted to-day shows how successfully his empirical methods worked.

His *Account of the Foxglove* consists mainly of case reports, largely his own observations, but also communications from other doctors. Withering may not have been a statistician but he certainly knew how necessary it was to avoid a biased presentation of his results. "It would have been an easy task to have given select cases, whose successful treatment would have spoken strongly in favour of the medicine, and perhaps been flattering to my own reputation. But Truth and Science would condemn the procedure. I have therefore mentioned every case in which I have prescribed the Foxglove, proper or improper, successful or otherwise." He is not only honest but hesitant to generalize, perhaps influenced by his Edinburgh teacher of medicine, William Cullen, of whom Withering wrote: "His modesty is such that whatever he advances as new he cautions us thoroughly to examine, and only to embrace with 'a slow consenting academic doubt'." (Fulton[5].)

Now, in any therapeutic trial of a new drug everything possible must be done to minimize the risk to the patient. One way of dealing with this ethical problem is to give the drug only to patients who are desperately ill and most unlikely to recover with available methods of treatment. If a new drug works in such conditions it must be a very effective remedy indeed, and if it should fail or prove toxic, or even cause death, the course of events has merely been hastened, not altered. It was by force of circumstances, rather than choice, that Withering first gave digitalis to cases that "must be considered as the most hopeless and deplorable that exist". He goes on, "for some years I seldom prescribed it but when the failure of every other remedy compelled me to do it; so that upon the whole, the instances I am going to adduce, may truly be considered as cases lost to the common run of practice and only snatched from destruction by the efficacy of the Digitalis; and this in so remarkable a manner that if the properties of that plant had not been discovered, by far the greatest part of these patients must have died". It is against a similar, or even more hopeless, background that many new drugs have been, and are being, tested in patients with inoperable cancer, and so far, with one or two minor exceptions, without the happy issue that Withering frequently achieved with digitalis in the treatment of dropsy.

There is no justification for the introduction of a new drug into medical practice unless it is in some way better than existing drugs or other methods of treatment. A new analgesic should have advantages over morphine or aspirin, a new antibiotic should do something which existing ones do not, and new cortisone-like compounds should be more effective and less harmful than those now in use. Withering made this point clearly in relation to digitalis when he said: "I wish the reader to keep in view that it is not my intention merely to introduce a new diuretic to his acquaintance, but one which, though not infallible, I believe to be much more certain than any other in present use". In many of his case records of the successful use of digitalis he mentions the previous unsuccessful use of squills, until that time regarded as the most effective diuretic drug.

All drugs can produce harmful effects of some kind or other, certainly when an overdose is given and sometimes with doses in the therapeutic range. Withering recognized the effects of digitalis overdosage clearly enough—sickness, vomiting, purging, giddiness, confused vision, objects appearing green or yellow, slow pulse, even as slow as 35 in a minute, cold sweats, convulsions, syncope, death. Some of these effects had long been known, witness its therapeutic use as an emetic and purgative. Withering's contribution lay in his ascribing the beneficial effects of digitalis in dropsy to its diuretic action, and in showing that this action could in favourable cases be brought about by doses too small to produce sickness or any other affliction. Those dropsical patients who failed to show the diuretic response to digitalis were particularly liable to suffer toxic effects. To take account of both favourable and unfavourable cases, Withering recommended that digitalis powder be given in doses of 1–3 grains twice daily and "let it be continued, until it either acts on the kidneys, the stomach, the pulse, or the bowels; let it be stopped upon the first appearance of any one of these effects and I will maintain that the patient will not suffer from its exhibition, nor the practitioner be disappointed in any reasonable expectation".

Withering realized that digitalis was not effective in all cases of dropsy, but in spite of his cryptic comment "That it has a power over the motion of the heart, to a degree unobserved in any other medicine, and that this power may be converted to salutary ends" it was not possible for him to attain to the modern view that digitalis only works in those cases where œdema or dropsy is due to heart failure, that its primary effect is to improve the efficiency of the heart's action, increase the force of ventricular contraction, increase the amount of blood pumped out by the heart and thereby to improve the function of the kidney so that the œdema fluid is excreted as urine. If Withering had indeed expressed such a view it would have been pure speculation, for the very idea of heart failure as a cause of dropsy was not propounded until the early nineteenth century by Corvisart, Napoleon's physician.

I have referred to Withering at some length because I think his *Account of the Foxglove* is a wonderful demonstration of what can be achieved by empirical methods. But I think, too, that it was because there was no rational explanation as to how digitalis worked that the drug was used to such poor effect during the nineteenth century. Even when the association between heart failure and dropsy was appreciated, it was thought that digitalis acted primarily as a diuretic by an action on the kidneys and that the function of the heart improved as a consequence of the removal of the accumulated fluid from the body[6]. It was still used, too, for the treatment of consumption, and even Ferriar[7], who is often regarded as the first to appreciate that digitalis acted primarily on the heart when he said "the power of reducing the pulse is its true characteristic", and Kingslake[8], who claimed that it led to "augmented strength and slowness of pulsation, and also the transmission of a larger quantity of blood through the sanguiniferous system in a given time" were thinking in terms of its beneficial effects in pulmonary tuberculosis and not of its diuretic action in heart failure.

It was not until the early years of this century that Cushing, Mackenzie and Lewis put forward an acceptable rational explanation for the action of digitalis in heart failure. Mackenzie noted that digitalis was most effective in patients who had heart failure resulting from old-standing rheumatic affection of the heart with dilatation and an irregularity of the heart beat which he called "auricular paralysis" and now known as auricular or atrial fibrillation. In these cases it not only slows the rate of the heart "but the size of the heart diminishes, the urine increases and the dropsy disappears"[9]. Lewis[10] wrote that "the chief service of digitalis is to control ventricular rate in cases of this type. By slowing the ventricle it decreases the expenditure of energy". He described digitalis as a "cardiac hypnotic" which conserves the heart's energy and prolongs its rest.

Others, however, were impressed by observations that digitalis was sometimes very effective in heart failure with normal rhythm and in such cases relief can be obtained with very little slowing of the heart rate. Modern experimental work has shown that digitalis works by helping the failing heart muscle to make the most efficient use of the energy released by the chemical reactions within the muscle. In this way it can be of benefit in the treatment of heart failure whatever the rhythm.

Thus digitalis, an outstanding empirical discovery, has only attained its full therapeutic status since its mode of action was understood.

The rational discovery of new drugs was not feasible before the rise of pharmacology as a science during the nineteenth century; this in turn depended on the development of modern chemistry, with its ability to synthesize pure compounds and to extract active principles from natural sources, and also on the growth of physiology and bacteriology. During the nineteenth century the modes of action of the newly isolated alkaloids on the various systems of the body were studied by, among others, François Magendie (1783–1855) and his famous pupil, Claude Bernard (1813–78), who analysed the mechanism by which the arrow poison, curare, caused muscular paralysis. Pasteur's researches on the germ theory of disease paved the way for Lister's demonstration in 1867 of the antiseptic action of carbolic acid, which was the first hint of the possibility of chemotherapy in the modern sense. In the latter half of the nineteenth century the physiological role of the endocrine glands was steadily elucidated, initially by accurate clinical observation, and the way was thus prepared for the subsequent isolation and synthesis of hormones to be used in the treatment of endocrine deficiencies. However, in spite of the introduction of such drugs as nitrous oxide, ether and chloroform as general anæsthetics in the 1840's, of chloral hydrate as the first synthetic hypnotic drug in 1869, of cocaine as a local anæsthetic in 1884, and the synthesis of aspirin in 1899, the nineteenth century was a period rather of preparation than fulfilment. At the turn of the century, fever due to bacterial infections was treated in a semi-logical way by drugs of the aspirin type which merely lowered the temperature without affecting the bacteria; it took thirty-five years and more to find drugs which would lower body temperature by eradicating the infection.

'Chemotherapy' is the term introduced by Paul Ehrlich to describe the logical use of drugs to kill off parasites which cause disease.

Quinine, or rather cinchona bark, is really the origin of chemotherapy. Cinchona bark was discovered at some unknown time by empirical or other means as a remedy for the ague (or malaria) in South America; it was introduced into Europe during the seventeenth century, and in 1820 the active principle, an alkaloid named quinine, was isolated by two French chemists, Pelletier and Caventou. At this time the cause of malaria was not known, but quinine was of established empirical value, though, like digitalis in dropsy, it was not used to the best advantage. A crucial moment in the development of chemotherapy came in 1856 when William Henry Perkin, at the age of eighteen, attempted to synthesize quinine from a chemical compound called toluidine. He failed, but this experiment led directly to another in which he made the first artificial dye, aniline purple or mauve. He thus initiated the synthetic dyestuffs industry, but the full exploitation of this field was taken over by the Germans during the last quarter of the nineteenth century. It was in this environment that Ehrlich grew up and dyes seemed to fascinate him all his life[11]. His M.D. thesis, written in 1876, when he was twenty-four, dealt with the theory and practice of histological staining with particular reference to aniline dyes; he studied the distribution of dyestuffs first in blood and then in living animals and showed that certain dyes stained specifically certain organs or types of cells[12]. With the rapid contemporary developments in bacteriology it was natural that Ehrlich should turn his attention to the staining of bacteria, and after others had shown that some dyes could kill bacteria, he made his first experiment in chemotherapy in 1891. He observed that methylene blue stained malarial parasites very effectively, and Ehrlich and Guttman then successfully used this dye in the treatment of some patients with tertian malaria, though the results were not good enough to warrant the substitution of methylene blue for quinine. It is interesting to consider why this promising development went no further at that time. The reason was that although the malarial parasite had been discovered in the red blood cells of malarial patients by Laveran in 1880, it was not until 1897 that Sir Ronald Ross demonstrated transmission of the parasite by mosquitoes. Thus, in 1891, Ehrlich had no rational method for testing antimalarial substances in animals, and it would have been quite unjustified to subject patients to tests with new and untried drugs. Indeed, it was not until 1924, nine years after Ehrlich's death, that experimental malarial infection of small birds (canaries) was used in Germany for the testing of new antimalarial drugs. This helped in the discovery first of plasmochin and then, in 1933, of atebrin, which under the name 'mepacrine' was of decisive value to the allied armies in the Second World War after the Japanese had overrun Java, the main source of the world's supply of quinine.

As Sir Henry Dale[13] has said, the real opening of Ehrlich's campaign for the synthesis of artificial chemotherapeutic remedies began with the discovery by Laveran and Mesnil in 1902 that mice and rats could be experimentally infected with trypanosomes, the organisms responsible for sleeping sickness. In the following year Ehrlich discovered a benzidine dye that could cure such laboratory infections, and he aptly named it trypan red. Although this dye proved to be unsuitable for the treatment of human trypanosomal infections, it provided "the real point of departure for the new scientific adventure of chemotherapy"[13]. Ehrlich's work was guided by theoretical principles concerning the interaction between drug and parasite. His first principle was "*Corpora non agunt nisi fixata*", meaning that parasites were only attacked by drugs which became fixed to their so-called chemoreceptors. His aim was to find drugs which had a stronger specific affinity for infecting parasites than for the organs of the infected host, or in Ehrlich's terms, a stronger "parasitotropic" than "organotropic" activity. In ordinary language, the drug must kill the infecting parasite without harming the patient. Ehrlich's enthusiasm and hopes for chemotherapy were unbounded and are well summed up in his objective "*Therapia magna sterilans*" or complete recovery with one massive dose of drug.

Ehrlich's outstanding contribution to chemotherapy was the introduction of the organic arsenical drug salvarsan for the treatment of syphilis in 1910. In 1905, the micro-organism responsible for syphilis was identified as a spirochæte and, in 1906, the Wassermann blood serum test for the diagnosis of syphilis was discovered. Actually, salvarsan or '606' (606th compound of the series) was made in 1907, but its importance was at first overlooked by an incompetent assistant, and it was not until a Japanese named Hata joined Ehrlich in 1909 that its remarkable activity in curing experimental syphilis in rabbits was revealed, and in 1910 its successful use in the treatment of human syphilis was announced. One is lost in admiration at the speed with which Ehrlich exploited the opportunities which came his way. His achievements are a wonderful illustration of the blended application of logic, empiricism and opportunism to a problem of practical importance. Sir Henry Dale has written about this discovery: "It would be difficult to exaggerate the effect on medical opinion throughout the world of this first success in producing by an experimental research organized to that end, a specific remedy, acting directly on a disease of such importance as syphilis".

The discovery of drugs for the treatment of bacterial infections—bacterial chemotherapy—which seemed a logical enough development, proved a much harder nut to crack, and it was not until 1932 that the first effective antibacterial sulphonamide—appropriately a dye called prontosil rubrum—was synthesized in Germany by Mietsch and Klarer, and shown to be effective in experimental streptococcal infections in animals by Domagk, the first clinical reports of its successful use appearing in 1935. Why was there such a delay between the discovery of salvarsan for syphilis and prontosil for bacterial infections? One reason seems to be that in testing new compounds, far too much reliance had been placed on their ability to kill bacteria growing in cultures outside the body. Only if a compound could kill bacteria under such conditions in ½ hr was it tested further for its capacity to kill bacteria in an experimentally infected animal. Now, prontosil rubrum had no effect on bacterial cultures growing *in vitro* but was highly active against infections *in vivo*, owing as we have seen to its conversion to sulphanilamide in the body, but even sulphanilamide would not have shown up in a brief *in vitro* test with the culture media then in common use. The famous physiologist, Karl Ludwig, once said, "Die Methode ist alles". Here is a case in point.

But since the sulphonamides were not discovered until the mid-1930's one may well wonder what was happening to penicillin, the activity of which against certain bacteria growing on a culture plate Fleming had first revealed by a brilliant piece of opportunism in 1928. Here is a different story, the difficulties being two-fold. First, when chemists tried to isolate penicillin from the medium on which the mould *Penicillium notatum* had been grown they found that the usual methods of extraction caused it to disappear like a will-o'-the-wisp, and by 1932 they had given up in despair. Fleming's original solutions of penicillin were actually tested on infected human wounds but were not strong enough to have much effect and were far too weak to act on generalized infections. One can only speculate on what would have happened had Fleming tested his solutions on experimental infections in animals, which, following Ehrlich, he should have done. However, the second and equally important reason for the failure to develop penicillin at that time was the prevailing sceptical climate of opinion which regarded bacterial chemotherapy as a pipe-dream. I remember this period very well, as in the early 1930's I was a medical registrar at the Middlesex Hospital, and my duties included the treatment of patients with syphilis. Here, with our neosalvarsan and bismuth, we said, was chemotherapy, but for our patients with pneumonia, septicæmia and infections of the kidney there were no specific drugs at all, and we all felt that bacterial chemotherapy was a hopeless quest. It is true that occasionally we gave injections of drugs such as mercurochrome and gentian violet to patients with septicæmia, who, like Withering's patients, had to be "considered as the most hopeless and deplorable that exist", but with the unhappy difference that the greater part of our patients died. But what did Fleming think about all this a little more than two years after his discovery of penicillin? Early in 1931 he was the main speaker at a discussion at the Royal Society of Medicine on the intravenous use of germicides, and he produced evidence that all the antiseptics which had hitherto been tried in this way were more lethal to the white cells of the blood than to the bacteria they were designed to kill[14]. However, he did find grounds for the faint hope that "some mercury compounds will be elaborated which will be more potent than those cited, and it is possible that by the application of this principle—the use of a chemical not to kill bacteria but to act as an adjuvant to the natural defences—the most beneficial results will be obtained in that dreaded condition, a generalized *Streptococcus pyogenes* infection". Penicillin was not mentioned during the whole meeting.

Such was the atmosphere at that time and I have always felt that the discovery of the sulphonamides, though by itself a great therapeutic advance, achieved even more by fanning a favourable wind of change which, reaching Oxford in 1939, inspired Florey, Chain and their colleagues to produce penicillin as the outstanding antibacterial agent of all time.

I am not going to discuss the numerous further advances in bacterial chemotherapy, but I would like to comment on the reason for the relative failure of what has been called, over-ambitiously, the chemotherapy of cancer. It is both logical and empirically beneficial to use drugs to kill bacteria and other parasites which cause disease. This has been possible because these micro-organisms differ sufficiently from the cells of the body to be susceptible to drugs which do not harm the patient. But the cells of a cancerous growth much more closely resemble the normal cells of the body and drugs which kill off these malignant cells inevitably damage some normal cells as well. A new approach may well be needed here.

In quite other fields an understanding of causal factors in disease has also led to the more rational use of drugs. The antihistamines could only have been developed after it had been established that histamine was a constituent of many tissues and that its liberation in an active form was responsible for allergic reactions such as urticaria and hay fever. The therapeutic administration of hormones in diseases due to reduced secretion from endocrine glands, for example, insulin in diabetes mellitus and thyroid hormones in myxœdema, is entirely rational and empirically effective. The giving of vitamin D for rickets, or vitamin C for scurvy is also rational therapy, but the use of vitamins as 'tonics' is not.

Sometimes a successful therapeutic agent may throw light on the nature of a disease, as happened when Minot and Murphy in 1926 showed, on an erroneous hypothesis, that liver treatment was a pernicious anæmia. In other cases a drug introduced for one purpose may turn out to have a therapeutic effect of quite a different kind. In 1920, Saxl and Heilig were testing an organic mercurial drug for the treatment of syphilis in a patient with heart failure, and the unexpected profound diuresis which followed led to the introduction of the valuable mercurial diuretics. These and other happy accidents recall Francis Bacon's comment "That medicines and cures were first found out, and then after the reasons and causes were discoursed, and not the causes first found out, and by light from them the medicines and cures discovered" (*Celsus—De Medicina—*1*st Cent. A.D.*).

In some diseases we are still too ignorant of causes to know how best to look for therapeutic remedies. For example, the nature of the changes in the brain which provoke disorders of the mind are far too little understood to provide a logical foundation for the use of the many drugs introduced for treatment, and in this case even their empirical value is in doubt.

Over the centuries new drugs have been discovered by lay people, practising doctors, and research workers in university departments or medical research organizations, but latterly the discovery of new drugs has become almost exclusively a business matter. It is therefore interesting to consider how the pharmaceutical industry organizes its search for El Dorado. It realizes that new drugs cannot be designed by logical deductions from valid general principles, that chemical theory alone is not enough. The relation between chemical structure of a compound and its biological activity is the fundamental problem of pharmacology, and most research is conducted on the hypothesis that drugs act by combining with specialized parts of cells called receptors, and that such combination in some way alters cellular activity. However, while a great deal is known about the chemical properties of drugs, very little is known about the nature of receptors, so it is not surprising that interactions between the two should sometimes have unexpected consequences. We have not yet reached the stage optimistically forecast by Thomas Huxley[15] when he addressed the famous International Medical Congress of 1881 and said "sooner or later the pharmacologist will supply the physician with the means of affecting, in any desired sense, the functions of any physiological element of the body". Perhaps 'later' is the operative word. To deal with this situation the research department of a pharmaceutical firm organizes its activities on the basis of provisional hypotheses and empirical tests. Logic provides a direction to research and experience decides whether this is the right direction or no, and in providing information may, by a sort of feedback mechanism, initiate new hypotheses and so lead to fresh experiments.

Pharmacology is the most eclectic of all the medical sciences. Apart from its own theory and practice it seeks inspiration and guidance from chemistry, biochemistry, biophysics, physiology, bacteriology, pathology, immunology and, of course, from medicine itself. The practical application of all this is seen in any industrial research institute where departments, or at least individuals, dealing with these various activities are to be found and where the emphasis is on team work. It is in the nature of things that the chemists who make the potential new drugs should initiate most of the research, but it is the pharmacologist who is the arbiter, usually a very destructive one, since only one compound in several hundred is likely to find any therapeutic application. It might therefore be said that the chemist proposes and the pharmacologist disposes, but the function of the latter is much more constructive than this suggests since the success of the whole project depends on the use of appropriate experimental pharmacological tests, and that it is he who is most likely to make 'lucky strikes'.

Any type of research has to be planned, which means that work must start from some hypothesis, which in our case will take account both of the nature of the disease against which the drug is to be effective and also the chemical constitution and pharmacological actions of drugs previously used for treatment. If the disease is a bacterial infection, experiments will be done to test the new drug's efficacy in killing these particular bacteria when grown *in vitro* and also to find out whether it can protect infected animals. If the aim is to produce a new drug for the treatment of, say, high blood pressure, the problem is more difficult, since the disease cannot be satisfactorily mimicked in experimental animals. In such a case the new drug would be studied for its ability to lower the blood pressure in normal animals and in animals in which the pressure has been experimentally raised, but these are not always reliable criteria. If a drug is to compete with morphine as an analgesic it must be capable of suppressing responses to noxious stimuli—but these examples are enough.

The other side of the picture is the chemical constitution of existing drugs of the different pharmacological or therapeutic groups. Much research is devoted to the making of chemical modifications of existing drugs to try to increase their effectiveness and reduce their toxicity. Thus, we have spates of antihistamines, cough suppressants and tranquillizers. This type of research is profitable to the industry, but excessive multiplication of drugs with similar actions can be most confusing to the doctor.

It is very difficult to plan a major advance in drug therapy, but what a research institute can aim at is 'organized opportunism', the ability to spot and exploit a happy accidental discovery, which may arise from work directed to quite a different end. To avoid missing opportunities, all new chemical compounds are submitted to numerous pharmacological tests of many different kinds—a process called 'screening' a drug. By thus spreading the net it is hoped to pick up the very occasional very big fish, but nothing illustrates better the role of empiricism in modern pharmaceutical research.

Although the discovery of new drugs is a form of applied research, I do want to emphasize very strongly that such research can only flourish if it receives constant nourishment from so-called pure research, conducted in an academic atmosphere where problems are studied for their own sake. This is to my mind the only way in which the process of discovering new drugs can become more rational, so it is very important that fundamental research on the intimate mechanism of drug action, by chemists, pharmacologists, biochemists, microbiologists and others, should be given more support than it now enjoys. I should also like to see freer communication between workers in academic and applied forms of research so that each can better appreciate the other's point of view, and I would recommend that all who work in the microcosmic atmosphere of the laboratory should now and again sniff the macrocosmic air in which patients actually live.

And now for the rest of Huxley's prophecy, made several years before Ehrlich talked of magic bullets: "It will, in short, become possible to introduce into the economy a molecular mechanism which, like a very cunningly contrived torpedo, shall find its way to some particular group of living elements, and cause an explosion among them, leaving the rest untouched." One might perhaps hope that with the incorporation of modern homing devices, and maybe also biological nuclear explosives, Huxley's torpedoes could be given instructions for the logical treatment of all ills; but I for one would welcome an assurance that accidental explosions will never be empirically recorded.

I thank Dr. F. N. L. Poynter, chief librarian of the Wellcome Historical Medical Library, for his help with historical aspects of this article.

LONGEVITY OF MICRO-ORGANISMS

By Dr P H. A. SNEATH
National Institute for Medical Research, London, N W7

THE maximum time that micro-organisms can survive in a dormant state is of interest from several points of view as a guide to the preservation of cultures, to throw light on the mechanism of dormancy and in relation to the transmission of life through space Lately, the advent of space technology has raised the question of interplanetary contamination by micro-organisms carried by space rockets, and the dangers of this have been discussed elsewhere[1-3] The difficulties in disinfecting space-vehicles[4,5] make it desirable to know how long micro-organisms may survive in them if protected from solar radiation, since these vehicles may remain in orbit for centuries and, should they later fall on a planet, they may be unsuspected sources of microbial contamination if they had not been sterilized before launching

Keilin[6] has summarized the data on longevity of organisms in a dormant state, which he calls 'anabiosis' The most remarkable record is the survival of seeds of the lotus *Nelumbo nucifera* in a peat bog for more than a thousand years Many other plant seeds are known to survive for a hundred years or more Some higher organisms can resist extremes of heat, cold and desiccation, for example, larvæ of the chironomid fly, *Polypedilum vanderplanki*[7] Micro-organisms have long been known to resist even greater extremes of heat, cold, desiccation and chemical disinfection, but much less is known about the length of time they can survive under favourable conditions Most of the information on this is summarized in Engley's extensive review[8] Claims that bacteria have survived in coal since it was deposited are not generally accepted[6] Bacteria have been reported from a mammoth frozen in Siberia[9], but the possibility of later contamination seems considerable, there is uncertainty on how long bacteria survive in permanently frozen soil[10,11] There is information on the survival of many pathogenic bacteria, and those which survive longest are bacterial spores, although some Gram-positive cocci live almost as long It is commonly considered that spores of *Bacillus anthracis* and *Clostridium tetani* are among the most resistant, and there are records of survival of these for thirty or forty years[12,13] One virus survived for 38 years in blood[14] The longest survivals that I have been able to trace are those reported by Wilson and Shipp[15] and by Jacotot and Virat[16] The former authors found viable spores of a thermophilic bacillus in a tin of meat which had been canned 118 years previously The latter authors reported that anthrax spores prepared by Pasteur in 1888 were alive 68 years later

Suitable material for such investigations is not easy to find Most of it is liable to recent contamination, since very little material has been sealed in a container impervious to penetration by micro-organisms The significance of the results therefore depends on showing that the count of viable micro-organisms is higher than can be readily accounted for by recent contamination One promising material for investigation is soil dried on the roots of plants in botanical collections Some of these plants were gathered more than three hundred years ago, and have since then been kept constantly dry The relative humidity in herbaria is generally rather low, and must in any event be low enough to prevent growth of moulds on the specimens There is therefore little likelihood that bacteria found in the soil on these plants can have multiplied since they were collected In a few instances this can be asserted with some confidence since the roots have been painted with strong solutions of mercuric chloride which would exclude any multiplication after the date it was applied. Although powerfully bacteriostatic at extreme dilutions, mercuric chloride is well known to possess very little bactericidal action, and recovery of most of the organisms occurs on culture in media containing an adequate source of sulphydryl groups[17,18] Nevertheless, in material not treated with mercury salts there is a possibility that multiplication of some micro-organisms may slowly occur even under the dry conditions in herbaria, for there are some data on desert soils and on soils studied at low humidities which suggest that this can occur[19] For various reasons mentioned here, this does not seem to be a likely explanation of the findings reported here.

Soil samples Through the kindness of the Keeper of the Herbarium, Royal Botanical Gardens, Kew, Surrey, and the Keeper of the Herbarium, British Museum (Natural History), I was able to obtain samples of soil from the roots of a number of plants, mostly grasses, which had been gathered and dried between 1640 and the present day Granules of soil were detached from the roots with sterile forceps and placed in small sterile tubes Small fragments of mounting paper and of florets and leaves served as control specimens The soil was crushed to a fine powder with a sterile glass rod, and by using a small platinum scoop which held a known weight of soil and which could be sterilized by flaming, known amounts of soil were transferred to the culture media described here Where necessary, dilutions were made in the culture media or in sterile distilled water Replicate viable counts gave reasonably consistent results

The following media were used for viable counts

Nutrient agar (for 'total' counts) Meat extract agar[20] to which had been added 0 1 per cent (w/v) of Difco yeast extract and 0 1 per cent of thioglycollic acid (to neutralize mercury ions) was used as a pour plate medium The soil inoculum was added to 20 ml of the melted medium (cooled to 56°), and this was poured on to a solid basal layer of 20 ml of the same medium in a Petri dish After solidification, a top layer of 5 ml of uninoculated medium was poured. The plates were incubated aerobically at 25° for five days, and the colonies counted

'Thermoacidurans' agar (selective medium for *Bacillus coagulans*) Difco 'Thermoacidurans' agar was used, composed as follows Bacto yeast extract, 5 gm , 'Proteose' peptone, 5 gm . glucose, 5 gm ; dipotassium hydrogen phosphate, 4 gm , agar, 20 gm , distilled water, 1 litre The medium was

autoclaved and cooled to 56° and than adjusted to *p*H 5 0 The agar, in 20-ml amounts, was inoculated with soil and pour plates were made A top layer of 5 ml was added The plates were incubated aerobically at 50° for two days

'*Oxoid' reinforced clostridial medium* (Oxo, Ltd, Queen Street Place, London, E C 4) This was used for pour plates and incubated anaerobically at 30° for five days Some strains of *Clostridium* were isolated, but with the oldest samples the colonies proved to be strains of *Bacillus*

'*Oxoid' Littman ox gall agar* (for fungi) was used with the addition of 30 µgm /ml of streptomycin Plates of this medium were inoculated with soil suspensions, spread with a sterile glass spreader, and incubated aerobically at 25° for five days

'*Oxoid' wort agar* (for fungi) was used with the addition of 'Novobiocin', 100 µgm /ml This antibiotic was recommended as selective for fungi by Butler and Hine[21] Surface inocula were made as above, and the plates were incubated for five days at 25°

Benedict agar plus 50 *µgm /ml 'Pimaricin'* (for streptomycetes) This medium is recommended for the isolation of streptomycetes[22] Surface inocula were made as above, and the plates were incubated at 25° for twelve days Some bacteria and some fungi grew in addition to the streptomycetes, and the colonies of the latter were therefore confirmed by examination with the low power of a microscope

Identification of bacteria Almost all the bacteria grown from the older soil samples were species of *Bacillus*, and they were identified by the usual tests[23-25]

The results of the examination of these soils are shown in Figs 1 and 2 It can be seen from them that fungi and streptomycetes do not survive for many years in dry soil samples This is in keeping with what little is known about their survival in soils, though some fungi may survive longer[26] The only viable organisms which are found in the older samples are sporing bacilli, almost all being aerobes of the genus *Bacillus* In Table 1 is shown the identity of these It is seen that the majority of those from the older soils are strains of the *Bacillus subtilis–pumilus–licheniformis* group Most of them were typical The longevity parallels the heat resistance of the spores[27]

Table 1 SPECIES OF *Bacillus* ISOLATED FROM SOIL SAMPLES OF DIFFERENT AGES

Species	No of isolates from soils of ages (yr) 0–50	50–100	100–200	200–320
B subtilis	29	12	9	4
B licheniformis	5	2	2	1
B pumilus	1	0	1	0
B coagulans	6	4	0	0
B firmus	1	0	0	0
B megaterium	3	0	0	0
B cereus	3	0	0	0
B circulans	4	4	0	0
B polymyxa	1	0	0	0

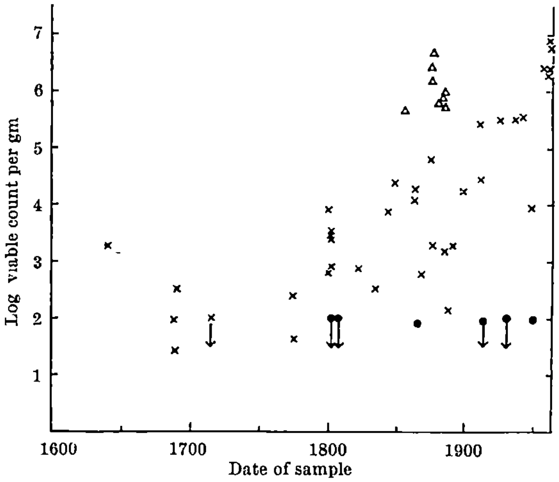

Fig 1 Viable counts of soils on aerobic nutrient agar The triangles indicate counts on sealed samples The circles indicate counts on materials used as controls, for example, leaves, florets, paper The arrows indicate that the counts were less than the value shown (no growth from 10 mgm of material)

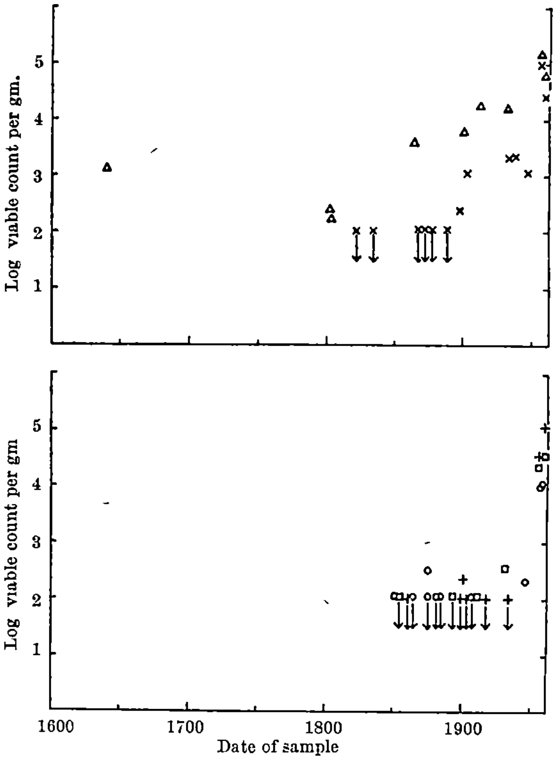

Fig 2 Viable counts of soils on selective media Upper part bacteria lower part fungi and streptomycetes × 'Thermoacidurans' agar, △, reinforced clostridial medium (anaerobic), □ Littman ox gall streptomycin medium, +, Wort agar with 'Novobiocin', ○, Benedict medium with 'Pimaricin'

For the meaning of the arrows, see legend to Fig 1

Fig 1 shows that the death-rate of bacteria in soil follows a line which may be somewhat curved There is a rapid fall in total viable count in the first few years owing to the death of many non-sporing bacteria Thereafter, there is a slower rate of death of more resistant forms such as fungal and bacterial spores After about 50 years the survivors are almost all spores of species of *Bacillus*, and the death-rate of these is slow There is a suggestion of a still slower component, representing the spores of the *Bacillus subtilis* group, which are viable in the oldest samples One would expect such an appearance on drying soil containing a very mixed population of microorganisms, and the overall curve is not unlike the decay curve of a mixture of radioisotopes of different half-lives

It is not easy to fit a curve to the very scattered points in Fig 1 We may, however, estimate that for soils more than 50 years old the slope is such that nine-tenths of the survivors die every 50 years, possibly with a more long-lived component (nine-tenths dying approximately every 100 years) If the last figure is correct, one can estimate that a ton of dry soil would still contain a few viable spores even after 1,000 years It will be seen from the figures that material such as the mounting paper, small fragments of leaves and florets, etc , had very low viable counts, which gives some confidence that the counts on the soil are not due to contamination since the date of collection The narrow spectrum of surviving forms in old soils (contrasting with the wide range of bacteria and moulds which can be isolated from freshly dried soil or from dust) also supports this There was no great difference between the viable counts from soils which had been treated with mercuric chloride and those which had not

A few samples of soil from Rothamsted Experimental Station were made available through the kindness of the director, Mr F C Bawden These had been collected from agricultural land in the latter half of the nineteenth century, and had been dried, powdered and stored in sealed jars These samples gave heavy counts of aerobic sporing bacilli, ranging from 3×10^{5} to 5×10^{6} per gm , most being of the *Bacillus cereus* and *Bacillus subtilis* groups Though they antedate the discovery of penicillin, many of these strains produced large amounts of penicillinase The high counts, as high as those in many recently collected samples, may have been due to better survival in sealed containers, or possibly to multiplication to very high levels during the early treatment of the soils (of which details are now not available) These results have not been included in estimating the death-rates, but are shown in Fig 1 as the triangular symbols These samples had very few moulds or streptomycetes, but some *Clostridium* colonies were found in anaerobic plates

A number of other materials have been briefly examined by the techniques given above Through kind permission of Dr P S Nutman, eighty soil cultures, mostly of soil bacteria, which had been set up in 1925 by Sir Gerard Thornton at Rothamsted, were examined These had been set up by adding to dry, sterile soil in plugged vials enough of a culture of the organism in liquid medium to moisten it thoroughly, the cultures were allowed to dry out and were preserved at room temperature and humidity in the dark In 1939 Sir Gerard Thornton had found 55 of the cultures still viable on culturing about 100 mgm of the soil In 1960 twenty of these were still viable As expected, most of the sporing bacilli were still alive, and most of the non-sporing bacteria were dead These results are similar to those of Jensen[28], though he obtained growth of *Rhizobium* after 45 years Viable counts on the known spore-forming organisms are of interest as indicators of the likely death-rate of different species in natural soil It was found that the viable counts per gram of three strains of *Bacillus cereus* var *mycoides* were approximately 5×10^{7}, 2×10^{8} and 9×10^{7}, for one strain of *Bacillus megaterium* it was approximately 4×10^{8}, and for seven strains of the *Bacillus subtilis* group the counts were approximately $1\ 5 \times 10^{7}$, 1×10^{8}, 4×10^{5}, 4×10^{6}, 4×10^{9}, 3×10^{9} and 6×10^{8} Very probably the original spore counts were about 5×10^{9} per gm when the soil tubes were first inoculated These figures do not suggest that *Bacillus subtilis* spores have a much slower death-rate than spores of the other species the data are, however, by no means conclusive

Through the kindness of Dr E O Callan, of Macdonald College, Quebec, some coprolites from Mexico were examined These were human fæces from the Meso de Guaje culture, and date from about 1500 B C They have been preserved in caves by very dry conditions The outer surface was thoroughly flamed and the coprolites broken open with aseptic precautions, and the fibrous material of the interior was cut out and cultured This material was sterile when about 100 mgm quantities were cultured in nutrient broth or in pour plates of nutrient agar aerobically and anaerobically No bacteriophages active on *Escherichia coli K*-12 were isolated In such fæcal material one would expect there to have been coliform bacilli, fæcal streptococci, spores of *Clostridium welchii*, and possibly spores of other *Clostridium* species and of *Bacillus* species The fæcal material was excellently preserved, and microscopically the structure of the plant residues was easily seen, and a few objects morphologically resembling bacteria were seen among the plant residues This material was examined by Miss Joan Webb of this Institute by gas phase chromatography, and was found to have the characteristic fatty acid pattern of fæcal lipids[29]

Dr Karl Schlabow, of the Schleswig-Holstein Museum, kindly sent some intestine from a peat burial of about A D 1000 (ref 30) The bowel was opened aseptically and found to contain white, waxy material, apparently fat derived from fæces, and it also showed the fatty acid pattern of fæcal lipids This was also sterile when about 50 mgm was cultured in pour plates as above However, the material had a low *p*H (about 5 4), as would be expected of material embedded in peat, and this would have caused accelerated death of the bacterial flora There was probably considerable multiplication of anaerobic bacteria after death and before the preservation of tissue by the penetration of acid materials from the peat so one would expect that *Clostridium welchii* spores and probably spores of *Cl sporogenes* and other putrefactive clostridia had been present originally Microscopically no objects resembling bacteria or their spores were seen

The results reported here seem unlikely to be accounted for by recent contamination of soil samples by dust or handling If they are accepted as substantially accurate, it is clear that viable micro-organisms can survive for centuries in soil under conditions of normal temperature and humidity. We cannot, therefore, expect contaminated space-vehicles to become sterile even after several centuries, and this implies that they may remain contaminated for periods longer than accurate records of their orbits and other particulars are likely to be preserved. It is therefore doubly important to avoid the launching of unsterilized space-vehicles, they may initially strike a planet and contaminate it, or they may become forgotten but still contaminated solar satellites It is also clear that even intense radioactive contamination of our planet is unlikely to lead to the extinction of all forms of life, since in protected places in glaciers or caves micro-organisms would survive until the radioactivity had largely decayed However, whether this is a cause for rejoicing is another matter The few data on the oldest material are not of much significance, they have been exposed to conditions which were not ideal for survival Under other conditions, for example the extreme cold of the antarctic ice-cap survival may be better Prof R H McBee (personal communication) has found more than 10^{3} viable coliform bacilli per gm in pony fæces from Scott's Antarctic Expedition of 1911, which had been continuously frozen for nearly fifty years

How long could life survive under the best conditions ? By this is meant conditions such that labile but essential metabolites are preserved, or provided in the environment at recovery, so that the organism has no difficulty in re-establishing its metabolism (probably a main cause of death in anabiosis) When we consider the survival of organisms over very long periods, we have to take into account the spontaneous chemical breakdown in those organic molecules which form the essential organizational structure of the cell, in particular, proteins and nucleic acids It seems likely that proteins break down more rapidly than nucleic acids Different amino-acids have different degrees of stability, alanine, for example, being very stable and tryptophan very unstable, and this is borne out by the results of examination of fossilized protein materials of various ages[31] These considerations are not entirely academic, since, as Lederberg points out[2], we should not discard out of hand all possibility of Avogadro's panspermia hypothesis that life has spread through the universe, and the Moon may have collected biological material in the past[1,32]

Becquerel[33] calculated that, at temperatures around absolute zero, micro organisms would survive for millions or billions of years This is obtained by extrapolation of survival curves obtained at much higher temperatures, but there seems to be no reason to doubt the general conclusion At such low temperatures not only would essential and labile metabolites be preserved, but the structural breakdown of proteins and nucleic acids would also be exceedingly slow The effect of the very high vacuum in space on micro-organisms is still uncertain, though recent work[34] suggests that it may not have a seriously lethal effect, and it would not apply to protected material

One of the uncertain factors in estimating the possible survival of life over very long periods of time is the influence of accumulated ionizing radiation While the chemical breakdown discussed here would not be important at temperatures near absolute zero, it is likely that ionizing radiations would produce damage to cells, either directly or through the production of ions and free radicals which, though they might be unreactive at these low temperatures, would presumably remain in the cell and become reactive when the cell reached an environment permitting recovery This would then, in theory, set a limit to the survival time even at absolute zero

We still know little about the effect of irradiation at low temperatures or *in vacuo*, but we may for present purposes assume a logarithmic death-rate such that 90 per cent of bacterial spores (which are among the more resistant of organisms) will be killed by an accumulated radiation dose of about 10^5 roentgens[35] If this dose is increased twenty-fold, we expect the survival to become effectively zero since, assuming the usual logarithmic relation between dose and survival, the survivors would be 1 in 10^{20} We may consider spores which are protected by a few centimetres of material from direct cosmic rays, electrons, ultra-violet radiation, etc In deep interplanetary space the radiation will probably be about 10 roentgens per year, most of it due to secondary X-rays formed by bombardment of the surface material In interstellar space the radiation may be much less, so that the radioactivity of the protective material itself becomes the main factor If the material is similar to granite, the dose will be about 0 1 roentgen a year, and in iron meteorites it is likely to be still smaller, perhaps 0 001 roentgen a year To achieve 10^5 roentgens will require in these cases respectively 10^4, 10^6 and 10^8 years In potassium-containing rocks, however, spores would receive radiation from the radioactive isotope of potassium (potassium-40) all around them, and this may be quite appreciable The range of the β-particles will be about 2 mm , and in orthoclase (potassium feldspar, $K_2O\ Al_2O_3\ 6\ SiO_2$) the dose-rate will be about 0 5 roentgen a year, due to the potassium-40

There remains one further limiting factor, and that is the irradiation produced by the decay of the potassium-40, which no organism can escape since potassium is universally distributed in living creatures A bacterial spore weighing 10^{-12} gm contains about 1,250 atoms of potassium-40, of which about 500 decay in 10^9 years, and in this period would yield a dose within the spore of about 750 roentgens This dose would kill very few of the spores, but little is known of the damage in cells due to the recoil energy of decay of potassium-40 If this behaves like decay of phosphorus-32 (ref 36), then a high proportion of spores might be killed over a period of 10^9 years For shorter periods this would not apply, and we may conclude that life could probably be preserved for periods of more than a million years, if suitably protected and maintained at temperatures close to absolute zero This may be relevant to the present-day interest in the possibility of life-forms in meteorites[37]

CLOUD PHYSICS

PROF B J MASON delivered his inaugural lecture on "The Physics of Clouds, Rain and Lightning" at the Imperial College of Science and Technology, London, on November 14 The lecture marked the occasion of Prof Mason's appointment to the first chair of cloud physics in the College*

Of the many problems which confront the cloud physicist some which have attracted particular attention are, first, the detailed processes which bring about the condensation of cloud droplets from water vapour, secondly, the mechanism which causes the tiny water droplets to freeze, and thirdly, the manner in which the small water droplets or ice crystals grow to a size sufficient to permit them to fall out of the cloud and reach the ground as precipitation

Broadly speaking, clouds form when air containing water vapour rises to levels at which the pressure is lower The resultant quasi-adiabatic expansion is accompanied by cooling until the temperature falls below that at which the air becomes saturated with water vapour The excess vapour then condenses, but it can only do so on small particles which act as nuclei for the small droplets The atmosphere contains many such particles One c c of London air may contain 10^5 particles the radii of which range from 5×10^{-7} cm to more than 10μ Sea-salt particles make good condensation nuclei They are formed over the oceans in the foam of breaking waves when air bubbles burst to produce small droplets of sea-water The latter evaporate, leaving behind the salt nuclei 0 1μ–10μ in diameter, or 10^{-15} gm –10^{-9} gm in mass The way in which these small salt particles form has been studied by high-speed photography of the bursting air bubbles

The formation of a cloud involves the growth of a population of droplets on condensation nuclei of various sizes Condensation occurs first on the larger hygroscopic nuclei, if the available water vapour is not used up, supersaturation of the air increases and allows condensation to take place on smaller nuclei Thus, the rate at which the cloud grows is dependent on the rate of cooling of the air and the nature, numbers and sizes of the condensation nuclei present Differential equations have been set up and an electronic computer used to calculate the evolution of a population of cloud droplets Recent results have shown a resemblance between a theoretically produced drop size distribution and those which are actually observed

A typical cloud without rain formed over land contains a few hundred droplets per c c of air, but over the ocean there may only be a tenth of this number Typical droplet radii are 10μ

There are two mechanisms which bring about the growth of cloud droplets to the size of drizzle or raindrops The most recently established process explains the release of rain from clouds which are everywhere warmer than 0° C In the early days of cloud physics it was thought that rain could not fall from clouds unless their tops penetrated above the 0° C isotherm Later it was noticed that rain fell, particularly in the tropics, from clouds which were observed to be well above 0° C It was shown that cloud droplets exist in various sizes, because they form on condensation nuclei of different sizes, and grow under different conditions of temperature and supersaturation in different parts of the cloud A droplet which is larger than its neighbours will fall through them, and in doing so it may collide and coalesce with others lying in its way

A study of the coalescence process has been made by L M Hocking, of University College, London His theoretical computations inferred that cloud droplets of less than 19μ radius were unable to capture droplets of smaller size, so that their existing size must therefore be reached by condensation probably on large salt nuclei These theoretical calculations have been verified experimentally by laboratory results which agree with Hocking's values that droplets of radius less than 20μ do not take part in the coalescence process The problem of coalescence is being investigated further by a technique by means of which water is forced through a hypodermic needle which is attached to the diaphragm of an ordinary headphone The application of an audio-frequency signal of the right frequency causes the needle to vibrate and throw off a stream of drops The size and separation of the drops can be controlled Thus, the behaviour of streams of drops of different sizes may be examined through a microscope Collision is usually followed by coalescence, but sometimes the droplets rebound Behaviour of the droplets under an electric field is also being examined The introduction of an electric field assists coalescence

The second mechanism of precipitation release arises from the fact that cloud droplets exist in the supercooled state As the temperature in the ascending air cools below 0° C some of the droplets freeze In order to freeze at these temperatures they must become infected with special minute particles called ice nuclei It is not until the temperature reaches $-40°$ C or less that supercooled water droplets of a few μ freeze spontaneously Thus, as the temperature falls lower and lower below 0° C, more and more ice nuclei become active and more and more ice crystals appear among the supercooled water droplets In such a mixture of ice crystals and water droplets the saturation vapour pressure over the water droplets exceeds that over the ice crystals so that there is a vapour pressure gradient from the water droplets towards the ice crystals The ice crystals therefore grow much more rapidly than the droplets and soon reach a size sufficient to give them an appreciable falling speed In falling they may join together and form snowflakes which settle through the air in a tumbling motion until they reach warmer levels and melt into raindrops

Much of the work of Prof Mason and his group has been concerned with the basic physical processes of the ice-crystal mechanism of precipitation release Not the least of the questions involved is that of the freezing process itself Observations have been made of the freezing of a large number of drops of distilled water of diameters 10μ–1 cm at the interface of two immiscible liquids to avoid the nucleating effects caused by contact with solid surfaces Fig 1 shows the freezing temperature distribution about the most frequent value ($-24°$ C) of 1,100 such droplets of 1-mm diameter The curve shows that nucleation is

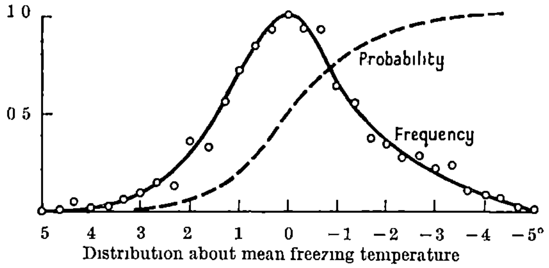

Fig 1 Distribution of freezing temperatures of 1,100 water drops of 1 mm diameter about the most frequent value of −24° C

a statistical process Mason and other workers have shown that there is a relationship characterizing the nucleation of water-drops containing small foreign particles This may be interpreted in terms of the fact that the numbers of particles which become active as ice nuclei in the atmosphere increase roughly logarithmically with decreasing temperature In experiments in which great care was taken to remove particles from the water it was possible to supercool large numbers of drops of diameter 1μ to −41° C and drops of diameter 1 mm to −33° C Such experiments suggest that groups of water molecules undergo random fluctuations of position and velocity, and become locked by chance into an ice-like arrangement to serve as nuclei to initiate freezing

The ice nuclei which initiate freezing of supercooled cloud droplets may be regarded as the fundamental particles of cloud physics Since 1 m^3 of air in the atmosphere may contain only 10 active ice nuclei among a population of 10^{11} other particles they are difficult to detect and identify One technique which has been used is to fill a cloud chamber with saturated air, chill it below 0° C, and then subject it to rapid expansion During the sudden cooling the supercooled droplets which contain active ice nuclei will freeze and grow into ice crystals These may then be counted for successively lower temperatures caused by successively greater expansions

Measurements made from aircraft over land and sea show a variable ice-nucleus population Down to about −30° C their concentration increases almost logarithmically with decreasing temperature, while below −35° C spontaneous nucleation causes a rapid increase in the number of crystals present The fact that the concentration of the nuclei appears to fall at times below the minimum value needed to release precipitation efficiently may be used as an argument for the belief that some additional precipitation may be produced by seeding clouds with artificial nuclei such as silver iodide

The nature and origin of ice nuclei are somewhat controversial Prof Mason believes their origin is the Earth's surface Dr E G Bowen, on the other hand, has suggested that meteoric showers may be an important source In an attempt to test these rival theories, laboratory experiments were conducted on various types of soil and mineral-dust particles, and also meteoric material, in order to test their ice-nucleating ability Of all these substances, the most abundant of the active particles was kaolinite, a minor constituent of the Earth's crust, which initiates ice formation at −9° C Dusts produced by grinding and vaporizing meteorites were not effective above −17° C Additional evidence from electron microscope and electron diffraction techniques in Japan has shown that 85 per cent of the identified particles were mineral, of which 80–90 per cent were clays, 50–60 per cent being kaolin

A search for substances which might be more effective than silver iodide for cloud-seeding purposes has not been successful Within the range −4° C to −11° C silver iodide, being more potent and more easily dispersed than its rivals, remains the best

Another problem in cloud physics which has attracted Prof Mason is that posed by the extraordinary variety of shape exhibited by natural snow crystals There are three main forms the hexagonal prismatic column, the thin hexagonal plate, and the branching star-shaped form The crystal form is related to both the temperature at which they form and the supersaturation of air Artificial crystals have been grown under controlled conditions in order to investigate the factors which influence the particular form they take Broadly speaking, the temperature governs the basic habits of the crystal, but supersaturation affects the speed of growth and the development of various secondary features Evidence is now accumulating which suggests explanations of the basic processes involved in crystal shape formation

The final topic on which Prof Mason touched was the generation of electricity by thunderstorms The thunderstorm may be regarded as an electrostatic generator in which the positive charge is concentrated in one region of the cloud and the negative charge in another C T R Wilson showed thirty years ago that the negative charge is centred in the lower part of the cloud where the temperature is about −5° C, while the positive charge is situated several km higher at temperatures usually below −20° C

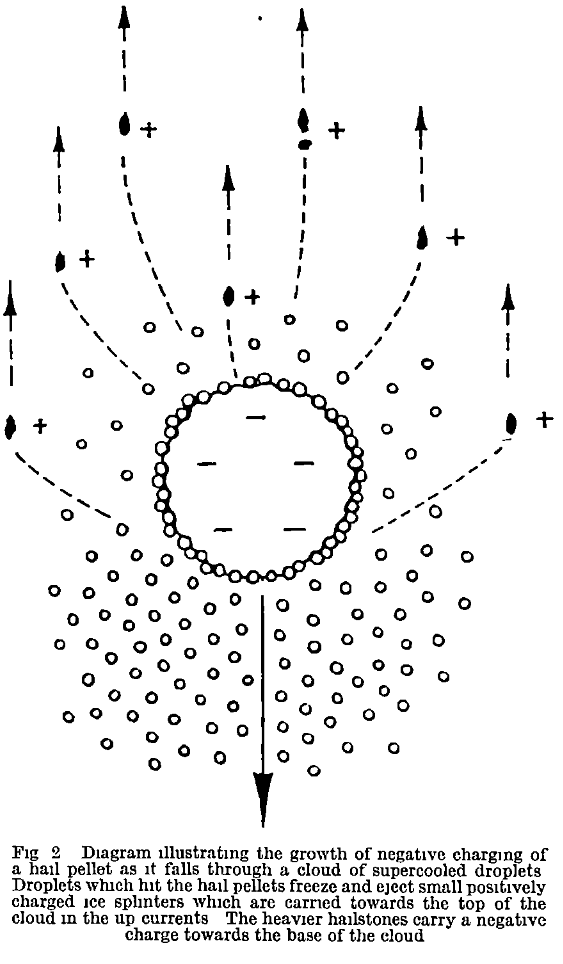

Fig 2 Diagram illustrating the growth of negative charging of a hail pellet as it falls through a cloud of supercooled droplets Droplets which hit the hail pellets freeze and eject small positively charged ice splinters which are carried towards the top of the cloud in the up currents The heavier hailstones carry a negative charge towards the base of the cloud

It has been calculated that the average rate of charge generation in a typical thunderstorm between the appearance of precipitation that is detectable by radar and the first lightning flash is about 1 coulomb/km.^{3}/min. Existing theories appear incapable of producing charge at such a rate. Prof. Mason's theory is that the formation of hail pellets in a cloud by the impaction and freezing of supercooled droplets leads to the formation of negatively charged hailstones which fall towards the base of the cloud. Meanwhile, positively charged ice splinters, formed by the bursting of the ice shell and the ejection of small ice splinters when drops of 0·03-mm.–1-mm. radius freeze, are carried by the up-currents towards the top of the cloud (Fig. 2). The electrification of artificial hailstones by the impaction, freezing and splintering of supercooled droplets has been examined in the laboratory by means of specially designed apparatus.

In a typical experiment at an air temperature of -15° C., droplets of 80μ diameter impacting at 10 m./sec. froze to produce, on average, twelve splinters and a charge of 4×10^{-6} E.S.U. per drop. These laboratory measurements lead to the conclusion that the charging of hailstones by the impaction, freezing and splintering of supercooled droplets is indeed capable of producing electric charge and electric fields at the rates required by observation, and that this is, in effect, the main mechanisms of thunderstorm electrification. It is further suggested that the large-scale generation of electricity in thunderstorms and the origin of lightning depend essentially on a thermo-electric property of ice, a preferential migration of protons under the influence of a temperature gradient which exists across the ice particles. This temperature gradient occurs because the outside of a supercooled water droplet freezes first and at a rate determined by the dissipation of the latent heat of fusion to the surroundings. The outside ice shell afterwards cools towards the lower air temperature, while the inner surface is at 0° C. Now protons tend to migrate down the temperature gradient, thus producing a positive space charge in the outer layers of the ice. When the ice droplet bursts by expansion of the freezing centre the splinters ejected from the outer layers will carry away a positive charge leaving the remainder negatively charged, as is observed.

Prof. Mason concluded his lecture by remarking that the subject of cloud physics was linked on the atomic and grand scales. Thus, the atmosphere sets the problem; this may be analysed in terms of basic physical processes which may be studied in the laboratory; finally, the pieces are put together back in their atmospheric setting. The past decade has seen considerable progress in our understanding of cloud- and rain-forming processes. All these problems will be investigated on a steadily expanding scale in the years ahead.

A. H. GORDON

A NEW RADIOHELIOGRAPH FOR AUSTRALIA

By DR. E. G. BOWEN

Chief of the Division of Radiophysics, Commonwealth Scientific
and Industrial Research Organization, Sydney

THE Ford Foundation has announced the grant of 550,000 dollars to the Radiophysics Division of the Australian Commonwealth Scientific and Industrial Research Organization for the construction of a radioheliograph for photographing the Sun in its natural radio emission (Fig. 1). The instrument represents the latest prospective addition to C.S.I.R.O.'s radio astronomical equipment and the announcement follows hard on the heels of the completion of the 210-ft. steerable radio telescope at Parkes in New South Wales. It is likely that the radioheliograph will be situated near the 210-ft. paraboloid; indeed, the two instruments will share facilities and will together form the nucleus of the Australian National Radio Astronomy Observatory which was inaugurated last year.

The function of the proposed instrument is to obtain high-resolution radio pictures of the Sun, at wave-lengths near 3·5 m., at regular intervals of time varying between seconds and minutes depending on the phenomena being recorded. The angular size of each complete picture will be 2°, and the angular resolution within this field will be equivalent to a 60-line television picture. It is designed to record both the evolution of solar bursts, such as those which accompany solar flares, and the general structure of the thermal corona.

During the post-war years, C.S.I.R.O. radio astronomers, under the leadership of Dr. J. L. Pawsey, have been actively engaged in research on solar radio emission. In particular, observations in the metre-wave spectrum have been made by J. P. Wild and his colleagues with radio spectrographs and interferometers; these have not only contributed significantly towards an understanding of the basic processes occurring in the Sun's corona at the time of flares, and of the solar–terrestrial relationships, but have also posed many new questions associated with the coronal plasma. But such studies have lacked comprehensive positional data, and the new project, designed to fill this gap, represents the next logical step in the Division's solar programme.

The instrument, which will operate at a wave-length near 3·5 m., is designed to scan the Sun rapidly with a pencil beam of reception of angular size 3·5 min. of arc between points of half-power. This will be accomplished with the use of 100 paraboloid aerials, each 42 ft. in diameter, arranged around the perimeter of an ellipse of minor axis (east–west) of 3 km. and major axis (north–south) of 3·6 km. These dimensions are so chosen as to make the resolving power of the instrument equivalent to that of a uniform circular aperture of diameter 3 km. when viewed from the direction of the Sun at noon at equinox.

Signals from the aerial elements will be taken along open-wire feeders to a central station at the southern focus of the ellipse, where they will be combined in a multiplicity of phase relationships to form the final picture on a cathode-ray tube. The sensitivity of the equipment will be enhanced by the use

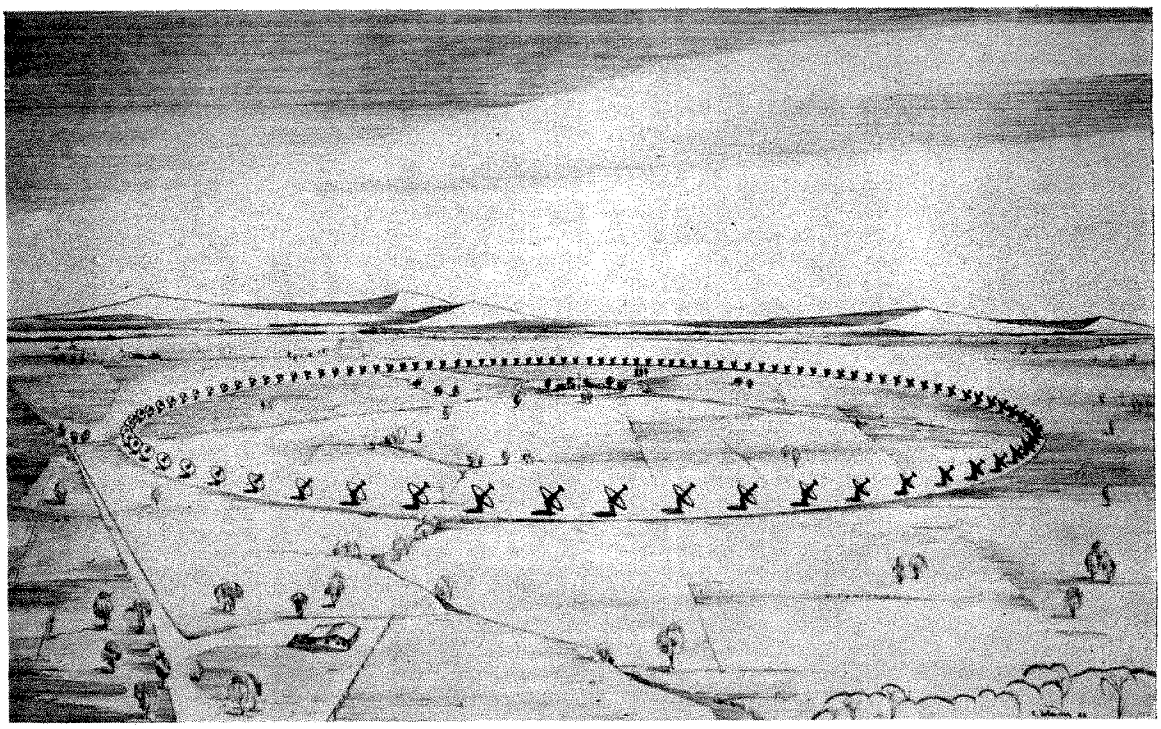

Fig. 1. Artist's impression of the proposed radioheliograph. The aerial array consists of a hundred 42-ft. paraboloids around the perimeter of an ellipse with major and minor axes of length 3·6 and 3·0 km. respectively

of 50 separate detectors, thus allowing the instrument to look in 50 different directions, along a north–south line, at the same time. The picture will be formed by sweeping these 50 beams across the face of the Sun in the east–west direction. A special post-detector computer will be incorporated to perform the process of aerial correction[1] required to make the thin annular aerial array equivalent to a full aperture.

The design and scientific direction of the project are being undertaken by Mr. J. P. Wild, who is in charge of the Division's programme of solar research. The generous grant of the Ford Foundation will enable constructional plans to proceed immediately, and it is hoped that the instrument will be ready for operation in about three years time, near the start of the next solar cycle.

---

NEWS and VIEWS

Chemistry at York : Dr. R. O. C. Norman

DR. R. O. C. NORMAN, whose appointment, as from 1965, as professor of chemistry in the new University at York, has recently been announced, is just thirty. He was educated at St. Paul's School, London, and Balliol College, Oxford, where he was a Brackenbury scholar. At Oxford he was the Gibbs scholar in chemistry of his year and gained first-class honours in 1955. In 1956 he was elected to a junior research fellowship at Merton College, where two years later he was appointed as tutorial fellow in organic chemistry and has, since 1960, been acting as dean. Dr. Norman's research work for his D.Phil. degree was carried out under the supervision of Dr. W. A. Waters and dealt with aspects of homolytic substitution of polycyclic aromatic compounds. Since 1958 Dr. Norman has been directing the activities of an independent research group in the Dyson Perrins Laboratory which has substantially contributed accurate quantitative data concerning heterolytic substitution of benzene derivatives, making use of a sensitive technique of vapour phase chromatography which was developed in conjunction with his Merton colleague, Dr. C. S. G. Phillips. From this work Dr. Norman and his students have been able to put forward new quantitative theories concerning rates of aromatic substitution and the puzzling problem of the *ortho/para* ratio: for this Dr. Norman was this year awarded the Meldola Medal.

The importance of quantitative aspects of organic chemistry is year by year becoming more evident, and since it requires co-ordination both with the latest of analytical techniques and with basic physico-chemical theories, it could be an excellent basis for the development of a new school of chemistry in Britain. The University of York has clearly chosen a man with youthful vigour and research enthusiasm, supported by experience of the tutorial approach to undergraduates which gives them the close personal contacts and stimulations that have proved to be so valuable in the older universities.

Chemistry in the University of East Anglia : Dr. A. R. Katritzky

DR. ALAN ROY KATRITZKY, who has recently been appointed to the chair of chemistry in the new University of East Anglia, was born in London, where he received his early schooling, and then, after national service in the Royal Air Force, entered the University of Oxford in 1948 as a member of St Catherine's Society to read chemistry He took his B A degree with first-class honours, and then the B Sc and D Phil degrees after research with the late Dr S G P Plant and Sir Robert Robinson, respectively He was appointed an Imperial Chemical Industries Fellow and later a lecturer and tutor at Pembroke College In 1958 he was appointed a University demonstrator at Cambridge, and a year later an Official Fellow and director of studies in chemistry at Churchill College Dr Katritzky's research has been mainly in heterocyclic chemistry, where he has been engaged in particular in the application of physical methods, especially infra-red, ultra-violet and nuclear magnetic resonance spectroscopy, to the study of the structure, tautomerism and reaction mechanisms of various heterocyclic systems He is also well known for his text-book, *Heterocyclic Chemistry* (with Mrs J M Lagowski), which appeared in 1960 and contains a very considerable mass of material in a comparatively slender volume At the age of thirty-three he has about a hundred published research papers and in addition to the above text-book has other books, written or edited, in the press He is the senior editor of the English translation of *Russian Chemical Reviews*

Metallurgy at the Manchester College of Science and Technology

Prof K M. Entwistle

Dr Kenneth Mercer Entwistle has been appointed to a newly created chair in metallurgy by the Councils of the University of Manchester and the Manchester College of Science and Technology Dr Entwistle, who is thirty-seven years of age, was educated at Urmston Grammar School, Manchester, and at the University of Manchester, where he graduated with honours in electrical engineering in January 1945 He was awarded the degree of M Sc in December 1945 and after postgraduate research in the Department of Metallurgy was appointed assistant lecturer in metallurgy in the University of Manchester in October 1947 He was awarded the degree of Ph D in July 1948 He became lecturer in metallurgy in October 1949, senior lecturer in metallurgy in October 1954, and reader in metallurgy in October 1960 He has been a member of the United Kingdom Group at the World Metallurgical Congress, Detroit (1951), and was British Council visiting lecturer at the Bergakademie, Clausthal-Zellerfeld, West Germany, for two weeks in 1954 He is a past-president of the Manchester Metallurgical Society Dr Entwistle will take up his new appointment on September 1

Biochemistry at Queensland

Prof E C Webb

At the age of forty-one, Dr E C Webb has been appointed the first professor of biochemistry in the University of Queensland, Brisbane, Australia, and will take up his duties there in August Dr Webb was born in Dorset and educated at Poole Grammar School and Clare College, Cambridge He went to Clare College in 1939 to read science and was placed in the First Class in both parts of the Natural Sciences Tripos, with biochemistry as the subject for Part II From 1942 until 1944 he engaged in extra-mural research at Cambridge for the Ministry of Supply, which related to the mechanism of action of the so-called nerve poisons This was carried out in collaboration with Dr Malcolm Dixon, with whom he has remained in close partnership ever since From 1944 until 1946 Dr Webb held a Beit Memorial Fellowship for Medical Research and then was appointed successively demonstrator, and lecturer, in biochemistry in the University of Cambridge His research work has been particularly concerned with the isolation of enzymes and the study of their kinetics and specificity of action He was co-author with Dr Malcolm Dixon of the monumental book on *Enzymes* published in 1958 Dr Webb has been a member of the Commission on Enzyme Nomenclature set up by the International Union of Biochemistry, and is secretary of the Standing Committee which keeps the subject of enzyme nomenclature under review He was formerly a member of the Cambridgeshire County Council, and for twelve years has been a member of the Board of Governors of the United Cambridge Hospitals He has also served as a member of the Governing Bodies of the Cambridge Technical College, of the Perse School for Girls and of the Perse School for Boys Dr Webb goes to Brisbane with a firmly established scientific reputation, wide experience of university teaching and good experience of administrative matters

Unit Cost of Nuclear Power Production

In a written statement circulated with the official report on July 16, the Parliamentary Secretary to the Ministry of Power, Mr J Peyton, gave the following estimated total costs of generation at nuclear power stations, 1962–66 Berkeley, 1 05*d* per unit, Bradwell, 0 95*d* , Hinckley Point, 0 85*d* ; Trawsfynydd, 0 81*d* , Dungeness, 0 66*d* , Sizewell, 0 66*d* , Oldbury, 0 66*d* The average cost of generation at conventional stations in 1960–61 was 0 88*d* per unit, and varied from an estimated 0 55–0 7*d* for plant commissioned in 1962 to about 0 5–0 65*d* for plant commissioned in 1960

British Manpower in Countries now Independent

In a written answer in the House of Commons on July 26, the Secretary for Technical Co-operation, Mr D Vosper, gave the number of pensionable British expatriate officers now serving in Ghana as 30 compared with 580 at the time when that country gained independence For Sierra Leone the corresponding figures are 115 and 250, and for Nigeria Federation, 555 and 870, North, 640 and 900, East, 90 and 105, West, 110 and 135 Mr Vosper had no firm figures of contract officers

British Assistance to Latin America

In replying for the Government to a debate on the international situation in the House of Lords on July 25, the Minister of State for Foreign Affairs, the Earl of Dundee, said that while Lord Lindgren had criticized, perhaps justly, certain features of the execution of American aid in Latin America, he thought that President Kennedy's plan of massive aid to South American countries towards economic progress with liberty, "The Alliance for Progress", was one of the greatest and most imaginative projects of this century Moreover, Britain would wish to help as much as her balance of payments allowed In recent years, Britain had greatly expanded her cultural and information efforts in Latin America, and lately a plan had been started for technical assistance now costing £70,000–£80,000 a year What the South Americans perhaps needed most was the expert technical knowledge to use their resources Together with the University Grants Committee, Britain had also been considering ways and means of expanding the scope of Latin American studies in British universities, and it was hoped to announce a practical first step towards this end in the autumn

Medical Research Council Vision Research Unit

THE Medical Research Council have announced that, on the assumption of financial responsibility for the major part of the work of their Ophthalmological Research Unit by the University of London from August 1, the Unit's Visual Research Division will be reconstituted as a separate Council Unit under the direction of Dr H J A Dartnall, at present head of the Council's Visual Research Division It will be known as the Vision Research Unit and will continue to be housed in the Institute of Ophthalmology, Judd Street, London, W C 1

Supply of Science Teachers

A REPORT entitled *The Supply of Science Teachers in England and Wales* by the Joint Committee for Science and Education (Pp 19 London Joint Committee for Science and Education, 15 Half Moon Street, 1962 1*s*) states that, immediately, there is need for an increase of between 28,000 and 34,000 over the present number of graduate science teachers in schools, technical colleges, training colleges and universities, which stands to-day at about 20,600 In addition, the report states that an increase of 12,000–18,000 non-graduate specialists in science teaching will be needed in schools The shortage of science teachers is seen to be one part of the general teacher shortage, but many reasons are given for regarding it as a separate and specially urgent problem The present and future supply of mathematics teachers is an equally grave problem The whole education system, and not only science teaching, will suffer without an adequate supply of mathematics teachers But, in the Committee's view, the supply of mathematics and of science teachers presents two distinct problems The sooner this is accepted, "the sooner will policies be forthcoming which are adequate to the solution of both problems" There is a general awareness of the increasingly urgent need for more scientists and technologists in industry and the public services This report emphasizes the need to consider not only the training of these specialists but also the training of non-specialists "We need not only more specialists We need a common culture which includes more science To achieve this we must foresee science being taught to all children throughout their school lives "

Science Laboratories in Grammar Schools

Provision and Maintenance of Laboratories in Grammar Schools (1961) is the title of a report compiled from 762 answers to a questionnaire sent to grammar schools in England and Wales (Pp 16 London John Murray Published for the Science Masters' Association, 1962 2*s* net) The object of the survey, the third of its kind, was to find out whether laboratory facilities in schools were satisfactory and, if not, in what respects they were unsatisfactory. The report compares existing facilities, first, with the standards recommended by the Ministry of Education and, secondly, with the standards recommended by the Industrial Fund for the Advancement of Scientific Education in Schools Compared with 1959, there has been an increase from 45 to 55 per cent in the number of local education authority schools which have, according to Ministry of Education standards, adequate laboratories Local education authority schools, however, still lag behind direct grant and independent schools More local education authority schools now employ one or more laboratory technicians, but only 8 per cent of these schools employ a sufficient number of technicians In many cases the local authority makes no provision for such assistance, and the report stresses the importance of adequate technical assistance in the teaching of science Laboratory finance is expressed as the amount spent per annum per pupil taking science—the minimum sum regarded as adequate being 12*s* 6*d* Local education authority schools for boys spend on the average 13*s* 6*d* , compared with 12*s* 3*d* in 1959 The report points out that 50 per cent of these schools spend less than 12*s* 6*d* per annum per child, which is not adequate Girls' schools, particularly, have inadequate facilities for teaching science, as well as suffering from an acute shortage of science teachers Mixed schools, in general, lie between boys' and girls' schools, while the laboratory facilities in comprehensive and bilateral schools vary considerably

Bulletin of the Royal Society International Scientific Information Services

THE Royal Society has established a special library for the publications of the International Council of Scientific Unions, the International Scientific Unions, Commissions, Special Committees and Permanent Services, as well as of certain other publications such as those of the United Nations Educational, Scientific and Cultural Organization in the Arid Zone, Humid Tropics and Marine Sciences With this library as a basis, it is planned to provide an information service to facilitate use in the United Kingdom of the international contacts of the Royal Society The first issue of the *Bulletin of the Royal Society International Scientific Information Services*, which it is proposed will be published regularly, has become available (1, No 1, July 1962 Pp 80 London The Royal Society, 1962) It contains complete lists of the holdings of the Society, arranged under the International Council and under the different International Unions or other bodies responsible for publication Future issues will keep the catalogue up to date, and in his preface Sir Patrick Linstead expresses the hope that the *Bulletin* will keep scientists in touch with international developments It is also proposed to include occasional articles on international scientific affairs and notes on exchanges, visits, grants and similar matters The first issue is well produced and admirably designed for its task of making these scientific publications more widely known

The British Journal for the History of Science

SHORTLY after the British Society for the History of Science was formed in 1947 it produced a *Bulletin* which, owing to the stringency of the times, was virtually a broad-sheet Later, by arrangement, the *Bulletin* was published as a supplement to the *Annals of Science*, with Dr N H de V Heathcote as a connecting link between both journals, being editor of one and on the editorial board of the other Yet even this arrangement had its difficulties, as papers read to the Society could not be published *in extenso* Now, however, a major step forward has been taken with the issue of *The British Journal for the History of Science*, 1, Part 1, No 1, June 1962 Pp 95 (Published twice annually Ravensmead, Keston, Kent The British Society for the History of Science, 1962

15*s* per part) Under the editorship of Dr H D Anthony, it offers five papers, all read to the Society Dr J S Wilkie, on "Some Reasons for the Rediscovery and Appreciation of Mendel's Work in the First Years of the Present Century", Dr C H Talbot, on "Simon Bredon, Fellow of Merton, Mathematician, Astronomer and Physician", E A Marland, on "British and American Contributions to Electrical Communications", Thomas Martin, on "The Origins of the Royal Institution", Leonard Clarke, on "Greek Astronomy and its Debt to the Babylonians" There is a précis of four other lectures, together with a useful bibliographical note on papers in other journals and a book review As a journal it should be widely used in universities and technical colleges

Natural Resources in Scotland

A REVIEW of the volume entitled *Natural Resources in Scotland*, which recorded the proceedings of the symposium organized by the Committee on Natural Resources of the Scottish Council during October 31–November 2, 1960, has already appeared in *Nature* (193, 514, 1962) The Committee has now issued its report as a cyclostyled foolscap-sized document, adopted by the Scottish Council (Development and Industry) It is based on the evidence presented to the symposium, which was studied and carefully sifted by seven working parties The lack of accurate factual information is again emphasized, and the report calls for detailed surveys as a pre-requisite for planning The keynote of the thirteen-point plan is the need for integration—notably of farming and forestry—and for the multiple use of land with the over-riding objective of maintaining and increasing the productive capacity of the land Copies of the report are available from the Council, price 21*s* (Pp v+194 Edinburgh The Scottish Council (Development and Industry), 1962)

Strontium-90 in Human Bone

No 4 of the *Medical Research Council Monitoring Report Series* contains initial analyses of strontium-90 in human bone for the first half of 1961 The analyses were carried out by the Atomic Research Establishment and by research workers in Glasgow The results indicate that, for most age groups, the average amounts of strontium-90 in bone during the first half of 1961 were approximately the same as in the second half of 1960, but for the important age group of 0–5 years the analyses made at the Atomic Energy Research Establishment show a decrease in the average level from 2 65 to 2 07 strontium units (micro-microcuries of strontium-90 per gram of calcium) The highest single value recorded in the United Kingdom during the first half of 1961 was 6 5 strontium units The period covered by this report precedes the resumption of nuclear weapon testing in the autumn of 1961

Expedition to Iceland

A CHELSEA College expedition to Iceland was first suggested in 1956 by David Bellamy, then a student in the Department of Botany and Zoology Bellamy's suggestion was not followed up, however, until the summer of 1960, when W A Stevens initiated the planning of the College's first scientific expedition Seven students took part in the expedition, which lasted two months and was centred on the Baegista Valley in the north of Iceland a report of the expedition has now been published (Chelsea College Union *Biological and Geological Societies' Expedition to Iceland, Summer 1961—Final Report* Pp 52 London Chelsea College Iceland Expedition, 1962 3*s* 6*d*) The purpose was to make detailed botanical surveys and geological maps of the area visited, to correlate botanical and geological studies so far as possible, to make comprehensive collections and records of the plants, rocks and minerals found, to examine the more interesting, instructive or natural sights of Iceland, including the volcanic thermal and glacial phenomena, to make ornithological observations where possible, and to learn as much as possible about the Icelandic countryside and nation The illustrated report gives full details of the expedition and could be of great value to other students planning to make surveys in various countries overseas

Chemotherapy of Cancer

DIFFERENT people may hold different views on the political side of the United Nations, but no reasonable person can deny a great belief in, and his full support of, the admirable work of the United Nations' welfare, medical, scientific and cultural organizations One of these bodies is the World Health Organization with its headquarters in Geneva It is very gratifying to find that its efficient staff have turned their attention recently also to the chemotherapy of cancer (which includes leukæmias), and with the help of a panel of experts have issued their first report on this subject (*Technical Report Series* No 232 *Chemotherapy of Cancer* First Report of an Expert Committee Pp 52 Geneva World Health Organization, London H M S O, 1962 2 Swiss francs, 3*s* 6*d* , 0 60 dollar) It is true that so far as this report represents a critical assessment of the present situation in this field by enumerating the general principles of cancer chemotherapy and making a review of available and tested agents, other publications have appeared from time to time written by individuals or co-operative groups However, as the report is also looking forward and touches on topics such as combined treatments and on the intricate problem of chemical trials of new drugs, the Expert Committee, and particularly its secretaries, Drs A V Chaklin, W Davis and Prof L F Larionov, should be congratulated on a fine piece of work This will be most useful to the investigator, scientific or medical, in cancer chemotherapy and also to anybody interested in any form of medical science as applied to the treatment of pathological states

Society for Applied Bacteriology

AT the annual meeting of the Society for Applied Bacteriology, held in Sutton Bonington on July 17, the following were elected officers of the Society *Honorary President,* Dr T Gibson, *Honorary Secretary,* Dr Ella M Barnes, *Honorary Treasurer,* Mr G Ellis Jones, *Honorary Editors,* Dr S E Jacobs and Dr D J Jayne-Williams, *Honorary Publications Manager,* Mr A H Walters, *Honorary Advertising Manager,* Mr E J Mann, *Members of the Committee,* Dr A Hurst, Dr N D Harris, Dr J G Murray, Dr J R Norris, Dr A M Paton, Dr Joan Taylor, Dr Agnes A Nichols, Dr Patricia M Scholes, Dr A Seaman, Mr G Sykes (*ex-officio*)

Stability of Vitamin Preparations

A COLLABORATIVE investigation into the stability of seven vitamins (ascorbic acid, cyanocobalamin, folic acid, nicotinic acid, nicotinamide, riboflavin and thiamine hydrochloride) during two years storage of different preparations has been initiated in India (Government of India Ministry of Health Report of the Central Drugs Laboratory, April 1958 to March 1959 By Dr H K Banerjee Pp ii+56 Delhi Manager of Publications, 1961 Rs 11 50 nP , 18*s*) The collaborators are the Central Drugs Laboratory, Calcutta, the Haffkine Institute, Bombay, and the Defence Research Laboratory (Stores), Kanpur Results from the different centres will be co-ordinated and statistically analysed in the Central Drugs Laboratory For experimental investigations, the pure vitamins were obtained from Hoffmann-LaRoche, Basle (except for cyanocobalamin, which was obtained from Glaxo Laboratories, Ltd) The physical and chemical characteristics of the products were tested in the Biochemistry Department of the Central Drugs Laboratory and, finally, ten pharmacopœial preparations were chosen for collaborative investigations on the stability of the preparations when stored under prevailing conditions of temperature and humidity in Calcutta, Bombay and Kanpur The preparations are (1) ascorbic acid tablets, coated (25 mg/tablets), (2) ascorbic acid tablets, uncoated (25 mg/tablets), (3) nicotinamide tablets (50 mg/tablets), (4) nicotinic acid tablets (50 mg/tablets), (5) riboflavin tablets (1 mg/tablets), (6) vitamin B_1 tablets (5 mg/tablets), (7) folic acid tablets (5 mg/tablets), (8) vitamin B_1 injection (25 mg/ml) (9) nicotinamide injection (50 mg/ml), (10) cyanocobalamin injection (50 µg/ml). The preparations were distributed to the collaborators towards the end of March 1959 for the assay of the initial content of the vitamin in each of the preparations at the three centres Thereafter, the vitamin content was determined at intervals of three months for a period of twenty-four months

Antibody to Enzymes—a Three-Component System

A MEETING on "Antibody to Enzymes—a Three-Component System" is to be held in New York during September 5–7, and will deal with the following topics *Section* 1, aspects of two-component immunology, *Section* 2, reaction mechanisms of the interaction of enzymes, antibody and substrate, *Section* 3, the effect of antibody on various enzymes, *Section* 4, interaction of enzyme, co-enzyme and substrate with antibody (*a*) reaction mechanism, (*b*) multiple forms of enzymes, *Section* 5, use of antibodies in the discrimination of multiple molecular forms of enzymes, *Section* 6, antibodies as tools in studies of biosynthesis of enzymes The meeting is being held under the auspices of the New York Academy of Sciences and will draw its speakers from Australia, Britain, Canada, France and the United States Further information can be obtained from Dr B Cinader, University of Toronto, Department of Medical Biophysics, 500 Sherbourne Street, Toronto 5

The Tenth International Botanical Congress

THE first circular giving general information about the forthcoming Tenth International Botanical Congress, to be held in Edinburgh from August 3–12, 1964, has now been issued to some 9,000 botanists and botanical institutions throughout the world The majority of recipients are those who have attended previous Congresses, but it is believed that there may be quite a number of botanists who would wish to have a copy of this circular and who have not yet received one These may be obtained on request from the Secretary (Executive Committee), Tenth International Botanical Congress, 5 Hope Park Square, Edinburgh, 8 Enclosed within the circular is a preliminary registration form which is to be returned before September 30, 1962, by those interested in the Congress Subsequent Congress circulars and registration forms will be distributed only to those who complete one of these preliminary registration forms

Physiology and Psychology of Arid Lands

IN *Nature* of July 21, p 232, it was announced that a symposium on "Environmental Physiology and Psychology in Arid Conditions", being organized by Unesco. was to be held in Naini Tal, India, during August 27–September 1 It has now been announced by the Department of Natural Sciences of Unesco that for various reasons the date and venue for this symposium have been changed it will be held at the Central Drug Research Institute, Lucknow, India, during December 7–12

Conference on Palæoclimates

A CONFERENCE on "Palæoclimates", sponsored under the Nato Advanced Institute programme, will be held in the Physics Department, King's College, Newcastle upon Tyne, during January 7–11, 1963 The subjects to be covered range from palæobotanical and palæontological inferences on climate to the information gained from the rocks themselves, evaporites, glacial deposits, limestones, etc Supplementary information from geophysics will also be introduced The aim of the meeting is to stimulate research, consequently the accent will be on the problems of palæoclimates rather than on results Although it is intended to limit the number of participants, it is still possible to extend invitations to research workers and postgraduate students with an active interest in the subject Some financial assistance may be available for students Further information can be obtained from the Administrative Assistant, Department of Physics, King's College, Newcastle upon Tyne, 1

The Field Survey Association Annual Prize, 1962

THE Field Survey Association is offering a prize of £50 for the best paper on a surveying subject, consistent with their aims and objects, submitted before December 31, 1962, provided that this paper is considered to be of sufficient merit for the award of the prize The prize is open to any person under the age of thirty-five on December 31, 1962, who may be either within or outside the membership of the Association, but those outside must be eligible for membership The rules of the prize, the history and objects of the Association and the conditions of membership can be obtained from the honorary secretary of the Award Committee, Commander R Bill, Vickers House, Broadway, S W 1

The Beilby Medal and Prize, 1963

AWARDS from the Sir George Beilby Memorial Fund are made by the Administrators of the Fund, representing the Royal Institute of Chemistry, the Society of Chemical Industry and the Institute of Metals Sir George Beilby had been president of each of these three bodies, and they jointly sponsored the appeal for subscriptions whereby the Fund was raised as a memorial to him after his death in 1925 The Beilby Medal and Prize, consisting of a gold medal and a substantial sum of money, is specified as being 'For Advancement in Science and Practice' Such an award is offered at intervals of two years, but more than one may be made on the same occasion if there are several candidates of sufficiently outstanding merit The awards are made to British scientists in recognition of independent original work of exceptional merit, carried out continuously over a period of years and involving the development and application of scientific principles in any field related to the special interests of Sir George Beilby, namely, chemical engineering, fuel technology or metallurgy, in their modern interpretations The awards are intended as an encouragement to men and women (preferably under the age of forty) who have carried out work of practical significance in any of these fields Consideration is to be given to the making of an award from the Fund in 1963 Outstanding work of the nature indicated may be brought to the notice of the Administrators, either by persons who desire to recommend the candidate or by the candidate himself, not later than December 31, by letter addressed to the Convener of the Administrators, Sir George Beilby Memorial Fund, the Royal Institute of Chemistry, 30 Russell Square, London, W C 1

The Night Sky in September

FULL moon occurs on Sept 14d 04h 12m U T and new moon on Sept 28d 19h 40m The following conjunctions with the Moon take place Sept 1d 05h, Mercury 6° S, Sept 3d 02h, Venus 8° S, Sept 11d 03h, Saturn 1° S, Sept 13d 04h, Jupiter 1° N, Sept 19d 12h, Aldebaran 1° S, Sept 22d. 13h, Mars 2° N In addition to these conjunctions with the Moon, Mars is in conjunction with Pollux on Sept 30d 13h, Mars being 6° S Mercury is too close to the Sun for observation Venus is an evening star, visible low in the west after sunset Mars rises at 23h 30m, 23h 10m and 22h 55m on Sept 1, 15 and 30, respectively It is at a distance of 148 million miles on September 15, and its stellar magnitude is +1 2 Jupiter sets at 5h 15m, 4h 10m and 3h 05m at the beginning, middle and end of the month, respectively It is in Aquarius, its stellar magnitude is −2 4 and its distance from the Earth in the middle of the month is 373 million miles Saturn is in Capricornus, setting at 2h 10m, 1 h 05m and 0h 05m on Sept 1, 15 and 30, respectively Its stellar magnitude is +0 6 and its distance from the Earth in the middle of the month is 858 million miles Occultations of stars brighter than magnitude 6 are as follows, observations being made at Greenwich Sept 17d 23h 01 5m, +11° 445 (*R*); Sept 21d 00h 18 7m, 64 Ori (*R*) *R* refers to reappearance The autumnal equinox occurs on Sept 23d 12h

University News: Edinburgh

THE following appointments to lectureships have been announced J Hogg (biophysics), Dr G S G Beveridge (chemical technology), A W Read (chemistry); R P Kirby (geography), C J Shaddock and Captain E T W Smyth (mathematics), Dr B L Ginsborg (electropharmacology), Miss Sybil M Lloyd (physiology)

Sheffield

DR B A BILBY, at present reader in theoretical metallurgy, has been appointed to the chair of theoretical metallurgy, as from October 1 Dr Bilby was the Sorby Research Fellow of the Royal Society in the University from 1951 until 1957

Southampton

DR K A MUNDAY, senior lecturer and head of the Department of Physiology and Biochemistry in the University, has been appointed to the newly established chair of physiology and biochemistry, with effect from October 1

Yale

A NEW Department of Biology has been established through the fusion of the former Departments of Botany and Zoology Prof D F Poulson, professor of biology, has been appointed chairman and director of biological laboratories Prof G E Hutchinson, Sterling professor of zoology, will serve as director of graduate studies Six major scientific fields are represented in the new Department genetics and cytology, developmental biology, physiology and biochemistry, comparative physiology and behaviour, ecology, and evolution and systematics The Department is at present housed in the Osborn Memorial Laboratories and occupies five floors in one wing of the Josiah Willard Gibbs Research Laboratories New facilities for research in experimental biology, to be housed in a central building of the new Kline Science Center, are in an advanced stage of planning

Announcements

PROF K C DUNHAM, professor of geology in the University of Durham, has been elected president of the Institution of Mining and Metallurgy for the session 1963–64 Prof Dunham was elected to membership of the Institution in 1941 He has served continuously as a Member of Council since 1950, holding office as a vice-president for the three sessions 1957–60

THE Society of Environmental Engineers will be holding the first meeting in its winter programme at the Imperial College of Science and Technology, Exhibition Road, London, S W 7, on September 12 Mr Russell Lowe, vice-president of the Barry Wright Corporation of Glendale, California, will speak on structural damping allied to the isolation of electronic equipment Further information can be obtained from the Society of Environmental Engineers, Suite 7, 167 Victoria Street, London, S W 1

THE Basic Science Section of the British Ceramic Society is holding a meeting on "Mechanical Properties of Non-Metallic Crystals and Polycrystals" at Hastings during October 16–17 Further information can be obtained from Dr J P Roberts (Honorary Section Secretary), Houldsworth School of Applied Science, the University, Leeds 2

A CONFERENCE on "Fœtal and Infant Liver Function and Structure", sponsored by the New York Academy of Science, is to be held during November 7–10 Further information can be obtained from Dr J A Sterling, 1351 W Tabor Road, Philadelphia 41, Pa

ERRATUM Mr Dhruba K Sen regrets that in his article entitled "Role of Carbonyl Chloride in the Production of Uræmia", which appeared on p 889 of the March 3 issue of *Nature*, paragraph 11, line 13 should read " *p*-dimethyl aminobenzaldehyde " instead of "*p*-diethyl aminobenzaldehyde"

IRRIGATION IN GREAT BRITAIN

THE water supply problem created by the spread of irrigation in Great Britain has already attracted the attention of the Central Advisory Water Committee of the Ministry of Housing and Local Government A preliminary study was undertaken by the Sub-Committee on the Growing Demand for Water and forms the subject of the committee's second report issued in 1960 It was, however, a very brief document of two pages, the first detailed and objective study of irrigation in Great Britain in which practically all aspects have been covered has been prepared and recently published as a report of the Natural Resources (Technical) Committee of the Office of the Minister for Science[1] It is a notable document which casts considerable light on a significant agricultural trend about which few quantitative data have hitherto existed

The report, prepared by a strong sub-section of the Committee on Agriculture, examines the possibilities and consequences of irrigation in Great Britain It brings together a considerable range of available information on crop responses, costs and returns, and assesses the likely value of irrigation to the farmer and to the community Tentative estimates are also made of the potential demands for water for irrigation.

It is quite clear from the report that irrigation of certain crops in parts of Britain can lead to a major increase in productivity With the continued loss of agricultural land to housing, industrial and amenity uses, and the need to produce at home the major portion of the food for the inhabitants of these islands, the extension of irrigation in the right areas could become a significant factor in promoting economic recovery coupled with an increasing standard of living The main problem is, of course, the need to provide the water in the right place at the right time

The area where irrigation can be utilized to increase output, reduce unit costs and improve efficiency of production is very largely that part of England receiving less than 35 in, together with that part of Scotland receiving less than 30 in, of rain a year The frequency of the need is greatest in the south and east, being about nine years in ten in the Thames Estuary and diminishing north and westwards towards the higher rainfall areas In most years up to 4 in of rain would be needed to make good the shortage At present some 130,000 acres of land are irrigated, and this is increasing by about 15,000 acres per annum If expansion continued at this rate some half a million acres might be subject to irrigation by 1980 The application of 4 in of water to this area would, according to the Natural Resources Report, require 50,000 million gallons Rough estimates of the eventual practical limits suggest an area of 1½ million acres with a peak annual demand of well over 100,000 million gallons This represents a possible peak daily demand for water ranging from about 2,000 million gallons a day in April and September to 3,000 million gallons a day from mid-June to early August This is in excess of the total amount of water at present being supplied throughout the country by all statutory water undertakers

The water so far used in irrigation has been obtained from a variety of sources of supply, and increasing competition with other users has raised many problems The irrigation demand varies considerably and reaches its maximum when supplies are often at their lowest It is clear that substantial expansion in irrigation will only be possible by increased conservation, mainly by storage of excess winter flow The report considers the ways and means whereby this can be most effectively undertaken and suggests in the first instance the extension of farm conservation schemes by means of storage reservoirs More than 250 of these have already appeared in the past year or two Eventually, however, the problem can only be solved by the transfer of surplus water from the wetter highland zone of Britain to the drier lowland zone

At present the water is largely applied by overhead spray methods To be effective the farmer needs to know when to spray and how much to apply The report details the technique which has evolved so far Some interesting figures are also given for the likely return in both production and value Maincrop potatoes receiving about 4 in of water may give an increased yield of 3 tons per acre, valued at about £50, cauliflowers, receiving 2 in, an increase of 3 tons, valued at up to £150, soft fruits, receiving 2–4 in of water, an increase of yield of from 20 to 50 per cent valued at between £50 and £100 per acre Grass may give an increased return of about £20 per acre from 5 in of water, but here the cost of the water becomes critical

The actual costs of the irrigation vary according to the availability of water and equipment For the now almost standard overhead spray method capital costs come out at about £25 per acre Where water is 'free' running costs plus depreciation and interest may average out at 45*s* per acre-in of water for an application of 3 in The detailed economics of irrigation have yet to be worked out, however But it is quite clear that the method pays dividends almost everywhere with vegetables, fruit, potatoes and peas, but that it might be marginal with grass, sugar-beet, field beans and cereals

The Committee comes, without difficulty, to the conclusion that the judicious use of irrigation in agriculture and horticulture should be encouraged It recommends that active steps should be taken to improve conservation of water, especially by local storage in small units close to the land to be irrigated In the larger sphere conservation works should be properly planned in relation to each other and in conjunction with the proper development of the water resources of a particular river basin Demands for water for irrigation should, it is thought, be considered together with demands for water for industrial purposes Further research is also considered desirable on the fundamental, technical and operational aspects of irrigation and for this purpose a research station or experimental husbandry farm is proposed The need is also expressed for longer-term quantitative rainfall forecasts to avoid wasteful application of water

A few years ago any suggestion of irrigation in Great Britain would have produced a derisory reaction in most individuals This new Report, however, demonstrates quite clearly that the scientific application of water over much of lowland Britain would constitute a minor agricultural revolution, increasing output and strengthening our economic position immeasurably To bring this about, however, requires a national approach to the problem of water conservation in Great Britain Encouraging progress is, however, now being made in this direction[2,3]

DIAMOND PHYSICS

THE 1962 Diamond Conference, sponsored by the De Beers Group, was held at Cambridge during June 25–26, the delegates were accommodated in Gonville and Caius College, and the conference sessions took place in the Hopkinson Memorial Theatre The sixty or so members were drawn from universities, research establishments, and the research laboratories of the diamond industry; in addition to England and South Africa, the United States and several European countries were represented The attendance might have been greater had the First International Congress on Diamonds in Industry, with its scientific and technological sessions, not taken place in Paris only four weeks previously

The Diamond Research Laboratory in Johannesburg was the originator of this conference, and much of the work in this field is done by members of that body, either in their own departments or during secondment to other laboratories While the conference is not in itself a novelty (it has been held on twelve occasions previously), it has always been regarded up to now as a wholly private occasion, and for this reason no reports have been issued This has in no way implied a prohibition on publication (most of the papers presented have been published in some form in this or other scientific or technical periodicals), but formal Proceedings have not been issued, and direct reporting by the Press has not been allowed Although this meeting is still private in the sense that attendance is only by invitation, the papers are to be published as from the conference and reports of its activities will be permitted

As at all the previous Diamond Conferences, the range of the subjects covered was extensive, from the history of the early attempts at diamond synthesis to the latest investigations of present-day synthetics, and from geology to nuclear physics In fact, although the history of research into the nature and properties of diamond has a respectable antiquity, there is still a vast field for further exploration into a material that is unusual from a number of points of view

The conference was divided into four sessions, the morning of June 25 was devoted to the nuclear physics and electronics aspects of diamond, while the afternoon covered the geological aspect and the growth history of diamonds Tuesday morning had as its principal subject the mechanical strength of diamond, and the afternoon was given up to a miscellany of papers The conference ended with a dinner in the hall of the College, not the least important part of conferences such as these is the opportunity they give for meeting and talking informally to other workers in the same field

As has now come to be expected on these occasions Prof S Tolansky (Royal Holloway College) produced a number of remarkable slides of the surfaces of diamonds, both natural and synthetic, produced by the multiple beam interference method which he has developed to a high degree of excellence Another paper illustrated by extremely interesting pictures was that prepared by Dr T. Evans and C. Phaal (University of Reading) and presented by Dr Evans The subject was "Transmission Electron Microscopy in Diamond", and the description of the techniques used for the preparation of the samples was as interesting as the results obtained

The three papers presented by Dr D R Grantham (Selection Trust), Dr. P Stevenson (Royal Holloway College) and Dr M. Seal (Engelhard Industries Inc) on coated diamonds and growth history of diamond crystals produced some controversial matter, it is clear that this is a field in which a considerable amount of investigation still remains to be carried out Even the meaning of the commonest of all the surface features of natural diamonds—the trigons that appear so numerously on the octahedral faces—still remains in doubt, and the two schools of thought that relate them respectively to growth and to etching seem to be still far from reaching agreement, it is interesting to note that these features seem to be rare on synthetic diamonds, although very common on the natural stones

Dr E M Wilks (University of Oxford) produced some interesting facts on the effects of neutron irradiation on the mechanical strength of diamond, including a checkered cracking effect produced during polishing the diamond (by methods similar to those used in gem polishing), these, to judge by the illustrations shown, may well be analogous to the 'fire marks' known to be produced in polishing synthetic sapphire, which are due to local strain

The cleavage of diamond and the propagation of fractures were dealt with by Dr J H Brunton (University of Cambridge) and Dr J E Field (University of Cambridge) respectively Dr Field's ultra-high-speed photography and the calculations resulting from it have produced interesting information about the speed and method of the propagation of cracks started by small explosive charges and mechanical impact at different points in sample pieces, and Dr. Brunton's paper made it clear that the differences of energy involved are not in themselves sufficient to account for the marked preferential cleavage of diamond along octahedral planes

In a second paper, read during the last session of the conference, Dr Seal reported on electron microscope investigations made on the 'Hannay Diamonds' from the British Museum (Natural History), and although his results were not conclusive he appears to have added some further evidence for the genuineness of Hannay's success in diamond synthesis, Dr. H J Milledge announced that University College, London, was undertaking further work on these diamonds using X-ray diffraction methods, and the results of these investigations will be awaited with interest

As is natural with a conference of this type occurring annually, much of it was taken up by what can only be called interim reports, giving the outline of the advances made during the past twelve months, rather than final and conclusive statements on completed programmes, this does not detract from its interest, but rather adds interest to the prospects for the future occasions J F P H Greene

INDUSTRIAL CHEMISTRY IN BRITAIN

The ninety-eighth annual report on Alkali, etc , Works by the Chief Inspector for England and Wales covering the year 1961* records 10,583 visits and inspections during the year, including 264 special visits by the Chief and Deputy-chief Inspectors, compared with 9,861 in 1960 Of these, 429 were to, or in connexion with, works not registered under the Act, 21 were concerned with control of radioactive emissions and 102 were to, or in connexion with, colliery spoilbanks During the inspections, 6,992 quantitative analyses were made of gases evolved from the processes in operation, compared with 3,724 in 1960 Most of the increase is due to a special investigation concerning salt glazing of earthenware, where 3,065 tests were made, compared with 1,060 in 1960 In addition, 541 special samples, compared with 486 in 1960, were taken and submitted for analysis to the Government Chemist

As a result of the special investigation just mentioned, it was concluded that for the present the practice of salt-glazing must be accepted There is no available suitable alternative to common salt and scrubbing the gases would involve a heavy financial burden on the industry Pending a solution of the acid or mist removal problem, or the adoption of other glazing techniques, the provisional 'best practical means' is a chimney not less than 120 ft high for salt addition up to 1 5 cwt , research work by the British Ceramic Research Association should continue In connexion with sulphuric acid works, the report directs attention to a tendency for over-reliance on recording instruments, which especially on acid works need routine check by conventional analytical methods, particularly following a shut-down, temporary by-passing, etc , when for one reason or another the instrument does not always respond The report includes interesting reviews of developments in the fertilizer industry during the past 80 years and of the many developments in chlorine works since chlorine came into commercial use, also the experience of the Inspectorate of the past three-and-a-half years in the iron and steel industry is also briefly reviewed

The Chief Inspector for Scotland reports that progress in dealing with industrial air pollution to bring it within the requirements of the Clean Air Act has out-paced reduction of pollution from its main evil—the domestic fire Besides 552 visits of inspection under the Act, 178 miscellaneous visits were paid and 79 visits on work not directly related to the Act A study was made of existing industrial chimneys and the heights of 150 chimneys were plotted against the fuel-burning rates of the furnaces When industrial chimneys were built to create draught, even quite small installations were provided with chimneys higher than present-day standards In consequence, smoke was taken well clear of any downward movement of air due to wind turbulence created by surrounding property—a point liable to be overlooked to-day

ARID ZONE RESEARCH

In the budgetary year 1956–57 the United Nations Educational, Scientific and Cultural Organization decided to convert its research programme on the problems of arid lands into a "Major Project" for a period of five years This meant that larger allocations of funds and personnel were channelled into this field of work Though some polar areas may in fact be deficient in moisture, the arid regions which were calculated to cover 23 per cent of the Earth's land surface lie mainly in two broad but interrupted belts in northern and southern tropical and subtropical latitudes in lands which are, with the major exception of South Africa, members of Unesco One major result of the research programme has been the publication of a series of quarto volumes under the general title *Arid Zone Research*, of which the one under review* is Vol 18

By virtue of its status as a unique international organization Unesco has been able to call on the best brains throughout the world in the preparation of these research volumes As authoritative statements of the present state of knowledge and research in such fields as climatology, hydrology, ecology, salinity, land use and many others, they stand unrivalled Whereas the whole series should automatically be on the shelves of every serious library, certainly in every university departmental library covering the many fields concerned, the truth is that their circulation and use remain lamentably small and restricted To take but one example in the research series, *The History of Land Use in Arid Regions*, with its world coverage, has a wealth of material not previously available in the languages of Western Europe and certainly not gathered together in one volume, yet indispensable if any planning for the future is to have a firm scientific basis

As a major project the arid zone programme comes to an end this year and this lengthy report of the main symposium, if it should prove to be the last volume in the series, would form a fitting climax The symposium was attended officially by 250 scientists from 33 countries, but the list of participants does not include the names of a number of world figures who certainly were present at the meetings.

---

* The Problems of the Arid Zone Proceedings of the Paris Symposium (*Arid Zone Research*, Vol 18) Pp xii+481 (Paris Unesco, London H M Stationery Office, 1962) 47 25 NF , 69*s* , 15 30 dollars

Apart from the inaugural and presidential addresses, 27 papers are printed, most were presented by their authors and followed by a discussion which is given in summary form The papers are arranged in four groups the state of scientific knowledge, nomadism, alternative uses of scarce water supplies and, finally, four papers on public awareness of the educational problem The thirteen papers in the general section deal with water, ground-water, climatology, microclimatology, soils, salinification, plant physiology and ecology, human ecology, insects, winds and solar energy and saline water conversion It is interesting to find nomadism objectively studied by the Food and Agriculture Organization and viewed as a proper use of semi-arid lands under adequate control—thus extending on a world-wide basis the famous Cain and Abel experiment of Israel

It would be invidious to select papers from this rich collection for individual comment , but three conclusions would seem to emerge The first is that the research needed is usually in the borderland between present-day accepted fields of knowledge, in fact, the interrelation of the many factors The second is the delicate balance, easily upset, which exists in arid lands between the biota, including man, and the environment The third is the need for an open mind, willing constantly to re-think and reassess the problems and their solution

L Dudley Stamp

DAIRY RESEARCH IN SCOTLAND

THE Hannah Dairy Research Institute at Ayr now has a staff of about ninety, of whom some thirty are qualified in agriculture or science The recent triennial report* shows that the entire process of dairying is being covered, from the production of food on the farm to the chemistry, biochemistry and bacteriology of milk and milk products The programme of research is agreed in consultation with the Agricultural Research Council (London) and the Department of Agriculture for Scotland

The previous report described a unique range of new equipment for respiration experiments with sheep and cattle, and a splendid new climatic laboratory It is evident that these have been put to immediate use and that the work in these fields is wisely receiving emphasis Thus the careful reader will find on p 33 further support for the conclusion that while rations differing considerably in composition may be equally valuable for satisfying the maintenance requirements of ruminants, their nutritive value for production may differ widely Much vital supporting information is now being assembled, on such questions as the effect of environment, movement and lactation on the energy requirements of sheep and cattle The eventual effect of this work may well be felt wherever feeding standards are used

Capital for the climatic laboratory was provided by the Colonial Office in order to obtain basic knowledge of value in the improvement of cattle in hot countries A broad and vigorous approach is being made to the study of factors that influence temperature regulation, heat tolerance and acclimatization Much of this may be of value also in temperate countries

This Institute is clearly making a major contribution to research on many aspects of Britain's greatest and most vital agricultural enterprise. It may be symptomatic of the times, but it will nevertheless be surprising in some other countries that less than 1 per cent of the money required annually should now come from voluntary contributions

Sufficient background is provided to enable the general reader to appreciate the reason for doing each piece of work While a great deal of factual information is included, ample references are given to enable the specialist to trace detailed reports As always, this report is impeccably edited

UPTAKE OF GLUCOSE, AMINO-ACIDS AND VITAMINS BY HUMAN AMNION CELL CULTURES INFECTED WITH A TICK-BORNE ENCEPHALITIS VIRUS

By Dr P HALONEN, L HJERP, M. PYHTILA and P. WECKSTROM

Department of Virology, University of Helsinki, and Microbiological Laboratory, Laaketehdas Orion Oy, Helsinki

CHEMICALLY defined media designed primarily for cell cultures are extensively used for the propagation of viruses in such cultures To obtain the maximal yield of viruses requiring a lengthy incubation and maturation time in cell cultures, change of the medium must usually be omitted Accordingly, the best medium for such virus propagation may not necessarily be of the same composition as that for optimal cell growth, when frequent change of the medium is possible To examine the basic aspects of this problem it appeared important to know whether a critical loss of metabolites from a chemically defined medium could be obtained during prolonged incubation of uninfected and virus-infected cell cultures This communication describes the changes in the concentrations of glucose, amino-acids and vitamins of the B-group in Eagle's minimum essential medium[1] in uninfected human amnion cell cultures and in cultures infected with a tick-borne encephalitis virus

Strain *A* 52 of the tick-borne encephalitis virus was selected because in the continuous line of human

v, virus-infected, *c*, control

amnion cells used[2] it multiplies well for 10–14 days without any apparent cytopathogenic effect. The cells were grown in Roux bottles in 0·5 per cent lactalbumin hydrolysate medium with 20 per cent calf serum. At the time of virus inoculation the bottles were washed three times with Hanks's solution and incubated for 2 hr. at 37° C in Hanks's solution in order to starve the cells in a medium devoid of amino-acids and vitamins. The cells, approximately 25 million per bottle, were infected with 1:100 diluted virus grown in mouse brain, that is, approximately 7 × 10^6 mouse infectious doses per bottle. After incubation for 1 hr. at 37° C the unadsorbed virus was washed twice with Hanks's solution. 60 ml. of the final medium containing Eagle's minimum essential medium and 0·1 per cent bovine albumin ('Bovine Plasma Albumin, Fraction V', Armour Pharmaceutical Co., Ltd., Eastbourne, England) was added to each bottle. The *p*H of the medium was kept at 7·0–7·2 with sodium bicarbonate. Periodically, samples were taken from the medium of 3–5 virus-infected bottles, pooled and centrifuged at 2,000 r.p.m. for 15 min. The supernatants were stored at −25° C and −70° C. Before chemical and microbiological assays the virus was inactivated for 1 hr. at 56° C. Identical samples were taken from the medium of the control bottles.

On each pooled sample virus titration was carried out in mice. Glucose, amino-acids and vitamins were determined as described elsewhere[3].

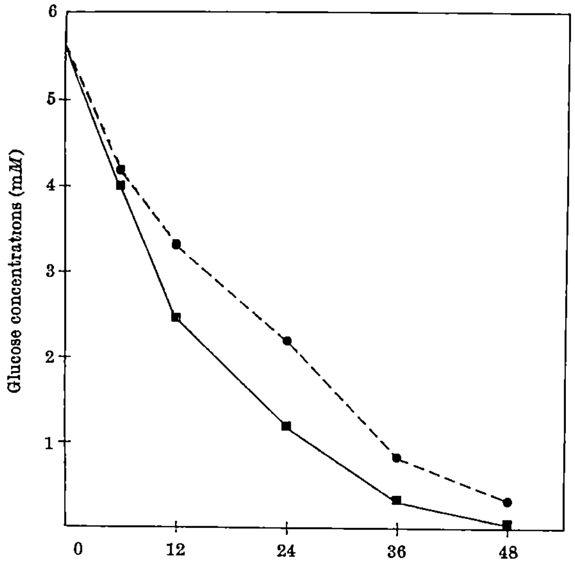

Fig. 1. Glucose concentrations (mM) in Eagle's minimum essential medium in tick-borne encephalitis virus-infected human amnion cell cultures and controls. ■, virus; ●, control

In a series of experiments the infectivity titre of the virus was about 5·0 log units/ml. at 24 hr. and 6·0 log units at 48 hr. After three days the titres decreased gradually but slowly. The titrations indicated that the maximal multiplication of this thermolabile virus occurred within 48 hr., but a considerable release of new infectious virus particles continued for at least 10 days.

Glucose concentrations were slightly lower in the virus-infected than in the control samples (Fig. 1). In 36–48 hr. they were less than 0·5 mM in both samples.

No significant change was observed in the concentrations of folic acid, inositol, pantothenate, riboflavin and thiamin in the medium of either the virus-infected cell cultures or the controls. In both samples, however, the concentration of nicotinamide decreased. After 8 days it was 20 per cent of the original biological activity in both samples and in 12 days below the detectable level in the samples taken from virus-infected cell cultures. The pyridoxal concentrations likewise fell, their values after 5 days being about 50 per cent of the original biological activity, but thereafter no further decrease was observed.

The amino-acid concentrations in a representative experiment are shown in Table 1. Three amino-acids (arginine, cystine and tryptophan) disappeared completely during some stage of the observation period of 70 hr. from the samples of both virus-infected and control cell cultures. Cystine disappeared from the control samples in less than 6 hr. In both samples glutamine concentrations were higher during the first day than in the original medium, but decreased rapidly during the next two days. The concentrations of isoleucine, leucine, methionine and valine also decreased significantly, the concentrations of histidine, phenylalanine, threonine and tyrosine to a lesser extent. In this connexion it is interesting to note that of the 5 amino-acids which are essential for human cell cultures in addition to the eight essential in feeding experiments in man[1,4], arginine and cystine disappeared from the medium in 12–34 hr. and glutamine almost completely in 70 hr., but in histidine and tyrosine a decrease of only about 50 per cent was observed in 70 hr.

It appears that, as regards the uptake of the metabolites in a chemically defined cell culture medium, only minor differences exist between human amnion cell cultures infected with a tick-borne encephalitis virus and uninfected controls. On the other hand, the disappearance of glucose and some amino-acids from the medium at an early stage may have influenced the multiplication of the virus after two days' incubation. Similar experiments are in progress with other viruses, and an investigation is being made of the effect on virus yields of the addition of various metabolites[5].

A preliminary report of some of the results presented in this article was given at the thirteenth Scandinavian Congress for Pathology and Microbiology in Turku[6].

We thank Mrs. T. Nummela for technical assistance.

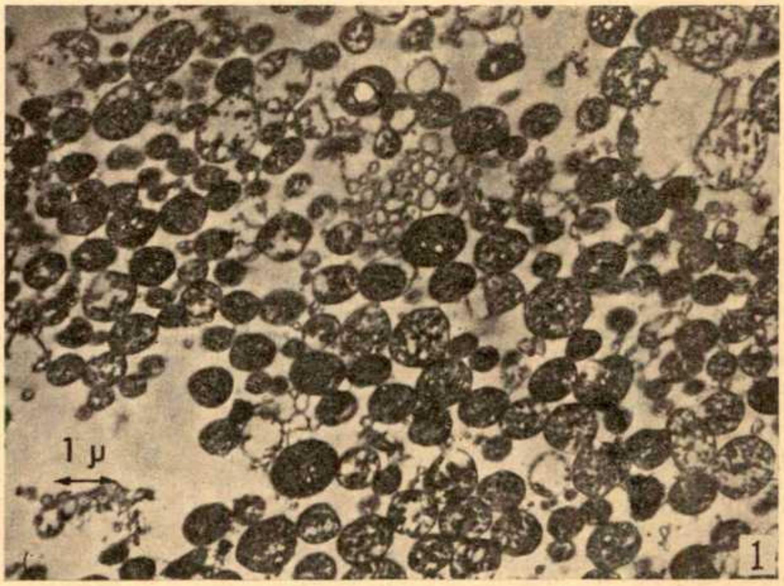
STRUCTURE AND ENZYME ACTIVITY

By P. F. BAKER, DR. D. H. NORTHCOTE and SIR RUDOLPH PETERS, F.R.S.

Department of Biochemistry, University of Cambridge

AT the present moment there is an awakening of interest in the relation of structure to the function of various organelles of the cell, as the background to a more complete understanding of the behaviour of the living cell[5]. In this connexion, it seemed interesting to examine the action of long-chain fatty acids on mitochondrial structure. The effect of long-chain fatty acids (C_{10}–C_{14}) on the oxidation of pyruvate (pyruvate oxidase system) in brain brei (pigeon) has been known for many years, since it was found that a concentration of about 1·0 mM at 37° stopped the action of the pyruvate oxidase system[6]. For 1·6 mM of C_{12} acid the decrease in respiration was 79 per cent and for C_{10} 59 per cent. It appeared that the acids were displacing some essential component of the pyruvate oxidase system by a surface action. This action seemed to be analogous to an effect of these acids at a similar concentration on the green chromoprotein, ovoverdin, from the egg of the lobster; addition of the acid changes the colour from green to red, which is the colour of the component astaxanthin. It was known in 1938 that the pyruvate oxidase system was a complex of enzymes, and it is to be noted that the succinate system in brain tissue was found to be more stable[6].

Since these experiments were reported, it has been found that pyruvate oxidation in brain tissue of the pigeon does involve the enzymes of the citric acid cycle[1,7], which enzymes are organized inside the mitochondria[3,8]. In view of this more recent information, we have investigated the effect of dodecanoic acid (lauric, C_{12}) on the respiration and the structure of mitochondria prepared from the kidneys of guinea pigs. It was con-



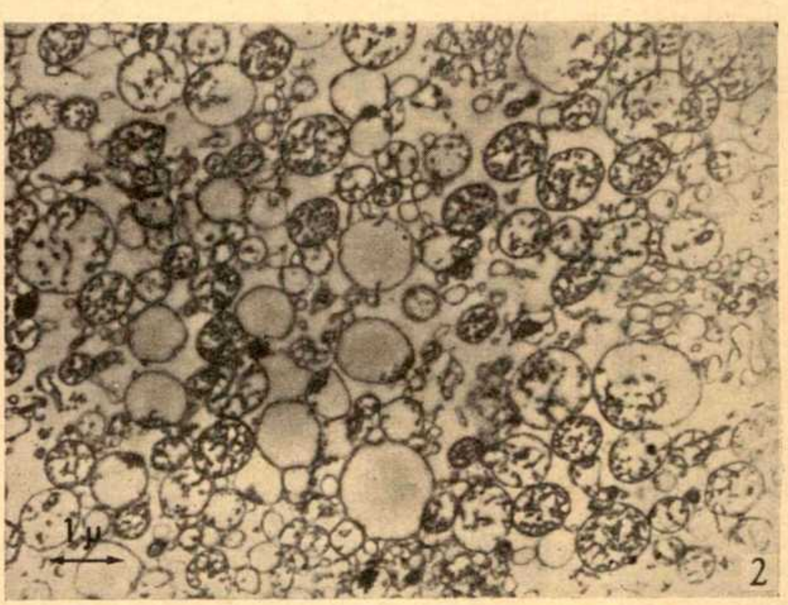


Fig. 1. Section of a normal preparation of mitochondria from kidney of guinea pig. The material was fixed in osmium tetroxide

Fig. 2. The same preparation as shown in Fig. 1 after treatment with sodium laurate for 2 min at 37° C

Table 1. EFFECT OF DODECANOIC ACID (C_{12}) ON THE METABOLISM OF KIDNEY MITOCHONDRIA

The reactions of the citric acid cycle were blocked with fluorocitrate at the aconitase stage, so that the citrate formed is a measure of the activity of the reactions from pyruvate to citrate.

Experimental. The kidneys from one guinea pig were homogenized in a hand homogenizer in 1 per cent potassium chloride solution at 0° C. After removal of nuclei, etc., by slow centrifugation for 15 min the supernatant was centrifuged at 7,000 r.p.m. (approx.) for 20 min. The pellet of mitochondria was resuspended in 11 ml. of 1 per cent potassium chloride solution and 11 ml. imidazole buffer (0·05 M) at *p*H 7·0. Each 50-ml. Erlenmeyer flask contained 2·0 ml. of the mitochondrial suspension, magnesium 4·0 μmoles (0·1 ml.), adenosine triphosphate 1·2 μmoles (0·2 ml.), sodium fumarate 20 μmoles (0·2 ml.), sodium pyruvate 10 μmoles (0·1 ml.), fluorocitrate (syn) 20 μg 0·05 ml., sodium dodecanoate neutralized to *p*H 7·0, 1·0 mg (or 0·5 mg) in 0·1 ml. and 1 per cent potassium chloride to a total volume of 3 ml. The duplicate flasks were gassed with 95 per cent oxygen, 5 per cent carbon dioxide and incubated for 30 min at 37° C, after which 1·0 ml. 25 per cent trichloroacetic acid was added. The duplicates were pooled, filtered and made up to 20 ml. for estimation of the citric acid present.

Citrate formed in 30 min at 37° C per flask in μmoles.

Control	1·85
C_{12} acid 0·5 mg	0·664
C_{12} acid 1·0 mg	0·078

firmed that, as in brain tissue, laurate (1·6 mM) stopped the respiration of pyruvate (Table 1).

Two experiments were made for examination of the structure of the mitochondria by the electron microscope, and in each case the mitochondria from a single preparation were divided into two samples, one of which was treated with laurate and the other sample used as a control.

In the first experiment the mitochondria were exposed to laurate (1·0 mM) (neutralized to *p*H 7·0) at 37° for 10 min. After this the suspension was cooled to 0° C and centrifuged to form a pellet. This pellet was fixed with 1·0 per cent osmium tetroxide dissolved in the medium used for the mitochondrial preparation for 30 min at 18° C. After dehydration the fixed mitochondria were embedded in a mixture of butyl methacrylate, 85 per cent; methyl acrylate, 15 per cent; and thin sections cut with a glass knife and examined with the electron microscope. In this first experiment a complete breakdown of the mitochondrial structure was shown. A second experiment was therefore performed in which the exposure to the fatty acid was less drastic; the mitochondria were divided into three batches which were exposed for 2 and 5 min respectively at room temperature, and at 37° C for 2 min. After this they were embedded and cut as before.

As would be expected, the untreated mitochondria prepared in 1·0 per cent potassium chloride were rounded, though they showed good biochemical behaviour so far as pyruvate oxidation was concerned. The mitochondria exposed to laurate at room temperature showed some changes; several of the mitochondria had lost their internal structure. But in those exposed to lauric acid at 37° C practically no cristæ were visible (Figs. 1 and 2). Only the limiting membranes of the mitochondria remained and even these were sometimes ballooned.

It is clear that the loss of the biochemical activity in mitochondria exposed to long-chain fatty acids is correlated with a virtual disruption of the internal structure; this may result from the penetration of an excess of undissociated fatty acid molecules. This can be inferred from the fact that in an interface between a lipoid and aqueous phase[4] long-chain fatty acids are less dissociated than they are in a bulk solution of the same *p*H. Our observations are clearly related to those of Emmelot[2]. He considers that adsorption of long-chain fatty acids may explain some details of the behaviour of mitochondria isolated from strains of hepatoma; for example, the decreased dinitrophenyl-activated adenosine triphosphatase of the hepatoma particles as compared with those of liver mitochondria, and also the pattern of swelling, which is different in the tumour preparations. It was pointed out in the earlier paper[6] in 1938 that traces of fatty acids would influence experimental results in isolated enzyme systems.

In conclusion, it has been found that treatment of mitochondria at 37° C for 2 min with the C_{12} fatty acid (dodecanoate) removed the internal structure at the same time that it eliminated the oxidation of pyruvate by the enzymes of the citric acid cycle. The fact stresses the importance of structure in some organized actions of enzyme systems.

We thank Mrs. P. Legge for technical assistance, and also the Shell Co. and the Wellcome Trustees for grants, and Prof. F. G. Young for facilities privided.

EFFECT OF MAGNETIC FIELDS ON TUMOUR IMMUNE RESPONSES IN MICE

By DR. LEO GROSS

Waldemar Medical Research Foundation, Port Washington, New York

THE biological effects of magnetic fields have been investigated in several recent studies. Barnothy *et al.*[1] have shown that a leucocytosis is produced after exposure to static magnetic fields, and Audus[2] has shown a magnetotropism in plants. We[3] have tested for an effect of magnetic fields on tumour growth in mice. Gross and Smith[4] have reported a delay in wound healing produced by magnetic fields.

We have sought a means of assaying the biological effects of magnetic fields. An experimental situation wherein 50 per cent of the experimental animals succumbed to the treatment as commonly used in pharmacological dose-level tests was felt to be a sensitive point at which to test. My colleagues and I have reported a means of protecting mice against transplantable tumours by a series of immunizing injections[5] of X-ray-attenuated tumour cells. The extent of protection was determined by challenging with a measured number of viable tumour cells, and an LD_{50}-level was established.

These mice received weekly intraperitoneal injections of 5 million Ehrlich's ascites carcinoma cells that had been previously attenuated by X-irradiation with 4,000 r A series of six such injections resulted in 50 per cent of the mice (LD_{50}) being able to withstand a challenge of 10 million live untreated cells injected intraperitoneally one week after the course of immunization Animals so protected and challenged were then placed in magnetic fields, and a marked effect was detected

Twenty-four such protected and recently challenged *C3H* mice were placed within a relatively uniform magnetic field of 4,000 gauss produced by 'Alnico' magnets with 2-in diam pole faces and a 2-in gap The variation across the field of the 24 magnets did not exceed 200 gauss for the volume within which the mice were confined

Animals under test were housed for the duration of the experiment in individual cubical containers constructed of non-magnetic stainless steel wire mesh approximately 2 in on a side Some of the controls and the mice exposed to magnetic fields were so housed, additional control animals were housed in the usual manner in our mouse colony with six animals per pen All animals received food and water *ad libitum* These groups were equalized with respect to age, weight, and sex

The mice were observed after the challenge dose, for tumour growth and survival

Highly inbred mice of *C3H* strain were used in this experiment (Table 1)

Table 1

	Magnetically treated	Untreated Individually housed	Untreated Normally housed
No of animals	24	24	24
No surviving challenge	3	12	13
Average life-span for animals succumbing to challenge (days)	15 9	16	16
Mortality-level (*LD*) (%)	87 5	50	45 8

For a second test, some *C3H* animals which had been treated with purified protein derivative of mycobacteria and with X-ray attenuated Ehrlich's ascites were used The effect of the purified protein derivative thus used as an adjuvant was to raise the protection-level as determined by challenge and survival to an LD_{50} at approximately a 30 million cell dose This higher dose was injected into the animals in this second test (Table 2)

Table 2

	Magnetically treated	Untreated individually housed
No of animals	23	17
No surviving challenge	2	4
Average life span for animals succumbing to challenge (days)	15	17
Mortality-level (*LD*) (%)	91 3	76 5

Analysis of the results shows an LD_{50}-level in the control animals, and a higher mortality in the magnetically treated animals, equivalent to an $LD_{87\ 5}$ In the second trial, the immunization-level of the mice was higher but the dose was not accurately estimated to produce an LD_{50} in the controls Nevertheless the same relationship of fatalities in magnetically treated mice to controls was obtained, namely, 91 3 to 76 5 per cent The *P* values of these tests are significant with a probability level of $P < 1$ per cent

Tests conducted with mice that did not receive a prior course of immunizing injections before challenge showed no perceptible difference between magnetically treated mice and their controls

This effect of the magnetic field is marked Mice kept within the magnetic field succumb in larger numbers to an LD_{50} challenge dose of a transplantable tumour than do similarly treated controls

It is fair to assume that the protective mechanisms of the mice arrayed against Ehrlich's ascites tumour is in some way impaired by the action of the magnetic field At the critical LD_{50}-level or close to this level, this impairment in magnetic fields is revealed with more sensitivity We have postulated, in view of the delay in wound healing in magnetic fields[4] and in light of developmental anomalies on fruit flies observed by Mulay *et al* [6] in magnetic fields, that the production of antibody titres would be reduced in the presence of magnetic fields We are measuring such antibody titres in mice, and results to be published later show a diminution of antibody titre-levels in mice resident in magnetic fields

We thank the Raytheon Manufacturing Co for providing the magnets used in these experiments This work was supported in part by U S Public Health Service, National Institutes of Health, grant No. *C*4561*C*2

GLUCOSE METABOLISM IN RAT BRAIN *IN VIVO*

By Dr R VRBA

Medical Research Council, Neuropsychiatric Research Unit, Carshalton, Surrey

THE brain is unusual among the larger organs in its dependence on glucose[1,3] It is generally believed that processes of glycolysis, of the tricarboxylic acid cycle and of the direct oxidative pathway through pentose phosphate are the main metabolic pathways of glucose in the brain[1-3]

During the past ten years evidence has accumulated that glucose can be converted into amino-acids in the brain Labelled α-amino-acids were isolated from brains of neonatal and young mice[4] after injection of glucose-U-^{14}C and from the brains of adult rats after injection of glucose-1-^{14}C and glucose-6-^{14}C (ref 7). Similarly, rapid formation of labelled amino-acids was found *in vitro* after incubation of brain cortex slices with glucose labelled with carbon-14 (ref 5) and after introduction of glucose-U-^{14}C into 'artificial blood' used for perfusion of the brain of a cat with isolated circulation[6]

In this article the main results are presented of experiments in which some pathways of glucose metabolism in brain were followed from 1 min up to 5 hr after introduction of glucose-U-^{14}C into intact circulation These experiments form part of a more extensive investigation which has been published in full elsewhere[9]

Glucose-U-^{14}C was injected into the tail vein of rats which were decapitated at intervals, of 1, 2, 5, 10 and 30 min after injection 0 5 ml of blood was collected immediately and deproteinized with acid The brain was quickly dissected and placed in ice-cold 0 25 *M* sucrose, homogenized at 0° C in a mechanical homogenizer[8], deproteinized by addition of concentrated perchloric acid to a final concentration of 5 per cent of the acid (w/v) and fractionated into various chemical fractions, as outlined in Table 1 It may be seen from Table 1 that already 2 min after injection of radioactive glucose, 41 per cent of the total radioactivity found in the brain was there in the form of α-amino-acids, and this figure increased to 75 per cent after 30 min

Table 1 DISTRIBUTION OF RADIOACTIVITY IN RAT BRAIN AFTER INTRAVENOUS INJECTION OF GLUCOSE-U-^{14}C

Fraction	Sub-fraction	Time between injection of glucose-U-^{14}C and decapitation of the rat (min) 0†	1	2	5	10	30
Acid-soluble	*a* Non-amino-acid fraction	95 84	66 67	58 01	42 63	41 76	22 35
	b Amino-acids	3 51	26 51	40 97	55 99	55 36	74 78
Lipid	*a* Acetone extract	*	*	0 54	0 85	1 96	1 60
	b Ethanol-ethyl ether extract	*	*	*	*	*	*
	c Chloroform methanol extract	*	*	*	*	*	*
	d Acid chloroform methanol extract	*	*	*	*	*	*
Nucleic acid	*a* Hot HClO$_4$ extract	*	*	*	*	*	0 29
	b Lipid impurities	*	*	*	*	*	*
Protein	*a* Carbohydrate impurities	*	*	*	*	*	0 15
	b Amino-acids	*	*	*	0 17	0 33	0 65
	c Humines	*	*	*	*	*	*
	Total	100	100	100	100	100	100

Results are expressed as percentages of total radioactivity in 1 gm fresh weight of brain Only counts exceeding the double of the background are considered of significance Values replaced with asterisks can be considered as practically negligible because they are below limits of the reliable resolution power of the method The results were corrected for background and self-absorption Each active sample was plated in duplicate and at least 6,000 counts were taken in a Nuclear Chicago automatic Geiger counter For further details of methods see ref 9

Female litter mates (120 gm each) were injected into the tail vein with 0 2 ml of glucose-U-^{14}C (15 μc) in presence of 2 38 mgm. carrier glucose The glucose was provided by the Radiochemical Centre, Amersham, England

† Control = animal was not injected but glucose-U-^{14}C added to the solution in which the dissected brain was homogenized All other procedures were identical with those to which the brains of animals injected *in vivo* were subjected This serves as a check for the separation methods

Among the acid-insoluble substances, the acetone-soluble lipids were those most labelled It was possible to demonstrate their radioactivity within 2 min of injecting glucose-U-^{14}C into the circulation It is unlikely that the counted radioactivity is due to adsorption, because it is evident that the number of counts and percentage of total brain activity in this fraction were not dependent on the absolute amount of radioactivity in brain, but on the time which had elapsed from the moment of injection of glucose-U-^{14}C into circulation The labelling of brain proteins was relatively small during the first 30 min , although 5 min after injection of glucose-U-^{14}C it was possible to demonstrate the presence of carbon-14 in brain proteins

Results expressed as percentages of total acid-soluble radioactivity obtained from 1 ml blood or 1 gm fresh weight of brain Figures in parenthesis indicate counts/min /ml. blood or 1 gm brain respectively For all other conditions see Table 1

Only 30 min after intravenous injection of glucose-U-^{14}C was it possible to show unequivocally the presence of carbon-14 in the 'nucleic acid' fraction The relatively high rate of conversion into amino-acids points to the importance of this process in the function of the brain This is corroborated by the fact that conversion of glucose into amino-acids proceeds in brain at a rate of several times that in liver, kidney, heart, lungs, spleen, skeletal muscle or blood[9] The results shown in Table 2 show unequivocally that the radioactive α-amino-acids were formed from glucose in brain and not transported to the brain by circulation. Even 30 min after injection of glucose-U-^{14}C the α-amino-acids in blood contain less than 1 per cent of the total acid-soluble radioactivity of blood The specific activity of α-amino-acids in the blood is only a small fraction of the specific activity of α-amino-acids in brain The amino-acids of brain were further separated on 'Dowex' anion exchange resin into monocarboxylic and dicarboxylic α-amino-acids using Gaitonde's method[10]. The dicarboxylic α-amino-acids were then separated into glutamic acid and aspartic acid by chromatography on alumina according to Darling's method[11] These separations provided information on the distribution of carbon-14 between various α-amino-acids Data in Table 3 show that the dicarboxylic α-amino-acids have (several times) higher specific radioactivity than the monocarboxylic α-amino-acids Both glutamic and aspartic acids are highly labelled It may be further

Table 3 RELATIVE SPECIFIC ACTIVITIES OF ACID-SOLUBLE α-AMINO-ACIDS IN BRAIN AFTER INTRAVENOUS INJECTION OF GLUCOSE-U-^{14}C

Time after injection of glucose-U-^{14}C (min)	0 (control)	1	2	5	10	30
Monocarboxylic* α-amino acids	*0 001* (15)	*0 217* (273)	*0 404* (6,868)	*0 538* (13,823)	*0 264* (3,227)	*0 410* (15,066)
Dicarboxylic* α-amino-acids	*0 113* (1,322)	*0 584* (736)	*2 153* (36,563)	*2 163* (55,436)	*2 147* (26,217)	*2 591* (95,156)

* α-amino-acids were isolated from the acid-soluble fraction of brain using 'Zeo-Karb-225 *H*' form cation exchange resin (cf Roberts *et al*[4]) Thereafter they were passed through a 'Dowex'-carbonate column according to Gaitonde[10] (anion exchange resin '*AG*'1–10, 200–400 mesh, Bio Rad Laboratories, Richmond, California) and separated into monocarboxylic and dicarboxylic Before this separation glutamine was hydrolysed to glutamic acid

S A Specific activity = counts/min /mgm α-amino nitrogen

$$\text{Relative specific activity} = \frac{\text{specific activity}}{\text{counts/min /gm fresh weight of brain}}$$

seen that the relative specific activity of α-amino-acids reached an almost constant level in brain in less than 5 min after injection of glucose-U-^{14}C and an equilibrium of specific activity of α-amino-acids with total radioactivity in brain is reached and maintained. On the other hand, the data of Table 4 clearly indicate that during the first 30 min there occurs a constant enrichment of brain with carbon-14 derived from glucose-U-^{14}C injected into the circulation As shown in Fig 1, this is not in contradiction with the state of relative equilibrium mentioned above About half an hour after the injection of glucose-U-^{14}C into the circulation, the process of progressive elimination of carbon-14 from brain prevails (Table 5, row *f*) On the other hand, the carbon-14 still present in the brain is progressively more and more converted into acid-insoluble substances, mainly lipids and proteins (Table 5) Thus the main features of glucose metabolism in the rat brain *in vivo* can be characterized as follows

(1) Part of the glucose–carbon, which enters the brain from the circulation, is retained there for at least half an hour A fraction of this remains in the brain even after 5 hr and probably much longer.

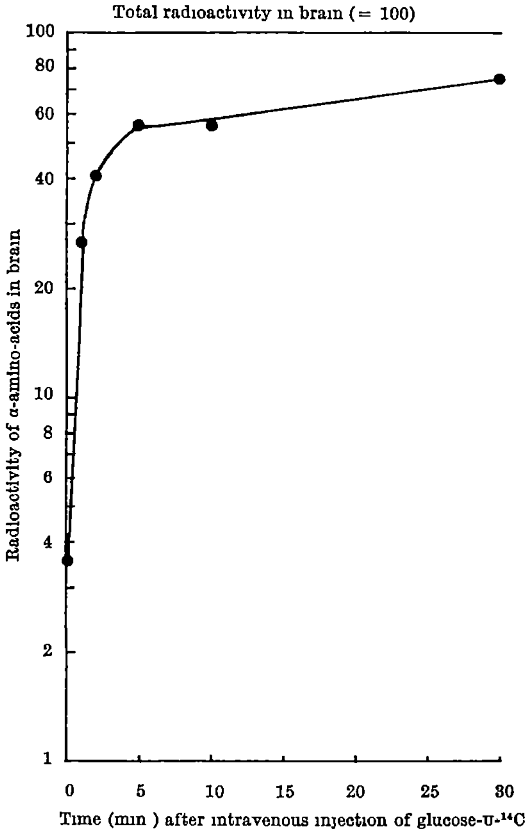

Fig 1

Table 5 DISTRIBUTION OF RADIOACTIVITY IN BRAIN DURING 5 HR AFTER SUBCUTANEOUS INJECTION OF GLUCOSE-U-^{14}C

Time after injection of glucose-U-^{14}C (hr)	0 5	1 0	2 0	4 0	5 0
a 'Acid-soluble' fraction	98 3	93 0	79 9	49 6	30 7
b 'Lipid' fraction	0 8	3 2	8 6	29 4	36 8
c 'Nucleic acid' fraction	0 5	1 0	2 3	5 6	8 2
d 'Protein' fraction	0 3	2 8	9 2	15 4	24 3
e Total (per cent)	100 0	100 0	100 0	100 0	100 0
f Total (counts/min / gm fresh brain)	6,126	3,001	2,152	840	1,070

Female litter-mates, 120 gm each, were injected subcutaneously over the left flank with 7 μc glucose-U-^{14}C in 0 2 ml water and 2 mgm carrier glucose Results expressed as percentage of total activity in brain

(2) At 2 min. after injection of glucose into the circulation, about 40 per cent of the glucose–carbon retained in the brain is in the form of α-amino-acids, mainly glutamic and aspartic acids In less than 5 min equilibrium of conversion of glucose into α-amino-acids is reached At this time more than 50 per cent of glucose-derived carbon present in the brain can be accounted for as α-amino-acid carbon.

(3) During the next 5 hr more than 80 per cent of the glucose-derived carbon is eliminated from the brain by a metabolic process involving oxidation of α-amino-acids, since the highly labelled α-amino-acids formed in the brain do not appear in any significant quantity in blood The glucose-derived carbon not eliminated from the brain during this period is converted into lipid, protein and other carbon substances.

It has been established by the classical work of Himwich and others[1], that the increase of carbon dioxide and lactic acid in brain venous blood can be accounted for quantitatively by the glucose consumed in the brain My experiments show that glucose–carbon introduced into the brain via the circulation is partially retained in the brain for a considerable period of time in the form of various substances The logical conclusion is that carbon dioxide eliminated from the brain is at least in part derived from oxidation of amino-acids, proteins, lipids and other 'non-glucose' substrates Only in this way could an equivalent amount of carbon dioxide be liberated by the brain in order to replace the glucose–carbon retained in the brain

It should be noted that there is independent evidence that a part of the carbon dioxide eliminated from the brain is derived from oxidation of non-glucose substances, particularly from α-amino-acids, lipids, proteins and nucleic acids[3,6,12,13]

I thank Dr Derek Richter for his support in this work

HYPOCHROMISM IN THE ULTRA-VIOLET ABSORPTION OF NUCLEIC ACIDS AND RELATED STRUCTURES

By DR. H. C. BOLTON
Department of Physics
AND
PROF. JOSEPH J. WEISS
Department of Chemistry
King's College, University of Durham, Newcastle upon Tyne

IT has been known for some time that there is a considerable increase in the ultra-violet absorption of nucleic acids (RNA and DNA) on degradation to the corresponding nucleotides, that is, the arrangement of nucleotides in nucleic acids and polynucleotides causes what has become known as a hypochromic effect.

Earlier statements that this effect is due to the interaction of the π-electrons of the bases do not provide an explanation. In a more recent paper, Tinoco[1] attempted to apply exciton theory to account for this hypochromism. However, as has already been shown by Rhodes[2], this treatment cannot account for the effect.

Rhodes[2] attempted to give a theory for the hypochromic effect on the basis of what he terms 'first order exciton theory'' taking into account dispersion forces, but there is no clear statement in his paper about quantitative results. Moreover, it appears that Rhodes's considerations are based on the assumption that hypochromism is solely due to the coil–helix transformation. His considerations leave unexplained the fact that hypochromism is not confined to the strand–helix transformation, as in fact it has been shown[3] that even dinucleotides can exhibit some hypochromic effect (~10 per cent), which in some simple polynucleotides was found to reach a limiting value up to 35 per cent at chain lengths of about 10 nucleotide units.

Previous work on the basis of the exciton theory has dealt mainly with the structure of the absorption spectra of solids, that is, the shift and broadening of the absorption bands[4]. However, in going from mononucleotides to nucleic acids, there is no marked change in the position and shape of the absorption band but a very pronounced decrease in the extinction coefficient at maximum absorption, that is, hypochromism. The explanation of this effect must therefore be sought on different lines.

It had been suggested by one of us[5] that the hypochromic effect is basically a 'medium effect' and is related to some interaction between the nucleotide units within the 'molecular crystal' of a polynucleotide.

In general, the behaviour of a molecule with a dominant absorption band under the influence of a light wave may be considered as a classical electron oscillator in the field of the light wave and the average field of the other oscillators. The classical theory of an isolated oscillator was given by Rosenfeld[6] and the equivalent quantum mechanical theory by Heitler[7].

The reduced light absorption arises from the fact that in a medium consisting of similar units (for example, in a crystal) there is a reduced dissipation of energy as the energy lost by an oscillating dipole is regenerated to a greater or lesser extent by the coherent action of the radiation coming from the other dipoles. It should also be clear that, in these situations, the simple spectroscopic sum rule does not apply as its derivation relates only to the strength of the absorbed (or scattered) radiation expressed in terms of the incident amplitude at the position of the absorbing molecule and does not allow for a modification of this incident amplitude by the presence of other scatterers or absorbers.

To obtain a quantitative estimate of the light absorption of a polymer crystal of N monomer units, one can start with a model where the polarizability tensors of each of the N units are arranged in some pattern in the macro-molecule. The light absorption in the polymer is related to the polarizability tensor of the monomer through the theory of the internal field in the N-mer.

We include absorption by treating the polarizability as a complex quantity; similarly the refractive index can be written as

$$n = n' - ik \qquad (1)$$

where k is the absorption coefficient. Decreased light absorption, that is, hypochromism, would then mean that the absorption coefficient per monomer unit of an N-mer is not a constant but decreases with increasing number of N up to a certain limit. This, at first sight, may seem surprising, but this is simply due to the fact that any selected unit has its near neighbours *correlated* according to the structure of the polymer and not randomly arranged. The problem is essentially similar to that first discussed by Ewald[8].

One can now see immediately how the absorption maximum of an N-mer will behave compared to that of N separate monomers. The corrections with the field acting on a particular molecule arising from local structure will be the fields of neighbouring dipole oscillators in the polymer. At the maximum absorption these absorbing dipoles will have a polarizability which has a large if not dominant imaginary component. There will thus be a quadrature component of the local field in addition to the usual field, and the resulting component, which is exciting the dipole moment, is reduced. It is the introduction of the local correlation which produces decreased light absorption (hypochromic effect).

It must be emphasized that we are assuming polarizable units and consequently localized dipoles. Since a polymer is itself a single molecule or even a one-dimensional crystal, excitation and absorption are in a sense a collective property of the polymer and not of the separate units.

Calculation for Dimers and N-*mers*. The method of calculation which has been adopted can be illustrated by the following particularly simple model, namely, the case of a dimer with isotropic units. The field acting on any particular absorbing unit will be the radiation field and the field of all the other molecules

The random arrangement of molecules implies that there are two transverse and one longitudinal positions and therefore, for example, the average polarizability of the monomer unit (within a dimer) is given by $\alpha\,\xi$, where

$$\xi\,(X) = \frac{1 - X}{1 - X - 2X^2} \tag{2}$$

and $X = (\alpha/d^3)$ is a dimensionless factor, α is the polarizability of the monomer and d the distance between the dipole oscillators

The equations needed to link polarizability and absorption coefficient have been given in Seitz[9] At the centre of the absorption band where $\nu = \nu_m$, the polarizability α of a single unit is given by

$$\alpha = f\,e^2/(4\,\pi^2\,m\,i\,\nu_m\,\nu_d) \tag{3}$$

where f is the oscillator strength, ν_d is a damping frequency, e and m are the charge and mass respectively of the electron We introduce the non-dimensional parameter

$$y = f\,e^2/(d^3\,4\,\pi^2\,m\,\nu_m\,\nu_d) \tag{4}$$

where d is the shortest distance between the absorbing units in the polymer.

The expression for the maximum absorption coefficient k_m is given by[9]

$$k_m = C_N(y)\,N_0\,y\,d^3\,(4\,\pi/3)\,(n' + 2)^2/6n' \tag{5}$$

where N_0 is the concentration of monomer units and n' the refractive index of the solution. The influence of the correlation on the light absorption of an N-polymer is expressed by the factor $C_N(y)$ which is the real part of the correction factor $C_N(y) = Re\,\xi\,(-iy)$

It is an easily observable fact that in going from a mononucleotide to a polynucleotide the position and width of the absorption bands, which are at about 2600 Å, do not change very much, therefore the maximum absorption coefficient of an N-mer in solution per monomer unit can be expressed to a good approximation by

$$k_m/N_0 \propto C_N(y) \tag{6}$$

Correlation factors for several N-mers are given here the subscript is the number of units in the molecule and the superscript indicates whether the transverse (T) or longitudinal (L) moments or both have been taken into account

For isotropic polarizabilities ($L + 2T$) one obtains for the dimer ($N = 2$) (from equation (2)),

$$C_2^{L+2T} = \frac{1 + 3\,y^2}{1 + 5\,y^2 + 4\,y^4} \tag{7}$$

There are only algebraic complexities to extend the argument to longer chain polymers For an infinitely long chain we need the summation $\sum\limits_{S=1}^{\infty} 1/s^3$ which is the Riemann zeta function of order 3, it was given by a Ferranti–Pegasus computer programme to a sufficient accuracy as 1.2021 along with other series needed in other calculations

Thus one obtains for an infinitely long chain ($N = \infty$)

$$C_\infty^{L+2T} = \frac{1 + 17.3\,y^2}{1 + 28.9\,y^2 + 133\,y^4} \tag{8}$$

For N-mers taking into account only transverse polarizability

$$C_2^T = 1/(1 + y^2) \tag{9}$$

$$C_\infty^T = 1/(1 + 5.78\,y^2) \tag{10}$$

Taking into account only the longitudinal polarizability

$$C_\infty^L = 1/(1 + 23.1\,y^2) \tag{11}$$

In the last three cases, the right-hand side of equation (5) should be multiplied by a factor of 1/3 because of the averaging

Double Helix in Nucleic Acids The model chosen is a helix of base pairs of linear oscillators arranged in planes, the two dipoles making an angle 10.4° to each other[2] The line of the oscillator is the line of long axis of the base Each base pair is rotated with regard to its neighbours by an angle 36° For simplicity, the only interactions considered are those between dipoles in the base pair and the four neighbouring dipoles in the two adjacent base pair planes. For the helical dimer one gets for $N = 6$, that is, the interaction of one base with its five nearest neighbours, the following equation

$$C_6^{\text{helix}} = \frac{1 + 14.3\,y^2 + 45.9\,y^4}{1 + 20.2\,y^2 + 102\,y^4} \tag{12}$$

and to a first approximation it may be assumed that $C_6^{\text{helix}} = C_\infty^{\text{helix}}$ The distance d is taken here to be both that between dipoles and between the planes of the base pairs

The foregoing results show that the transverse polarizability, that is, in the plane of the bases, makes a contribution towards hypochromism but the longitudinal polarizability (along the helix) has a relatively much stronger effect, as can be seen by a comparison of equations (10) and (12) with equation (11) In a single strand with a rigid structure the longitudinal polarizability could be very important This will, however, not be the case when the single strand assumes, to a greater or lesser extent, the configuration of a 'random coil', as then the hypochromism due to longitudinal polarizability may be negligibly small If, however, two strands are combined to form a double helix which behaves like a 'rigid rod', correlation due to the longitudinal polarizability will be restored and the full hypochromic effect due to it will manifest itself

From these considerations the magnitude of the observed hypochromic effect in nucleic acids, that is, an increase in the maximum absorption coefficient in the ratio of about 1.14 in going from the double helix to the single strands and a similar increase in going from a single strand to the mononucleotides, can be calculated on the basis of the Watson–Crick model[10] using equations (10) – (12), with values of the parameters $y^{(T)} = 3 \times 10^{-1}$ and $y^{(L)} = 2 \times 10^{-1}$ for the transverse and longitudinal polarizability respectively. These numerical values correspond to mean oscillator strengths of $f^{(T)} = 0.21$ and $f^{(L)} = 0.14$ as derived from equation (4) for an absorption frequency $\nu_m = 10^{15}$ sec^{-1} and a damping frequency $\nu_d = 10^{14}$ sec^{-1} and $d = 3.5$ Å

In this way, these calculations give some insight into the light absorption of nucleic acids connected with the 'random coil'–helix transformation It is not only the regular arrangement of the bases in the helical configuration but particularly the fact that the formation of the double helix leads to a more or less rigid, well-ordered, rod-like structure which is responsible for the hypochromism due to correlation effects in the nucleic acid molecular crystal

REGENERATION OF PROTHROMBIN ACTIVITY BY PLASMA ALBUMIN AND GLOBULIN FRACTIONS

By Dr. B C. DAS*
Case Institute of Technology, Cleveland 6, Ohio

THE agents responsible for blood coagulation must be able to circulate freely in the blood and yet be able to form a clot at the site of injury to the body. Two agents of primary importance in the process of blood coagulation circulate in the blood as the proteins prothrombin and fibrinogen Prothrombin is a precursor to thrombin, it is converted to thrombin when blood leaves the circulation and comes into contact with some foreign surface The thrombin can then convert the soluble protein fibrinogen into insoluble fibrin, which forms the network of fibres known as a blood clot While the biochemical conversion of fibrinogen to fibrin by the action of thrombin has been described in some detail the conversion of prothrombin to thrombin is not so well understood[1] The latter process may be investigated experimentally by partial activation of prothrombin, which reduces its capacity to form thrombin, and subsequent regeneration of prothrombin-like activity so that thrombin can be formed The work described here reports the capacity, hitherto unrecognized, of plasma albumin and globulin fractions to regenerate prothrombin-like activity from a partially active prothrombin derivative

Ware and Seegers[2] were the first to observe that a substance exhibiting prothrombin-like activity could be generated from a partially active prothrombin derivative The reaction was afterwards observed by others[3-8] The partial activation of prothrombin and subsequent regeneration of a substance exhibiting prothrombin-like activity, referred to as prothrombin-*R*, provides an experimental model for testing the effects of enzymes and other plasma protein fractions which may be serving as clotting factors in the process of converting prothrombin to thrombin

To examine systematically the influence of the plasma albumin and globulin fractions on the formation of prothrombin-*R*, a series of experiments was conducted using Cohn plasma fractions and plasma fractions purified by DEAE-cellulose anion exchange chromatography Purified prothrombin was prepared from bovine plasma[9], its specific activity was approximately 30,000 U /mgm tyrosine The prothrombin was diluted with Michaelis veronal acetate buffer[10] at *p*H 5 to an activity-level of 1,000 units/ml (ref 11) To obtain the partially active prothrombin derivative, rat liver light mitochondria (lysosomes)[12,13] were added to the prothrombin at the rate of 10 μgm protein/1,000 units prothrombin activity[11] When the activity-level was reduced by half, the reaction was stopped by cooling to − 2° C, centrifuged at 14,000*g* for 10 min to remove the mitochondria, and the *p*H increased to 7 9

DEAE-cellulose anion exchange chromatography[14] (buffer 0 005 *M* triphosphate, *p*H 8 6) was used to obtain α-, β- and γ-globulins and albumin from Cohn fractions III, IV and V (Pentex, Inc, Kankakee, Illinois). The homogeneity of the Cohn fractions and the chromatographed fractions was tested by immunoelectrophoresis[15] Fig 1 presents photographs of the immunoelectrophoretic slides for commercial Cohn fractions III (rabbit origin) and IV (rabbit and human origin), and the chromatographed albumin, β- and γ-globulin fractions (rabbit origin) The fractions which were not chromatographed showed multiple precipitation lines, indicating that they were composed of several immunoelectrophoretically distinguishable protein components The chromatographed fractions showed single precipitation lines, and may be regarded as homogeneous according to the immunoelectrophoresis procedure

Single plasma fractions, both Cohn and chromatographed, were mixed in varying concentrations with the partially active prothrombin derivative and were tested for prothrombin activity[11] immediately after mixing (0 min) and at successive intervals up to 70 min Table 1 presents the experimental data at 0, 30, 60 and 70 min for optimal concentrations of

* On leave from the Indian Statistical Institute, Calcutta

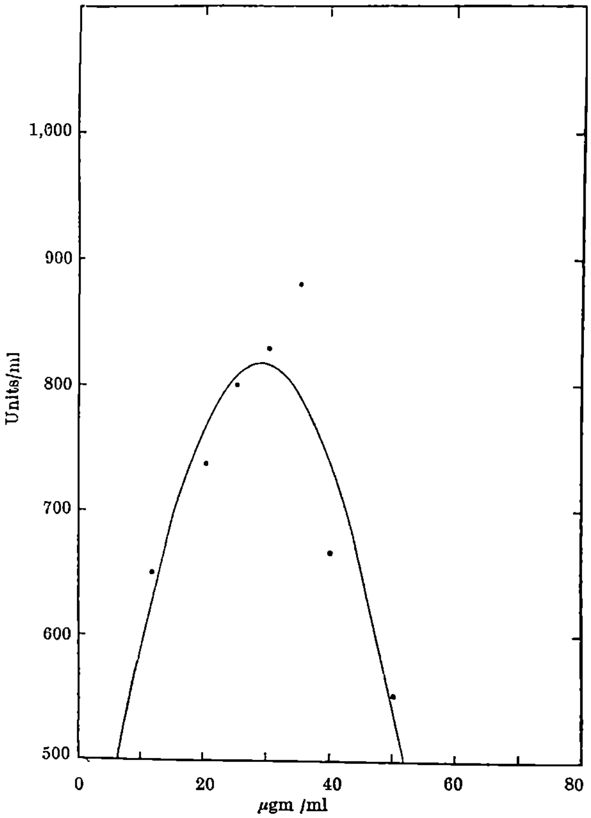

Fig 2 Regenerated prothrombin activity at 60 min in relation to the concentration of Cohn fraction II The ordinate gives prothrombin activity in units/ml, and abscissa gives protein concentration of the plasma fraction in μgm /ml The parabolic curve gives the expected yield of prothrombin-*R* and the points give the observed yield of prothrombin-*R*

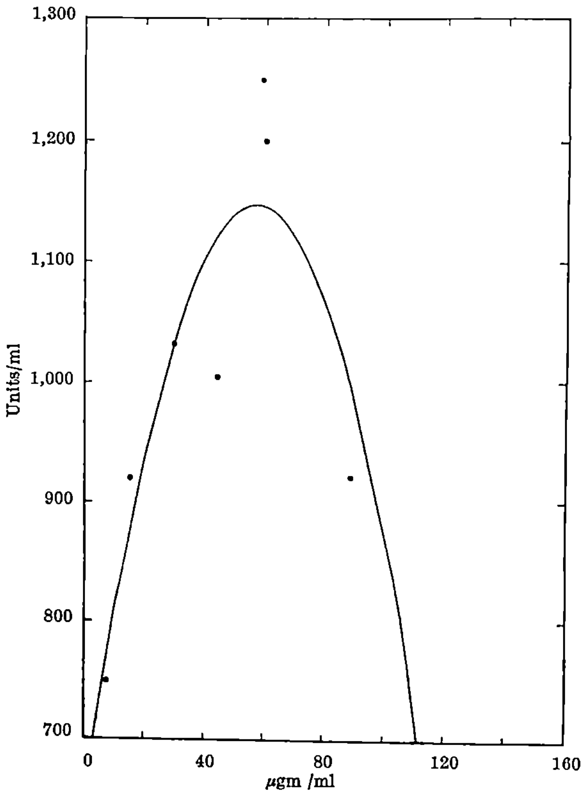

Fig 3 Regenerated prothrombin activity at 60 min in relation to the concentration of DEAE-cellulose chromatographed β-globulin (See Fig 2 for further explanation)

the fractions and for selected lower and higher concentrations The prothrombin activity of fractions at 60 min was found to be a parabolic function of the protein concentration of the plasma fraction, and Table 1 presents the parabolic equations fitted to all the experimental data by the non-reduction method of least squares[16]. Figs 2 and 3 present the expected amount of prothrombin activity as a curve, and the observed data as points, for Cohn fraction II and for purified β-globulin The prothrombin activity at 60 min can be expressed as a percentage of the activity of the prothrombin derivative prior to mixing it with the plasma fraction, these percentages are also given in Table 1, and they represent the amount of prothrombin activity regenerated by the plasma fraction

Although the chromatographed fractions were distinguishable by immunoelectrophoresis, they all exhibited the capacity to generate prothrombin-*R* It may be postulated that the agent responsible for this capacity is an enzyme differentially distributed among the globulin fractions The major findings of

* $\hat{Y}$ = Expected prothrombin activity. X = Plasma fraction concentration

these experiments, as shown by Table 1, may be examined in terms of this hypothesis First, albumin was less effective than the globulin fractions in regenerating prothrombin activity Second, the commercially prepared Cohn fractions were uniformly less effective in regenerating prothrombin activity than the chromatographed fractions, both in terms of the percentage of prothrombin activity regenerated, and the protein concentration required to achieve the maximum observed regeneration This may have been due to the presence of multiple protein components in the Cohn fractions, some of which may have been acting as inhibitors of the active agent Third, the chromatographed globulin fractions exhibited differing amounts of activity, as indicated by the protein concentration required to achieve 100 per cent regeneration Fourth, as the parabolic equations indicate, activation of the prothrombin generating mechanism increases with the protein concentration of the plasma fraction, while inhibition of the mechanism increases with the squared concentration value As enzymes typically activate and inhibit reactions in this matter, the interpretation of the active agent as an enzyme is also compatible with the observed relationship The similarity observed for the globulin fractions in the regeneration of prothrombin activity is consistent with published findings that the globulin fractions are highly intercorrelated and exhibit a similar degree of relationship with serum cholesterol and serum inorganic phosphorus[17]

SCRAPIE IN SHEEP: THE HEREDITARY COMPONENT IN A HIGH INCIDENCE ENVIRONMENT

By G J. DRAPER and H B PARRY

Unit of Biometry and Nuffield Institute for Medical Research, University of Oxford

IN a previous communication[1] one of us showed that natural scrapie in sheep was likely to be due to an autosomal recessive gene *s* A more comprehensive study[2] added further support for this genetic hypothesis and provided evidence against the supposition that environmental factors influence materially the clinical manifestation New evidence, consistent with these results, collected in a high-incidence flock among progenies of different sires has permitted a rigorous statistical analysis

The material and methods have been described[2,3] From flock *A*, in which the annual incidence of scrapie from 1957 to 1962 was 16 7, 7 5, 14 8, 10 9, 13 6 and 12 3 per cent, data on the attack-rate are available for (*a*) 14 females of the same breed and similar breeding introduced in 1959 from a flock free of scrapie then and since The 14 were aged 9 months to 6 years, after 2¾ years 12 are well and no sign of scrapie has appeared in any of the 14 or their progeny (*b*) 181 progeny born to the 10 stud rams used in the flock in 1957–58 and 1958–59, reared and kept in the flock, of which 75 have developed scrapie All females surviving to 9 months of age and able to breed have been retained, as well as all males of *ss* × *ss* matings Retention of males of other types of mating has not been complete, and, as the basis on which they were retained might introduce bias into the analysis, they have not been included, although the data for 7 such animals are consistent

Of the 10 stud rams the presumptive genotypes of 5 are *ss*, 4 being affected and 1 having both parents affected Three rams are unaffected and are presumptive *Ss* or *SS*, the genotype of two can be allotted on pedigree and other outside data, while that of the third is uncertain without using data from the 1958–59 birth-group, and the results of his 13 progeny have therefore been excluded, although they indicate this ram to be *Ss* Two rams died of competing risks and their 24 progeny have also been excluded However, the results on the progenies of these 3 rams are entirely consistent with those of the 7 The presumptive genotypes of the dams are also determined by reference to data other than that presented here

The effect on our conclusions if some of these presumptive genotypes are incorrect must be considered In the first part of the analysis here we show that the discrepancies between the observations and expectations based on the genetic hypothesis can be ascribed to chance It seems probable that mistakes in the genotyping would tend to increase these discrepancies, such mistakes would therefore not be in a direction to affect our conclusions Nor does it seem that any systematic bias could be introduced in this way which would vitiate the results of the second part of the analysis

The data may be analysed in two ways We may examine the observations to see whether they are consistent with the recessive gene hypothesis We may also try to determine whether there are any real differences in the proportions of affected progeny from different types of mating, to test various contagion hypotheses The results of both types of analysis support the genetic hypothesis

Table 1 gives data on the fate by age 3 years of the 137 sheep alive and well at age 9 months (This latter age is chosen to eliminate the special effects of normal wastage in early life) The first figure in each cell is the number of progeny, from the indicated type of mating, in which scrapie has manifested by the age of 3 years The second figure is the number which were either alive and free of scrapie at age 3 or had died from other causes by that age Similar data at age 4 years are presented in Table 2

Table 1 NUMBERS OF OFFSPRING* MANIFESTING SCRAPIE, AND THOSE REMAINING FREE OF IT†, AT AGE 3 YEARS, FROM VARIOUS TYPES OF MATING

		Ewe				
		Affected during gestation/ lactation	Affected later	Presumptive *ss*	Presumptive *Ss*	Presumptive *SS*
Ram	Affected	6, 6	9, 10	—	8, 37	0, 10
	Presumptive *ss*	3, 1	6, 3	1, 1	0, 3	0, 1
	Presumptive *Ss*	—	1, 2	—	0, 2	—
	Presumptive *SS*	0, 8	0, 10	—	0, 8	0, 1

* The first figure in each cell is the number of affected offspring and the second is the number free of the disease (all by age 3 years)

† The criteria for inclusion in the table and of assessment are given in the text

Table 2 NUMBERS OF OFFSPRING MANIFESTING SCRAPIE AND THOSE REMAINING FREE OF IT, AT AGE 4 YEARS, FROM VARIOUS TYPES OF MATING (SEE NOTES ON TABLE 1)

		Ewe				
		Affected during gestation/ lactation	Affected later	Presumptive *ss*	Presumptive *Ss*	Presumptive *SS*
Ram	Affected	2, 1	11, 4	—	8, 12	0, 4
	Presumptive *SS*	0, 3	0, 9	—	0, 7	0, 1

(1) We first examine the data to see whether they are consistent with the postulated genetic theory

The age of manifestation of the disease is highly variable The manifestation-level $\lambda(t)$, at age t, is defined here to be the proportion of all animals alive at age 9 months and homozygous for the postulated scrapie gene in which the disease actually appears by age t This definition differs from one used previously[1,2].

For some types of mating for which data on the offspring are available, it is possible to estimate $\lambda(t)$ if the genetic hypothesis is assumed true But it is not then possible to test the hypothesis itself If, however, data are available on the fate, by age t, of progeny from two or three different types of mating we may obtain a combined estimate of $\lambda(t)$ and then test the hypothesis using a χ^2 test which has one degree of freedom fewer than the number of types of family[4] More precisely, we estimate $\lambda(t)$ from the data, assuming the hypothesis, compute, using this estimated value, the expected number of affected (by age t) animals from each type of mating, and then use χ^2 to compare these expectations with the observed values

Data for estimating λ at age 3 years are available on three types of mating (Table 1) However, since there are only 2 progeny from matings of type *Ss* × *Ss* we cannot incorporate into the analysis the information which they provide (For the χ^2 test is invalid for such low numbers The value of λ is barely affected by this exclusion) The estimate of λ from the remaining two types of mating is $\lambda = 0\ 49$ On testing for 'goodness-of-fit' using this estimate we find $\chi^2 = 1\ 82$ with 1 d f Thus the data fit the hypothesis well

The fate of the male progeny born in the *ss* × *ss* group was very similar to that of the females This is also true of the few male animals from other matings which were kept under observation (but which are not included in the table)

Data for estimating λ at age 4 years are again available from two types of mating, all the progeny except one being female (Table 2) The combined estimate of λ at this age is 0 74 and the value of χ^2, with 1 d f, is 0 11, showing very good agreement between data and theory

Thus the recessivity hypothesis provides an adequate explanation of the observed data

(2) We next examine Tables 1 and 2 to ascertain whether differences in the proportions of affected animals from different types of mating are consistent with hypotheses based on transmission of the disease either by contagion or by one of the parents

The following discussion is based on the classification at age 3 years (that is, on Table 1) Less information is available regarding animals of 4 years, such conclusions as can be drawn are similar and are indicated later

On examining the first two columns of Table 1 and comparing, for each row separately, the pairs of figures in the two columns, it seems evident that there is no difference in the fate of the offspring of mothers affected by the disease during their gestation and/or suckling and those of mothers affected later

From the first two columns, taken separately or together, we may examine the proportions of affected progeny in matings involving rams of different presumptive genotype Taking both columns together, that is, considering the progeny from all affected females and comparing the proportions of affected animals arising from matings with different types of ram we find the following differences (ignoring the progeny of the presumptively *ss* ram) (Here and later we shall be using χ^2 to test for differences in the proportions of affected progeny from indicated pairs of matings)

Progeny from affected rams compared with progeny from presumptively *SS* ram, $\chi^2 = 10\ 38$

Progeny from affected rams compared with progeny from presumptively *SS* and *Ss* rams, $\chi^2 = 9\ 23$

Each of these χ^2's indicates a highly significant difference The probabilities that the observed differences are due to chance are respectively 1 in 700 and 1 in 400 Similar results are obtained, though at lower levels of significance, if we examine separately the results from the two types of affected ewes

From the parallel results for affected rams mated with various types of ewe similar conclusions may be drawn There are significant differences between the progeny born to affected ewes and those from either presumptive *Ss* or presumptive *SS* ewes If the latter two groups are taken together and compared with the progeny of affected ewes (all the rams being affected) the difference is significant at the 1 in 500 level Taking the two types of affected ewe separately we obtain similar results, but at a lower level of significance

Examination of the top two rows of Table 1 suggests there is no difference in the proportions of affected animals born to the ram believed on purely familial grounds to be of type *ss* and those born to rams actually affected

Similar conclusions may be drawn from Table 2

It should be noted that of 38 animals having a presumptive *SS* animal for a parent not one was affected by the disease

In assessing these results, two points should be borne in mind First, the various significance tests are not independent, this, however, does not vitiate the nature of the conclusions Secondly, the number of rams involved was small, and in particular there was only one presumptive *SS* ram However, the following conclusions may be drawn

(*a*) The hypothesis that the disease is controlled by an autosomal recessive gene provides an entirely adequate explanation of these data

(*b*) The transmission of the disease does not depend simply on whether the ewe is affected, but, for both ewes affected at the time and those affected later, depends also on the ram

(*c*) The chance of an affected ewe transmitting the disease to her progeny is the same whether she is affected at the time of their gestation and/or suckling, or does not become so until later

(*d*) The proportion of affected progeny from affected rams depends on the presumptive genotype of the mother No difference was observed between the progeny from later affected rams and that from one believed on purely familial grounds to be of the same genotype

(*e*) Paragraph (*b*) and the first part of (*d*) state that transmission of the disease does not depend on either parent alone However, the significance tests provide at least equally strong evidence that the probability of an animal becoming affected is not determined simply by the general environment

(*f*) The differences noted here are all in the direction which would be predicted on the genetic hypothesis

(*g*) In the dissemination of scrapie among sheep under natural conditions the hereditary component is paramount, and the role of contagion, even if it exists, for which we can find no evidence, is extremely small

(*h*) The control of scrapie could be effected by the use of rams of *SS* genotype Such a ram is the presumptive *SS* of Table 1, which may be considered to be of 'proved' homozygous dominant genotype, for the data suggest that the odds against this ram carrying the allele *s* are probably at least 100 to 1

INCORPORATION OF ASSIMILATED CARBON INTO THE WALLS OF XYLEM ELEMENTS

By DR. H. JONES and J. E. EAGLES

Department of Botany, University College of Wales, Aberystwyth

MANY tracer studies with carbon-14 have shown that the carbon taken up by the leaves of a plant is soon distributed widely within it[1-3] Autoradiographs taken during such investigations have been concerned mainly with the demonstration of the translocatory channels and sinks However, autoradiographs of tissues where soluble carbon has been removed are also potentially useful in studies dealing with the growth of cell walls This is particularly so with respect to wood growth since the comparatively large amount of incorporation of carbon-14 into the massive walls of lignified xylem is especially noticeable in autoradiographs[4]

The distribution of carbon-14 in xylem walls in various parts of the tobacco plant following assimilation of $^{14}CO_2$ by one of the older leaves is being investigated An account of some of the preliminary findings follows

22 mg of $^{14}CO_2$ and $^{12}CO_2$ (about 80 μc) were circulated over a single illuminated leaf of each of three plants of tobacco (var White Burley) using similar apparatus and under similar conditions to those described by Jones *et al* [4] The $^{14}CO_2$ was assimilated in about 0 5 h, the leaf chamber remaining in position for about 2 h Afterwards the plants remained in light and normal air for the periods indicated in Table 1. After five days one of the plants was allowed to assimilate a second quantity of $^{14}CO_2$ (similar quantity and activity to the same leaf) Samples from stems and leaves of the three plants were killed and fixed in formalin/propionic acid/ethanol, then dehydrated through an ethanol series prior to embedding in wax Sections were then cut, dewaxed and taken down to water through a series of decreasing concentrations of ethanol At this point sections were either dried and exposed to Kodak X-ray film or exposed to Kodak *A R* 10 autoradiographic stripping film in the usual way. Sections prepared in this manner show no loss of activity on prolonged contact with water, and it is assumed that the remaining activity is located in the structural cytoplasmic and cell-wall constituents together with inclusions such as starch

Table 1

Plant	Period in light and normal air subsequent to $^{14}CO_2$ assimilation
A	5 days
B	10 days
C	5 days, then second $^{14}CO_2$ assimilation period followed by further 5 days in light and normal air

A marked localization of activity occurs in the petiole of the presentation leaf and of petioles of leaves above this point This results in tangential arcs of active xylem, often only 1 cell deep in a radial direction This feature is evident, though to a lesser extent, in the younger, rapidly growing parts of the stem. Below the presentation leaf (*n*), on the other hand, where the stem has finished extending and contains a large amount of wood, activity is more diffuse in a radial direction (Fig 1) The level of activity is also higher in the older stem

These differences are probably related to differences between the lignification of early formed wood and of that formed later In the former, wall growth appears to be a concentrated process whereby one element is dealt with completely before the next one is started, whereas, in the latter, wall growth is a more diffuse process, where many elements are simultaneously concerned It is possible that these differences are correlated in some way with the different types of lignified elements produced—that is, annular thickening on one hand (in the petioles) and pitted on the other with the inclusion of many fibres The fact that there is marked localization of carbon-14 in walls of xylem elements at a certain growth stage is particularly well seen in Fig 2c Here, the activity is concentrated in two tangential bands each mainly corresponding to a single arc of xylem elements separated by one or two relatively inactive elements Each of these arcs is related tó a single feeding period of $^{14}CO_2$ and corresponds to the arcs in Figs 2*a* and *b* In Fig 2*c*, where two inactive elements separate the active ones, the period of maximum deposition of carbon is probably between $1\frac{2}{3}$ and $1\frac{1}{4}$ days per element Where one inactive element interposes then the values lie between $1\frac{2}{3}$ and $2\frac{1}{2}$ In the stem below leaf $n - 2$, the two peaks of activity are separated by a distance which is between two and three times that between peaks in the petiole of leaf $n + 5$ The greater distance includes about 20 fibres (vessels are few and scattered) so that the time of maximal carbon deposition in any one fibre can be as short as 6 h This procedure, then, affords a method of investigating rates of xylem growth Fisher[5] used a similar method to label young leaf primordia at a certain stage of development and thus to calculate the plastochron

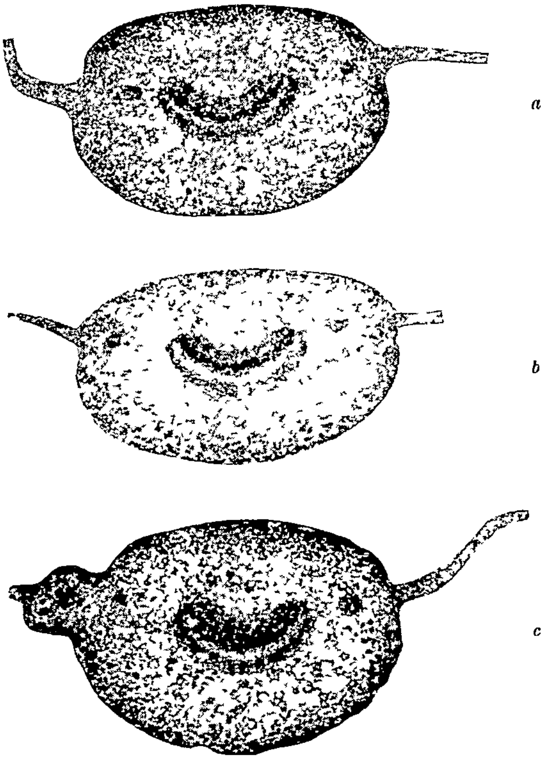

Fig 2 Autoradiographs on Kodak X-ray film of transverse sections of petioles of the fifth leaf above the presentation leaf of plants treated as indicated in Table 1 *c* shows two bands of radioactive xylem elements corresponding to the incorporation of carbon-14 from the two assimilation periods (× *c* 8 5)

A further point arises from the marked localization of the activity in the younger parts of the plant While this is certainly incorporated in the walls, the elements while they were growing must have contained appreciable amounts of soluble carbon-14 It has been clearly established[6] that the xylem transports soluble carbon Most of this material may well be carried in those elements which are undergoing rapid cell wall growth Hylmo[7] has suggested that movement of solutes (referring particularly to inorganic solutes) occurs solely through that part of the xylem which still has cytoplasm on the longitudinal walls but where the transverse walls have broken down Preston[8] with reference to trees has concluded "that the living xylem only is involved in water transport, that is, the xylem in the outermost annual ring only, and even only the outermost elements in it". The zone of maximal incorporation (in younger parts of the plant) may well be the zone of maximal water and solute uptake in the xylem This situation appears to differ markedly from that in the older parts of the tobacco stem There the wide zone of activity indicates that a considerable part of the xylem remains capable of synthesizing new wall material

This work forms part of a project supported by a grant from the Department of Scientific and Industrial Research, the assistance of which is gratefully acknowledged

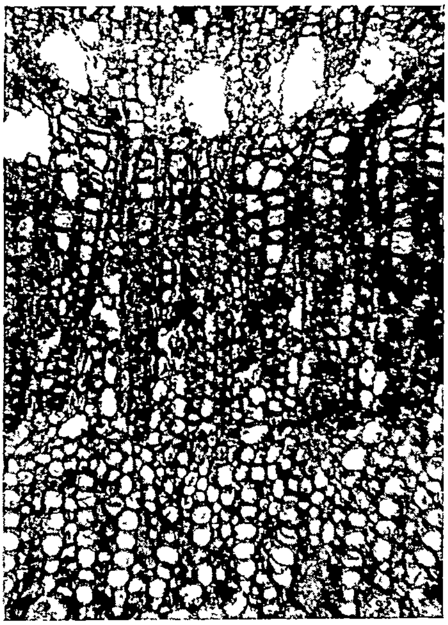

Fig 1 Kodak *A R* 10 stripping film autoradiograph superimposed on transverse section of tobacco stem (taken from the third internode below presentation leaf of plant *C* (Table 1)) The dark area is a wide band of xylem where the walls have incorporated carbon-14 (× *c* 93)

INITIAL RESPONSE OF THE HEART-RATE OF A GASTROPOD, *ACMAEA LIMATULA*, TO ABRUPT CHANGES IN TEMPERATURE

By Prof EARL SEGAL
Department of Biology, Rice University, Houston, Texas

CONSIDERABLE information is available on the later stages of rate responses in poikilotherms to changes in temperatures, that is, from the period of steady state activity at the new temperature to the period of compensation or acclimatization[1-3] But, the initial response to temperature change is much neglected and little understood Many, but not all, investigators have reported that when various cold-blooded animals are subjected to a rapid increase or decrease in temperature they respond with an overshoot or undershoot in one or more activity rates before stabilizing at a rate characteristic of the new temperature Much of this work has been reviewed recently by Grainger[4]

In this investigation, changes in heart-rate after abrupt temperature steps were recorded in the aspidobranch gastropod *Acmaea limatula.* The experiments were carried out on populations of limpets from different habitats (Los Angeles and San Diego, California, and Punta Banda, Baja California) and at different times of the year Although individual differences in heart-rate due to size, season, previous thermal history, and general living conditions are known to be important[5], for the present study these differences have been masked by averaging the various response measurements for any given group under any given experimental conditions

The technique for revealing the heart has been reported on elsewhere[6] Limpets which had shown no post-operative effects after a minimum of 24 hr were placed two to a chamber, in a constant temperature water bath for a number of hours When the steady state of heart-rate was evident, the water in the animal chamber was poured off and replaced by water at the new temperature At the same time, the chamber was transferred to a second water bath at the new temperature The time taken to effect the change was 10–15 sec Controls were run by transferring animals to a second water bath at the same temperature as the first bath (29° C) The control animals[6] showed no greater variation in rate than was usual for that temperature Neither was there a greater variation in rate for a second control group (8 animals) which remained in the original water bath A third control group was maintained in constant temperature rooms at 18 2° and 26 5° C , then the water in the chambers was poured off There was no significant difference between the rates in water and in air Thus, it may be concluded that the experimental changes in heart-rate are due to the temperature change and not to the technique used to effect the change As a further control, heart-rates of two groups of limpets (10 and 14 animals) were counted at 15° and 24 5° C over a 48-hr period There was no discernible diurnal rhythm of heart-rate activity in either group Therefore, the time of day when the animals were subjected to the temperature changes did not affect the rate

Table 1. Overshoot and Undershoot (beats/min) and the Percentage Overshoot and Undershoot of *Acmaea limatula* subjected to abrupt Increases and Decreases of 4°, 9°, and 14° C.

Overshoot or undershoot is the difference, in beats/min , between the fastest or slowest rate achieved by an animal and its stabilized rate some hours after the temperature step

Temp step	No of animals	Overshoot and undershoot (beats/min) Mean	Overshoot and undershoot (per cent) Mean
Increase			
25–29° C	10	16 1	19 0
20–29	26	33 2	39 0
15–29	21	52 0	70 2
	*10	(41 0)	(48 2)
Decrease			
29–25° C	10	12 4	15 2
29–20	14	21 6	30 9
29–15	10	12 1	27 6
29–15	8	14 1	27 0

* Calculated on basis of stabilized rates of 10 animals which were permitted to remain at 29° C for 6 hr after the temperature change. Other animals in this group were subjected to a 14° C decrease 4 hr. after the initial temperature increase

Fig 1 shows the change in heart-rate, with time, of 3 individuals subjected to a 4°, 9° and 14° C. abrupt increase and decrease in temperature The response of these individuals is representative of the group at each experimental situation It can be seen that the response to an increase in temperature is an

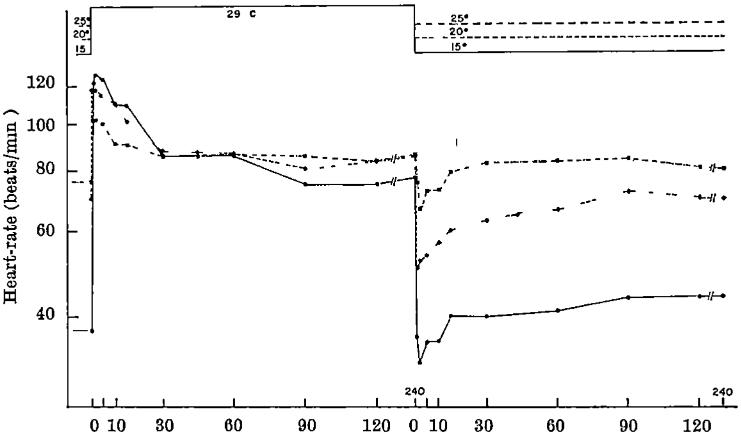

Fig 1 Semi-logarithmic plot of heart-rate (beats/min) as a function of time for three *Acmaea limatula* subjected to abrupt increase and decrease of 4° (■), 9° (◆), and 14° C (●) These individuals are representative of the group subjected to each of the temperature increments Stable heart-rates were recorded for 2 hr before initial temperature increase Animals obtained from rocky inter-tidal at Palos Verdes, California Experiments conducted a minimum of one day after collecting and trephining Animals kept in the meantime in running sea-water at 20° C

Table 2. OVERSHOOT (BEATS/MIN) AND PERCENTAGE OVERSHOOT OF 4 *Acmaea limatula* INDUCED INTO VIOLENT LOCOMOTOR ACTIVITY BY STIMULATION WITH ISOLATED TUBE FEET OF THE STARFISH *Pisaster ochraceous*

Overshoot is the difference between the fastest rate achieved by an animal and its stabilized rate some hours after stimulation Heart-rates could not be counted until 2 min after stimulation

Rate at 29° C (beats/min)	Overshoot (beats/min) (2 min)	Overshoot (per cent)
85 7	6 6	7 7
85 7	6 6	7 7
75 0	10 7	14 2
70 6	4 4	6 2
	Mean	8 9

overshoot in the heart-rate, the response to a decrease in temperature an undershoot in the heart-rate The peak frequency, over or under, is reached within 1 min , occasionally within 2, rarely over 2 The greater the temperature increment, the faster the frequency at peak of overshoot and the slower the frequency at peak of undershoot In general, the greater the temperature increment the longer it takes the heart-rate to stabilize at the new level It takes approximately 6 hr to return to a stable state after a 14° C increase in temperature In these animals the heart-rate shows a full cycle oscillation, the overshoot is followed by an undershoot before reaching a stable rate (Fig 1 and Table 1)

In this investigation the overshoot and undershoot is the difference, in beats/min , between the fastest or slowest rate achieved by an animal and its stabilized rate after the temperature step The greater the increment necessary to reach the same new higher temperature, the greater the overshoot In contrast, when animals at the same temperature are subjected to various lower temperatures (4°, 9° and 14° C), the undershoot in response to a 9° C drop is greater than that due to a 4° C drop, but the undershoot in response to a 14° C drop is not very different from the undershoot in response to a 9° C drop (Table 1)

To determine what portion of the overshoot may be due to the increased locomotor activity associated with the rise in temperature, 4 individuals at 29° C were induced into violent locomotor activity by being stimulated with isolated tube feet of the starfish *Pisaster ochraceous*[6] Heart-rates were arhythmic, steady rates could not be obtained until 2 min after stimulation The mean per cent increase in heart-rate was 8 9 per cent (Table 2), which was less than half shown for the animals subjected to a 4° C rise in temperature After stimulation it took approximately 15 min for the rates to return to normal although the animals were still active At first it appears that for the same temperature increments 'overshoots' are greater than 'undershoots', however, when the rate increase due to locomotor activity is subtracted from the overshoot, overshoot and undershoot to a 4° and 9° C increment are practically mirror images. This is not true for the 14° C increment

Another facet of the overshoot phenomenon is that the same temperature increment causes a greater overshoot at higher temperatures (Table 3) Thus a 9° C increase between 11° and 20° C. produces a 10 per cent overshoot while the same increment between 20° and 29° C produces a 39 per cent overshoot

Table 3 OVERSHOOT (BEATS/MIN) OF *Acmaea limatula* SUBJECTED TO AN ABRUPT INCREASE OF 9° OR 14° C. OVER DIFFERENT PORTIONS OF THE TEMPERATURE SCALE

Overshoot is the difference between the fastest rate achieved by an animal and its stabilized rate some hours after the temperature step

Temp step	No of animals	Overshoot (beats/min) Mean	Overshoot (per cent) Mean
20–29°	26	33 2	39 0
17–26	10	28 1	39 5
16–25	12	21 1	30 2
15–24	7	22 0	27 1
11–20	10	6 0	10 5
15–29	21	52 0	70 0
	*10	*(41 0)	*(48 2)
11–25	34	18 1	25 8
10–24	10	18 5	24 3

* Stabilized rate after 6 hr at the new temperature For all other animals figures are for stabilized rates after 3–4 hr at the new temperature

Nothing is known about the cardioregulatory nerves in *Acmaea* Nor can a distinction be made between the direct effect of rapid temperature change on the heart and any indirect effects resulting from an alteration in the physiological state of the animals A physiological explanation for the overshoot awaits further examination However, it is difficult to see how the overshoot or undershoot can have any functional significance in terms of temperature adaptation It is more probable that an abrupt temperature change produces a temporary imbalance in certain physiological systems (nervous, and less likely, hormonal) and the overshoot or undershoot are merely incidental to the adjustments that are forced on the animal

RELATIONSHIP BETWEEN THE LETTUCE BIG-VEIN VIRUS AND ITS VECTOR, *OLPIDIUM BRASSICAE*

By PROF R N CAMPBELL

Department of Plant Pathology, University of California, Davis

BIG vein of lettuce (*Lactuca sativa* L) is caused by the big-vein virus[1–3] that is transmitted by a chytrid fungus, *Olpidium brassicae* (Wor) Dang [2,3], or by grafting[1,3], but not by mechanical methods[2,3] It has been shown that an isolate of *Olpidium* that could not transmit the causal agent of big vein could acquire what I consider to be the big-vein virus from the roots of graft-inoculated plants and transmit it to healthy plants[4] The reported survival of big-vein virus in air-dry soil for 8 years[5] could be due to survival of big-vein virus within *Olpidium* resting sporangia, to adsorption of big-vein virus on clay particles, root tissues or resting sporangia, or to accidental contamination by *Olpidium* and big-vein virus[3] This article presents evidence that the big-vein virus survives within the resting sporangia of *Olpidium* and does not multiply within its vector An abstract is in the press[6]

Roots of *Olpidium*–big-vein-infected plants grown in sand culture were washed free of sand, air dried and stored in the laboratory for 2–5 months Resting sporangia were extracted from the roots and treated as follows The dry roots that contained numerous resting sporangia were pulverized in a mortar, tap water added and the fine particles were washed successively through 100-, 250- and 400-mesh screens The material remaining on the 100-mesh screen was re-ground in the mortar and washed through the same screens

The resting sporangia in the material which passed the 400-mesh screen were concentrated by centrifugation at 5,000 r p m for 10 min in either the *GSA* or *SS*34 rotors of a Servall centrifuge, re-suspended in a small volume of tap water, and divided into three aliquots that were given these treatments (*a*) untreated checks, (*b*) acidified with 1 0 *N* or concentrated hydrochloric acid to *p*H 0 5 for 2 hr (*p*H determined with a Beckman zeromatic *p*H meter), (*c*) incubated for 30 min in an equal volume of 20 per cent aqueous trisodium phosphate (w/v) The *p*H of each suspension was checked near the end of the treatment period, it ranged from *p*H 0 6 to 0 8 for the acid treatment, *p*H 7 2–8 1 for the untreated checks, and *p*H 11 3–12 3 for the trisodium phosphate treatment These treatments were selected because they are known to inactivate tobacco mosaic virus, one of the most stable plant viruses, in the seedcoats of tomato seeds (*Lycopersicon esculentum* Mill)[7]

The tubes containing the resting sporangia treatments were incubated at room temperature with occasional stirring and, at the end of the specified treatment time, the resting sporangia were sedimented by centrifugation and re-suspended in 20 ml of tap-water The resting sporangia from each treatment were poured on to a single pot of pasteurized quartz sand in which many lettuce seeds were sown immediately An un-inoculated seedling pot was planted as a check for each pot inoculated with resting sporangia All the pots were placed on the same greenhouse bench with the un-inoculated check pots interspersed among the inoculated pots The cultural methods have been described[3]

Three weeks after the seeds were sown, the seedlings were removed from each pot and four randomly selected seedlings were transplanted individually to pots These are referred to as 'transplanted seedlings' Root washings were made from the roots of the remainder of the seedlings, examined for *Olpidium* zoospores[3], and poured around two healthy lettuce seedlings in individual pots These are referred to as 'root washing-inoculated plants' Similar healthy seedlings inoculated at the same time with *Olpidium* zoospores from big-vein infected plants served as positive checks *Olpidium* zoospores were abundant in those root washings in which they were present, it is estimated that each plant inoculated with these root washings received more than 1 × 10^6 zoospores At the end of the experiment each plant was examined for the presence of *Olpidium* by the previously described method[3]

Two experiments were done at different times experiment I consisted of one replicate, experiment II consisted of two replicates that gave the same results and have been combined (Table 1) *Olpidium* survived and transmitted big-vein virus in all three replications of the trisodium phosphate treatment Although *Olpidium* survived the acid treatment and transmitted big-vein virus in experiment I, this treatment eliminated the fungus in both replications of experiment II The reason for this inconsistency in the acid treatment is unknown but could relate to the temperature at which the treatment was incubated A higher temperature in experiment II may have caused faster hydrolysis and more complete dissolution of the walls of resting sporangia *Olpidium* zoospores were present in the root washings made at the time of transplanting in all treatments that afterwards developed big-vein symptoms and were absent from all other treatments At the end of each experiment *Olpidium* was present in the roots of all plants that developed big-vein symptoms and absent from all un-inoculated checks Two plants in experiment II were *Olpidium*-infected but symptomless, whereas the other four plants in the same replicate had symptoms Zoospore transfers are being made to determine whether big-vein virus can be transmitted from these plants

The first symptoms of big-vein appeared in 21 days on the plants inoculated with zoospores in root washings This period was about a week shorter than usually required for symptom development and is due to inoculation with large numbers of zoospores and near-optimum conditions for disease development The first symptoms on the seedlings transplanted from pots inoculated with resting sporangia appeared in 38 days on the fifth or sixth true leaf This corresponds to the pattern of symptom development in the field[8] The increase in the time for symptom expression with resting sporangia inoculum probably is due to the delay in *Olpidium* infection Abundant infections occur with zoospore inoculations within a few hours With resting sporangia inoculations, however, additional time is required for seed germination and for germination of resting sporangia Examination of seedlings from pots inoculated with resting sporangia showed no *Olpidium* infection one week after sowing, but many infections after two weeks Because of the rapid and uniform appearance of symptoms the experiments were terminated 54 days after sowing the seeds or 32 days after inoculation of seedlings with zoospores in root washings

These results show that *Olpidium* and big-vein virus survive in roots air-dried for as long as five months and subjected to strong chemical treatments, and demonstrate again the close relationship between *Olpidium* and big-vein virus transmission It seems

Table 1 SURVIVAL OF *Olpidium* AND BIG-VEIN VIRUS (BVV) IN RESTING SPORANGIAL PREPARATIONS AFTER TREATMENT WITH ACID OR TRISODIUM PHOSPHATE

	Untreated	8/8	4/4	12/12
	Un-inoculated check	0/24	0/12	0/36
	BVV–*Olpidium* check	—	3/3	3/3

* No of plants with big-vein symptoms or *Olpidium* at end of each experiment/number of plants transplanted and/or inoculated with root washings See text for description of plants

† Each treatment was done on resting sporangia extracted from 1 gm (air-dry weight) of roots after storage for 2 months

‡ Each replicate of each treatment was done on resting sporangia extracted from 0 5 gm (air-dry weight) of roots after storage for 5 months

likely that having survived for five months the fungus and virus could survive for years, thus accounting for the survival in air-dry soil for eight years[5] It seems most likely that *Olpidium* survives these adverse conditions as thick-walled resting sporangia rather than as thin-walled vegetative sporangia or zoospores Since big-vein virus survived the strong chemical treatments along with *Olpidium*, it appears most probable that big-vein virus was within the thick-walled resting sporangia If big-vein virus had been external to the resting sporangia it seems likely that it would have been inactivated by treatments that have been shown to inactivate tobacco mosaic virus in tomato seed coats but not in the endosperms[7] Until the nature of the big-vein virus is better known, however, the possibility that the virus itself is in some way resistant cannot be ruled out If this is the case, then big-vein virus could have survived as particles adsorbed on host cell residues or on the exterior of resting sporangia Since the air-dried roots were obtained from plants grown in quartz sand the possibility of virus adsorption and survival on clay particles was obviated Vacuum infiltration of the preparations of resting sporangia by the chemicals was not done and seems unnecessary since the chemicals have strong penetrating action as evidenced by the penetration of dry seed coats of tomato seeds and the destruction of tobacco mosaic virus[7] Therefore, it is concluded that the resting sporangia of *Olpidium* can withstand drying and strong chemical treatments and that the big-vein virus survives within the resting sporangia presumably within the fungus protoplasm Both *Olpidium* and big-vein virus undoubtedly survive in the same manner in the field

In order to study multiplication of the big-vein virus in its vector, *Olpidium* zoospores from the big-vein virus–*Olpidium* culture that had been maintained on lettuce roots for more than one year were transferred to sugar beet (*Beta vulgaris* L cultivar U S 75) seedlings At intervals root washings were made, examined for the presence of zoospores, and re-inoculated to healthy sugar beets and to two lettuce seedlings Big-vein virus was transmitted to both inoculated lettuce plants by the third transfer of zoospores and to one of two plants inoculated with the fourth transfer, but not by the fifth or sixth transfers (Table 2) Other experiments have shown that the zoospores from the first and second transfers would consistently transmit big-vein virus to inoculated lettuce plants After symptomless plants inoculated with the fourth to sixth transfers of zoospores had been incubated for 2–3 months, root washings were made from each plant and transferred to two individual healthy seedlings (the second generation lettuce plants) None of these plants developed big-vein symptoms during a 57-day incubation period whereas both the big-vein virus–*Olpidium* checks inoculated at the same time developed big-vein symptoms within 32 days

Table 2 THE LOSS OF ABILITY OF *Olpidium* TO TRANSMIT BIG VEIN VIRUS AFTER 6 CONSECUTIVE TRANSFERS ON SUGAR BEETS

No of transfers on sugar beets	Incubation period in sugar beets (wk)	Big-vein symptoms on lettuce 1st generation*	 2nd generation†
1	4	not tested	
2	4	not tested	
3	2	2/2	
4	2	1/2	0/2
5	2	0/2	0/4
6	4	0/2	0/4

* 2 plants inoculated with root washings containing zoospores directly from sugar beets

† 2 plants inoculated with root washings containing zoospores from each symptomless plant of the first generation

Although *Olpidium* from lettuce readily infects and reproduces on sugar beet roots, the virus apparently was lost in repeated transfers of the vectors on beet, whereas it has been consistently perpetuated under similar conditions in lettuce These results indicate that sugar beet is probably not susceptible to big-vein virus and that the virus probably does not multiply in the fungus vector, at least not to the extent necessary to perpetuate itself during fungus multiplication It should be noted, however, that big-vein virus was maintained in an infectious state for 12 weeks by actively multiplying *Olpidium* on sugar beets This fact, plus the survival of the virus for 5 months in dry resting sporangia, indicates a high degree of persistence in *Olpidium*

EFFECT OF MATERNAL ISOANTIBODIES ON THE QUANTITATIVE EXPRESSION OF TWO ALLELIC GENES CONTROLLING γ-GLOBULIN ALLOTYPIC SPECIFICITIES

By DR SHELDON DRAY

Laboratory of Immunology, National Institute of Allergy and Infectious Diseases,
National Institutes of Health, Bethesda 14, Maryland

ALLOTYPES are serum proteins which differ in part of their antigenic specificity from one individual to another in the same animal species Allotypes were discovered in domestic rabbits by Oudin in 1956[1] Serum protein allotypes of indivdual rabbits are antigenic for other rabbits and yield precipitating antibodies, these isoantibodies can then be used to identify the allotypes by agar-gel immunochemical methods[1-3] Allotypes have been found among the α-, β- and γ-globulins[2], several $7S$ γ-globulin allotypes have been identified and their genetic control investigated[1-8] The maternal-fœtal barrier of rabbits has been shown to be permeable to these γ-globulin allotypes[3,6,8].

One purpose of this article is to show that, by genetic manipulation, γ-globulin allotypes may serve as natural markers for the disappearance of passively transferred maternal γ-globulin and for the appearance of newly synthesized γ-globulin in the serum of neonatal rabbits A second purpose is to show that maternal isoantibodies to an allotype of the progeny interfere substantially with the ability of the young to exhibit this allotype in its serum and that at the same time there occurs a compensatory increase of the allotype controlled by the allelic gene

The γ-globulin allotypes A5 and A4 (formerly called *RGG* I and II)* are controlled by a single pair of autosomal genes with both specificities exhibited by the heterozygote[4,6,8] Heterozygote A_b^5/A_b^4 dams (with A5 and A4 in their sera) were back crossed to homozygote A_b^5/A_b^5 sires The offspring were either heterozygotes or A5 homozygotes. The A5 homozygotes do not synthesize A4, and thus A4 transferred during pregnancy from the mother serves as a marker for the decay of maternal γ-globulin in the neonatal rabbits

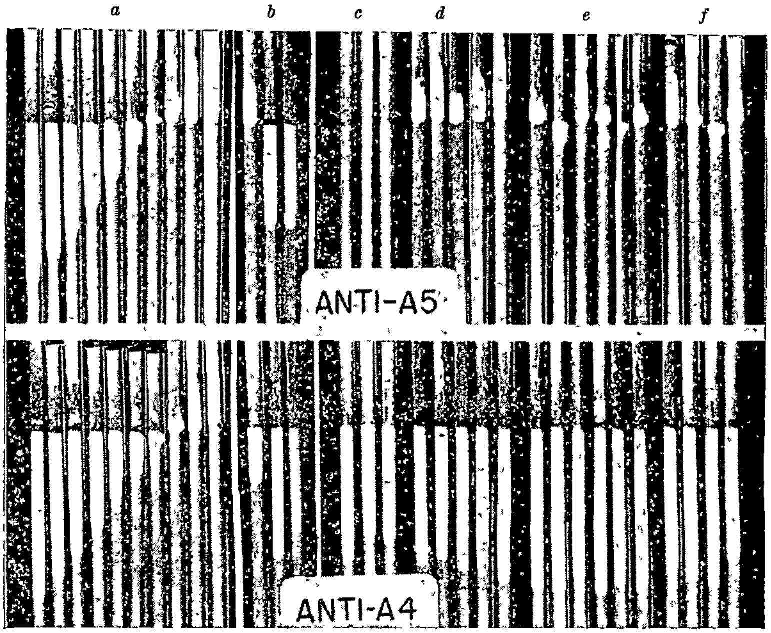

Fig 1 Agar-gel tube analysis with constant concentrations of anti-A5 and of A4 in the bottom layer Top layer as follows *a*, two-fold dilutions of each reference serum with its respective antiserum, *b*, sera from a 4-, 24-, and 56-week-old offspring from non-immunized homozygous mothers, *c*, *d*, *e* and *f*, sera of 9½-, 23-, 42-, and 45-week old litters from immunized mothers

To examine newly synthesized γ-globulin allotypes, male rabbits homozygous for A5 were mated to female rabbits homozygous for A4 All the offspring were heterozygotes exhibiting allotypes A5 and A4 in their sera A5, being absent in the mother, is present in the offspring only as a result of synthesis, but not by passive transfer of maternal γ-globulins as occurs with A4 Finally, homozygous A_b^4/A_b^4 dams after immunization with A5 were also crossed with homozygous A_b^5/A_b^5 sires During pregnancy, the anti-A5 in the mother's circulation is passively transferred to the heterozygous offspring and it is therefore possible to study the effect of anti-A5 on the developing progeny, which genetically would be expected to synthesize A5 This kind of experiment is somewhat analogous to the Rh maternal-fœtal incompatibility in humans which results in erythroblastosis fœtalis

Serum was obtained from the progeny of the aforementioned matings The relative concentration of A5 and of A4 in the sera of the progeny at different ages was determined by Oudin agar-gel tube analysis using an antiserum specific for A5 and one specific for A4 The total γ-globulins were measured with guinea pig anti-rabbit γ-globulin The antisera were used at the highest dilution which provided clearly visible precipitin bands Antisera and antigens were mixed with equal volumes of 0 6 per cent (Noble) agar before layering into Oudin tubes. The tubes were sealed, maintained for seven days at 28° C, and then photographed[10]

Sera from a rabbit homozygous for A5 and one homozygous for A4 were selected for use as reference reagents These two reference sera had the same total γ-globulin concentration Two-fold serial dilutions of each reference serum were examined The migration of precipitin bands (Fig 1*a*) was plotted against the serum dilutions to obtain the two standard curves The concentration of each allotype in the serum of neonatal rabbits relative to the amount of the allotype in the appropriate reference serum was derived from the band migration and the standard curve

Fig 2 shows the relative quantities of A5 and A4 in heterozygote offspring of non-immunized and immunized homozygous A_b^4/A_b^4 mothers Each point on this curve represents the average of 4–7 rabbits The offspring of non-immunized mothers (solid line) show the following (1) A5 is not found in the serum on the first day, is barely detectable at about three weeks and it then rises rapidly in concentration until about 24 weeks when the level remains the same at 22 per cent of the quantity present in the reference A5 homozygote, (2) A4 is present in large quantities in the serum on the first day as a result of maternal transfer, then drops to a minimum concentration at about 5 weeks and, finally, rises rapidly to a concentration about 46 per cent of the reference A4 homozygote, (3) the increase in concentration of A5 and of A4 occurs at the same time In contrast, the offspring of immunized mothers (broken line) show that (1) the appearance of A5 is delayed until 24 weeks, 21 weeks later than normally, (2) once A5 does appear, its concentration remains low for a long period so that even at 44 weeks the amount of A5 is only about 5 per cent of the controls; (3) the concentration of A4 is greater, approximately 1 8 times the amount in the controls

Although the total amounts of γ-globulin are the same in the two reference homozygotes, the absolute amounts of A5 and A4 are not known so that a direct comparison of the amounts of A5 and A4 cannot be obtained from the data presented If it were found (as is likely) that the A5 reference homozygote had about the same quantity of A5 as the amount of A4 and in the A4 homozygote, then the 44-week-old offspring of non-immunized mothers shown in Fig. 2

---

* A paper entitled "The Nomenclature of Allotypy", by S Dray, S Dubiski, A. Kelus, E S Lennox and J Oudin, has been submitted for publication This paper presents a uniform nomenclature that will be used by these authors henceforth Two of the allotypes were designated A4 and A5, A4 was assigned to the *b* gene locus

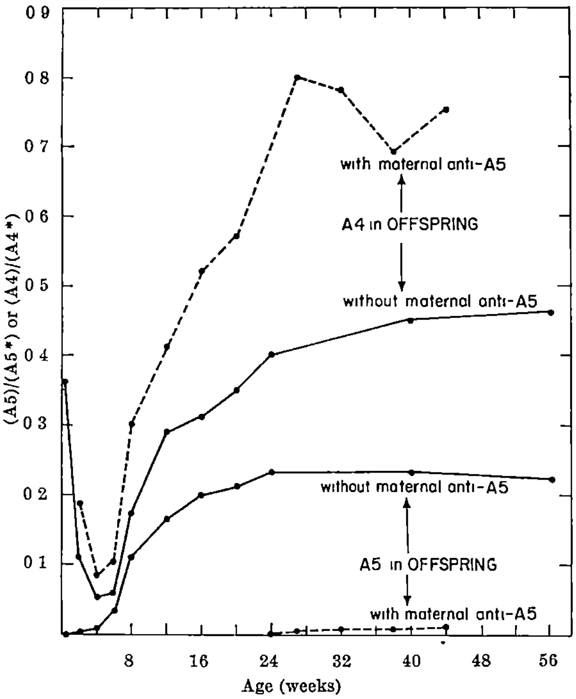

Fig. 2. Relative quantities of A5 and A4 in heterozygote offspring of non-immunized (solid line) and of immunized (broken line) A4 homozygous mothers. A4* and A5* are the amounts of these allotypes in the sera of the two reference homozygotes

would have approximately twice as much A4 as A5 whereas, at the same age, heterozygote offspring of immunized mothers would have approximately 72 times as much A4 as A5.

In another experiment, the sera of 11 heterozygous offspring (age 16 weeks), from the same parents before and after immunization of the mothers, were analysed for allotypes A5 and A4 and for total rabbit γ-globulin. This experiment also showed that A5 was not detectable and that there was a compensatory increase of A4. No significant difference was found in the total γ-globulin level of these two groups.

To date, this phenomenon occurred in all 18 heterozygote rabbits from two immunized homozygous mothers. Fig. 1c–f shows the migration of precipitin bands with uniform concentrations of anti-A5 (upper half) and of anti-A4 (lower half) for the sera of these 18 rabbits from 4 litters (9½, 23, 42 and 45 weeks of age). Fig. 1c shows that the sera of three progeny at 9½ weeks did not even react with anti-A5 whereas they did show substantial precipitin band migration with anti-A4. Most of the 15 reactions shown in Fig. 1*d–f* with anti-A5 occurred in the antigen layer, only with *e*-2, *e*-5 and *f*-3 was there sufficient A5 to migrate into the antibody layer. As also shown in Fig. 1*d–f*, the 15 sera reacted with anti-A4 to give substantial band migration. For comparison, Fig. 1*b* shows typical examples of the migration bands from the sera of 4, 24 and 56 week old offspring from non-immunized mothers.

In the experiments designed to study the disappearance of maternal allotype, it was found that for the first few weeks the curve was similar to that shown for A4 (Fig. 2) except that instead of the concentration increasing at 6–8 weeks, it continued to decrease to the point where the allotype could no longer be detected at about 8 weeks.

For simplification, this article focuses primarily on the two allotypes, Ab5 and Ab4, where *b* designates the gene locus. However, two other γ-globulin allotypes the specificities of which are controlled by alleles at a second gene locus, namely, the *a* locus, could also be followed in the same progeny[7,8]. Thus, in addition to Ab5 and Ab4, the sera of all the progeny were analysed also for Aa1 and Aa2 to ascertain whether these allotypes would serve as a second marker for passively transferred and newly synthesized γ-globulins in neonatal rabbits. The curves were similar when allotypes Aa2 and Ab5 were used as markers for newly synthesized γ-globulins, also the curves were similar when allotypes Aa1 and Ab4 were used as markers for the disappearance of passively transferred γ-globulins. In the studies of progeny from immunized mothers, whereas anti-Ab5 suppressed synthesis of Ab5, it did not suppress synthesis of allotypes controlled at the *a* locus. Double heterozygote progeny, from immunized mothers homozygous at both loci (A^1_a/A^1_a, A^4_b/A^4_b) and with anti-Aa2 as well as anti-Ab5, are under observation to ascertain whether the phenomenon of suppression will occur simultaneously with respect to the allotypic specificities controlled at the two gene loci *a* and *b*.

That maternal antibodies can effect an alteration of the quantitative expression of two allelic genes for such a prolonged period of time is a novel and unexpected finding[11]. The delay in the appearance of A5 as a result of maternal transfer of anti-A5 might superficially appear to be due simply to the reaction of maternal anti-A5 with the neonatal A5 until sufficient A5 is synthesized to neutralize all the transferred antibody. Since maternal γ-globulin was not found in the serum after about 8 weeks, A5 should appear at this time or shortly thereafter if there were no interference with A5 synthesis. Instead, as shown in Fig. 2, A5 appears much later at about 24 weeks. Furthermore, when all the antibody is neutralized, the concentration of A5 would be expected to increase sharply similar to what occurs during the third to twenty-fourth week in the offspring from non-immunized rabbits. This does not occur. Instead, the concentration of A5 remains very low until 44 weeks. Whether the concentration of A5 will eventually reach the normal level of offspring from non-immunized mothers is yet to be determined.

Two alternative hypotheses are being explored. If A5 and A4 were synthesized by the same cell, then antibody would act by suppressing the synthesis of A5 without interfering with the function of the same cell in its synthesis of A4. Moreover, the compensatory increase of A4 would suggest that the substrate available in the cell for the synthesis of A5 has been diverted toward the synthesis of A4. On the other hand, if A5 and A4 are synthesized by different cells, antibody may act by suppressing the proliferation of those cells capable of synthesizing A5. The compensatory increase of A4 could then be explained as an increase in cells which synthesize A4. These alternatives are subject to experimental investigation. For example, preliminary studies[12] have already shown that fluorescent-labelled anti-A5 and anti-A4 will specifically localize A5 and A4 in the tissues. Only A5 was found in the lymph nodes or spleen of A5 homozygotes, only A4, in A4 homozygotes, and both A5 and A4, in heterozygotes.

In a 9-week heterozygote offspring from an immunized mother, the Coons fluorescent antibody technique revealed A4 being actively produced in lymph nodes and spleen, but no production of A5 γ-globulins was demonstrable In two older 'suppressed' heterozygotes, immunofluorescent histological studies showed diminished A5 production consistent with the low A5 serum concentration These preliminary studies[12] support the concept that this suppression is not merely a result of neutralization by antibody but rather a more fundamental suppression of allotype production In addition to further investigation of these heterozygotes, the critical question whether one γ-globulin-producing cell synthesizes both A4 and A5 or just one allotype is also being studied

There are many facets of the maternal antibody effect which require further study, for example, the quantity of antibody needed, the period of time that it must be present, and how long it persists in the tissues Furthermore, would greater quantities of antibody administered for a longer period of time result in complete suppression of A5 or lead to some disease analogous to erythroblastosis fœtalis [9] Should the timing be found restricted to fœtal or neonatal life, the phenomenon could be related to immunological tolerance with the role of antigen and antibody reversed The question whether persistence of antibody is necessary for maintaining the decreased yield of A5 is somewhat analogous to the problem whether antigen must be present to maintain immunological tolerance, a problem which can be attacked by simultaneous genetic manipulation at two gene loci in order to follow the disappearance of maternal γ-globulin and the appearance of neonatal γ-globulin in the same rabbit One also wonders whether the phenomenon can be terminated at any time by injection of antigen or by other means The phenomenon of allotype 'suppression' and associated 'compensation' is interwoven with those of immunological tolerance, protein synthesis, and antibody formation Experiments devised to examine these phenomena are mutually useful

In conclusion, allotypes of γ-globulin may serve as natural markers for the disappearance of passively transferred maternal γ-globulin and for the appearance of newly synthesized γ-globulin in the serum of neonatal rabbits Maternal isoantibodies to an allotype of the progeny greatly interfere with the ability of the young to exhibit the particular allotype in its serum, at the same time there occurs a compensatory increase of the allotype controlled by the allelic gene This effect is still present in rabbits ten months after birth
